Executive Summary

On behalf of Hercules LLC (Hercules), Kennedy/Jenks Consultants Inc. (KJ) prepared this *TNT Project Area Soil Remedial Action Work Plan* (TNT RAWP) outlining a remedial action addressing energetic constituents in soil at Hercules' former Kenvil Works Facility, located in Kenvil, Roxbury Township, Morris County, New Jersey (Facility) (**Figure 1**). Specifically, this TNT RAWP focuses on an approximately 80-acre area in the southwestern portion of the Facility where 2,4,6-trinitrotoluene (TNT) was historically manufactured and is present in soils. **Figure 2** illustrates former Facility operational areas. **Figure 3** illustrates the TNT Project Area.

This TNT RAWP:

- Summarizes the results of previous environmental investigations performed in the TNT Project Area
- Presents pre-design, treatability study, and pilot study data supporting TNT Project Area soil remedy selection/design
- Outlines a remedy for target constituents in soil compliant with New Jersey Administrative Code (N.J.A.C.) 7:26E – New Jersey Department of Environmental Protection's (NJDEP's) *Technical Requirements for Site Remediation* (TRSR) and protective of human health and the environment
- Establishes remedial action objectives and success criteria for the TNT Project Area soil remedy

The remedy for target constituents[1] in TNT Project Area soil is a multi-phase process focused on degrading source mass in soil and mitigating ongoing impacts to underlying groundwater at the Facility.

Historically, TNT and DNT[2] were released to soil via process upsets in the TNT manufacturing area. TNT and DNT exist in soil as crystalline solids varying in size and shape that partition to groundwater. Studies have demonstrated that bioremediation of TNT and DNT source material can achieve complete degradation to inert organic acids (Serrano-Gonzalez et al. 2018, Spain 1995). Bioremediation is most effective when contact with the surface area of target constituents is maximized. As such, the presence of crystalline solids in Facility soil prolongs the overall timeline of a natural bioremediation remedy. The proposed remedy addresses the presence of crystalline solids via a physical processing phase focused on increasing the surface area to volume ratio of the crystalline solids and homogeneity of the soil mixture, facilitating degradation and reducing the bioremediation timeline. Specifically, this first phase of the remedy includes:

> *Excavation and Blending* – The physical process of excavating source material and blending it on the staging pad for processing reduces the physical and chemical variability of material and begins to break down the crystalline solids to increase surface area.

[1] Target constituents refers to TNT, 2,4-dinitrotoluene (2,4-DNT), 2,6-DNT, 2-amino-4,6-DNT (2-ADNT), and 4-amino-2,6-DNT (4-ADNT)

[2] Collective term referring to 2,4-DNT and 2,6-DNT

Soil Processing Plant – The soil processing plant relies on industry standard mining technologies to reduce the grain size of crystalline material, increasing the surface area available for microbial contact and degradation. The processing plant will reduce source mass to physical particle sizes less than 2 millimeters (mm) in diameter, while also segregating larger native rocks (oversize). The resulting material stream (less than 2 mm in diameter), referred to as biofeed and consisting of native material and target constituent source mass, moves on to the ex-situ bioremediation phase while the clean oversize material is stockpile for excavation backfill.

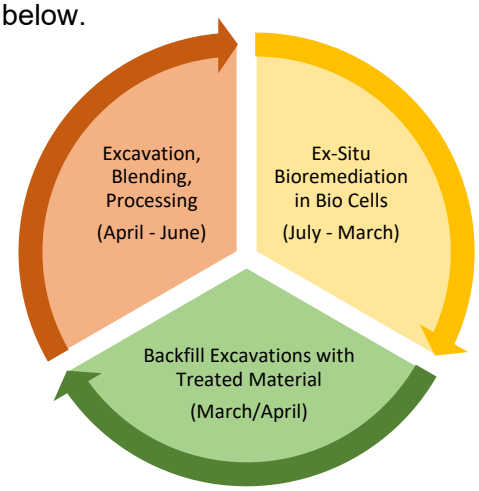
The next phase of the remedy involves the biological breakdown of target constituents in a controlled and monitored environment.

Ex-situ Bioremediation – The biofeed generated by the physical plant processes is amended with a commercially-available amendment (PeroxyChem's DARAMEND OE®) and pumped to containment areas (bio cells), where conditions are managed to facilitate and optimize biological degradation. Treatment in bio cells will achieve NJDEP's non-residential direct contact soil remediation standards (NRDCSRS) and yield a greater than 95 percent reduction in target constituent mass within a single field season (June through October).

The final phase of the remedy addresses in-situ biological degradation to address the remaining target constituent concentrations.

In-situ Biological Degradation – Following the period of management in the bio cells, treated biofeed will be removed and used to backfill the source excavation areas. Target constituent mass remaining in backfilled material will continue to biologically degrade until constituent mass is exhausted. In-situ processes will be monitored, with achievement of remedial goals expected over a 5-year period.

An estimated 70,000 cubic yards (cy) of material[3] requires treatment, approximately 70 percent of which will end up in the bio cells (the remaining 30 percent consists of oversize native aggregate that does not contain target constituent source mass). Treatment involving the first two phases of work (i.e., excavation/blending/processing and ex-situ bioremediation) will occur in a series of annual cycles. The project will require 5 cycles (years) to complete the ex-situ treatment phase. The annual cycle is illustrated below.



[3] Volume estimate is based on 56,000 bank cy of material, and a 1.25 multiplier to estimate loose (excavated) cy.

Target constituent mass will continue to undergo degradation once the treated material is backfilled to excavation areas. Remaining mass will benefit from the residual influences of DARAMEND OE® on in-situ soil conditions and will continue to degrade over approximately 5 years. Degradation will be monitored during both the ex-situ and in-situ phases of work to document the removal of E&E mass and attainment of interim and final remediation goals.

The TNT Project Area will be included in a Facility-wide restrictive covenant (i.e., deed notice) established by Hercules that limits the Facility future uses to industrial/commercial. This soil source mass remedy will address ongoing migration and influences on groundwater quality. Groundwater compliance and associated use restrictions will be addressed via a separate groundwater RAWP.

This TNT RAWP represents a component of ongoing environmental remediation activities at the Facility in fulfillment of a March 10, 1995 Remedial Agreement (RA) between the NJDEP and Hercules, and was prepared in accordance with N.J.A.C. 7:26E – NJDEP's TRSR, N.J.A.C. 7:26C – NJDEP's Administrative Requirements for the Remediation of Contaminated Sites (ARRCS), and NJDEP's Site Remediation Reform Act (SRRA). The Facility is subject to the Remedial Investigation Statutory Timeframe established by the SRRA at New Jersey Statues Annotated (N.J.S.A.) 58:10C-27a(3). A two-year extension of the May 7, 2014 remedial investigation report submission deadline was granted in accordance with P.L. 2013, c.238 (N.J.S.A. 58:10C-27.1), extending the deadline to May 7, 2016. Hercules submitted the Phase II RIR on May 5, 2016 and continues to make progress toward designing and implementing remedies onsite and obtaining associated remedial action permits (RAPs).

Section 1: Introduction

On behalf of Hercules LLC (Hercules), Kennedy/Jenks Consultants Inc. (KJ) prepared this *TNT Project Area Soil Remedial Action Work Plan* (TNT RAWP) outlining a remedial action addressing energetic constituents in soil at Hercules' former Kenvil Works Facility, located in Kenvil, Roxbury Township, Morris County, New Jersey (Facility) (**Figure 1**). Specifically, this TNT RAWP focuses on an approximately 80-acre area in the southwestern portion of the Facility where 2,4,6-trinitrotoluene (TNT) was historically manufactured and is present in soils (the TNT Project Area). **Figure 2** illustrates former Facility operational areas. **Figure 3** illustrates the TNT Project Area.

In May 2016, Hercules submitted the *Phase II Remedial Investigation Report* (Phase II RIR) (Hercules 2016) presenting the results of a multi-phase remedial investigation (RI). The RI identified TNT, associated manufacturing intermediaries (2,4-dinitrotoluene [2,4-DNT], 2,6-dinitrotoluene [2,6-DNT]), and breakdown products (2-amino-4,6-DNT [2ADNT], and 4-amino-2,6-DNT [4ADNT])[4] in soil and groundwater in the TNT Project Area. In response to these findings, Hercules has developed a remedy combining physical processes and enhanced biological degradation to destroy target constituent mass in soil that represents an ongoing source to groundwater.

This TNT RAWP focuses specifically on the soil remedy, outlining a remedy for target constituents in soil compliant with New Jersey Administrative Code (N.J.A.C.) 7:26E – New Jersey Department of Environmental Protection's (NJDEP's) Technical Requirements for Site Remediation (TRSR) and protective of human health and the environment. The results of previous environmental investigations, and pre-design, treatability, and pilot studies presented herein, as well as academic research, establish the technical foundation and basis for the remedy.

1.1 Remedy Overview & Objectives

The RI identified target constituents in soil as a result of various historical manufacturing and operational processes and process upsets. The conceptual site model for target constituents in the TNT Project Area, as established in the Phase II RIR, identifies mass transfer from solid phase source material (primarily crystalline TNT) in soil as a source to groundwater, and biological degradation of target constituents as a natural process occurring in both soil and groundwater at the Facility. Acknowledging the influence of these natural degradation processes on target constituent concentrations, Hercules studied the feasibility and effectiveness of enhanced bioremediation as a remedy for target constituents in TNT Project Area soil. Study results informed the design of a multi-phase process focused on degrading source mass in soil to mitigate ongoing impacts to underlying groundwater at the Facility.

[4] For the purpose of this TNT RAWP, TNT, 2,4-DNT, 2,6-DNT, 2ADNT and 4ADNT are collectively referred to as "target constituents"

The multi-phased remedy involves three primary processes with the following objectives:

- Soil processing (i.e., excavation, blending, and processing in a soil processing plant) to make target constituent source mass present in crystalline forms accessible and amenable to bioremediation (increased surface area-to-volume ratio)
- Ex-situ enhanced bioremediation in constructed treatment cells (bio cells) to degrade target constituent mass (greater than 95 percent reduction in concentrations) over a short period of time (8 to 12 months) to at or less than their respective NJDEP NRDCSRS
- In-situ biodegradation addresses residual target constituent mass (over approximately 5 years) to facilitate corresponding target constituent concentration reductions in groundwater to support a future monitored natural attenuation groundwater remedy

The TNT Project Area will be included in a Facility-wide restrictive covenant (i.e., deed notice) established by Hercules that limits the Facility future uses to industrial/ commercial. This soil source mass remedy will address ongoing migration and influences on groundwater quality. Groundwater compliance and associated use restrictions will be addressed via a separate groundwater RAWP.

The following documents supported development of the remedial strategy in this TNT RAWP:

- *Site Investigation Report – Kenvil Works Facility* (SI; Hercules 2004)
- *Phase I Remedial Investigation Report – Kenvil Works Facility* (Phase I RIR; Hercules 2007)
- *Phase II Remedial Investigation Report – Kenvil Works Facility* (Phase II RIR; Hercules 2016)
- *Technical Memorandum – Evaluation of Alternatives for Separation of TNT from Soil* (Treatability Study; Hercules 2013)
- *TNT Bioremediation Pilot Study Report* (Pilot Study Report; Hercules 2017a)
- *TNT Soil Plant Design Verification Study Report* (Design Verification Study; Hercules 2017b)
- *TNT Bioremediation Design – Bio Cell Engineering & Stormwater Management Memorandum* (Design Support Memo; Hercules 2017c)
- *TNT Refined Delineation Work Plan* (TRDWP; Hercules 2017d)

The remainder of this TNT RAWP and its associated technical appendices present the remedial design and support the design with pre-remedial studies and investigation results. The implementation of the technical remedy is presented in the context of remedial action objectives and associated success criteria. Data collection to support remedy effectiveness relative to success criteria will occur under the monitoring programs presented herein.

1.2 Regulatory & Administrative Compliance

This TNT RAWP represents a component of ongoing environmental remediation activities at the Facility in fulfillment of a March 10, 1995 Remedial Agreement (RA) between the NJDEP and Hercules, and was prepared in accordance with N.J.A.C. 7:26E – NJDEP's TRSR, N.J.A.C. 7:26C

– NJDEP's *Administrative Requirements for the Remediation of Contaminated Sites* (ARRCS), and NJDEP's *Site Remediation Reform Act* (SRRA). The Facility is subject to the Remedial Investigation Statutory Timeframe established by the SRRA at New Jersey Statues Annotated (N.J.S.A.) 58:10C-27a(3). A two-year extension of the May 7, 2014 remedial investigation report submission deadline was granted in accordance with P.L. 2013, c.238 (N.J.S.A. 58:10C-27.1), extending the deadline to May 7, 2016. Hercules submitted the Phase II RIR on May 5, 2016 and continues to make progress toward designing and implementing remedies onsite and obtaining associated remedial action permits (RAPs).

This TNT RAWP was prepared in accordance with requirements established in N.J.A.C. 7:26E - 1.6 – NJDEP's Reporting Requirements, with variances from the cited regulation related to data presentation at N.J.A.C. 7:26E – 1.6(b)8.(3). The following subsections provide justification of data presentation elements that have deviated from the cited regulation (variances).

1.2.1 Data Presentation Variances

This TNT RAWP presents soil sample results collected subsequent to the submission of the Phase II RIR that supported remedial design. These data are presented in tables and depicted on a series of figures summarizing the TNT Project Area refined delineation sample results specific to individual constituents, as well as a group of constituents. Given the size of the TNT Project Area, sample density, and volume of data generated at each sample location, Facility-specific data presentation schemes were developed to provide a useful visual tool for the reader while fulfilling the fundamental intent of NJDEP's TRSR. Similar to the data presentation approach used in the Phase II RIR, the TNT RAWP figures present the following information:

- Property and former operational area boundaries and labels. Individual area of concern (AOC) (e.g., buildings) boundaries are illustrated but not labeled to reduce congestion and maintain readability at a meaningful scale.

- Individual sample locations labeled with location IDs. Sample IDs (location IDs appended with sample interval depth information) were omitted to reduce congestion and maintain readability at a meaningful scale.

- A pillar of stacked boxes, with each box corresponding to a depth interval. When sample data are available for the specified depth interval, the corresponding box is color-coded based on a comparison of the constituent concentration (or lowest constituent concentration when multiple samples were collected from the interval represented by the box) to comparison criteria (e.g., NJDEP's soil remediation standards). When sample data are not available, the box is populated with an "x". The intervals corresponding to each box remain consistent across constituent figures. This approach provides a visual representation of semi-quantitative constituent concentration ranges relative to comparison criteria and was used in lieu of posting constituent data on the figures. Corresponding constituent data is presented in data tables.

- Isopleth maps were included in the Phase II RIR based on a macroscale delineation. Refined delineation efforts in the TNT Project Area reduced the isopleths to individual excavation areas proposed in this TNT RAWP and depicted on the TNT RAWP figures.

This Facility-specific data presentation scheme is consistent with that used in the Phase II RIR and provides a useful visual tool for the reader while fulfilling the fundamental intent of NJDEP's TRSR.

1.3 Organization

The remainder of this TNT RAWP is organized as follows:

- Section 2, *Background*, describes the operational history and physical setting of the Facility and the TNT Project Area.
- Section 3, *Environmental Chronicle*, summarizes environmental investigation and cleanup activities conducted in the TNT Project Area.
- Section 4, *Remedy Development*, presents a remedial alternatives evaluation and feasibility and design studies for the selected remedy.
- Section 5, *TNT Project Area Soil Remedy,* describes the proposed remedy, implementation activities, long-term monitoring, and permitting requirements.
- Section 6, *Implementation Schedule*, presents the implementation schedule for the proposed remedial action.
- Section 7, *References*, presents full citations for materials supporting the preparation of the TNT RAWP.

A series of technical appendices and NJDEP forms supplement this TNT RAWP. Technical appendices include:

- Appendix A, *TNT Project Area Soil Ecological Risk Assessment* (TNT Project Area ERA), evaluates ecological risk under existing TNT Project Area conditions and identifies a group of constituents of potential ecological concern (COPECs) requiring additional evaluation following remedy implementation.
- Appendix B, *TNT Refined Delineation Technical Memorandum*, summarizes the methods and results of field sampling activities focused on refining the macroscale delineation of target constituents from the Phase II RIR.
- Appendix C, *TNT Project Area Soil Secondary COCs*, evaluates non-target constituents in the TNT Project Area and identifies constituents of concern (COCs) that merit consideration as part of TNT Project Area remediation.
- Appendix D, *TNT Bioremediation Process Confirmation Sampling Plan* (PCSP), presents a sampling plan to monitor the ex-situ bioremediation process and provide data to facilitate treated material reuse.
- Appendix E, *Facility-wide Quality Assurance Project Plan*, provides a single and concise plan for the collection and management of environmental data and the data quality objectives for the Facility. This document is not specific to the TNT Project Area and/or associated soil bioremediation remedy.

- Appendix F, *TNT Project Area Soil Reuse Plan*, documents compliance with NJDEP's *Fill Material Guidance for SRP Sites* (2015) to facilitate the use of treated material as backfill where biodegradation will continue in-situ.
- Appendix G, *TNT Project Area Excavation, Blending, and Staging Plan Construction Drawings*, presents a series of excavation plans based on boundaries identified during the refined delineation of target constituents.
- Appendix H, *Technical Performance Information – PeroxyChem's DARAMEND OE® and EHC®*, provides empirical data from previous studies and projects related to the performance of DARAMEND OE® and EHC® that supports elements of the TNT Project Area remedy.
- Appendix I, *Project Implementation Timeline*, outlines the timeframes for remaining design, permitting, construction and implementation activities.
- Appendix J, *Waste Determination*, documents the assessment of project material streams in the context of Resource Conservation and Recovery Act (RCRA).

NJDEP Forms include:

- Cover/Certification Form
- CID Worksheet
- Authorization to Submit the Remedial Action Work Plan through NJDEP Online

Tables, figures, forms, appendices, attachments, and supporting documents are referenced where appropriate throughout the text.

Section 2: Background

2.1 Facility Overview

The Facility occupies 1,059 acres along the Route 80 corridor and is located approximately 0.5 miles northwest of the center of Kenvil, in Morris County, New Jersey. Regionally, the Facility is approximately 40 miles west of New York City and 30 miles east of the Delaware Water Gap. The Facility is located in the New Jersey Highlands physiographic province of north-central New Jersey amidst the characteristic broad, elevated ridges separated by long, narrow valleys. The Facility is situated on a valley floor between two forested ridgelines oriented in a southwest to northeast direction. Beyond these forested ridgelines, the Facility is flanked by transit routes (I-80, New Jersey Transit railroad), state and county roads (Route 46, Berkshire Valley Road, Howard Boulevard), and a mixture of commercial and residential development.

The Facility began operation in 1871, initially manufacturing dynamite to support the regional iron ore mining industry. The Facility was operated by various companies until 1912, when Hercules became the sole owner. Throughout its history, the Facility manufactured propellants and explosive and energetic (E&E) constituents such as TNT, nitroglycerin (NG), pentaerythritol tetranitrate (PETN), smokeless powder, ammonium nitrate fuel oil (ANFO), and various specialty products (e.g., initiating materials, ingredients for medical applications, and materials for actuating devices) for military and commercial applications. Through the latter years of Facility operation, production focused mainly on smokeless powders. Alliant Tech Systems produced smokeless powder under a Facility lease agreement from 1995 to 1996. The Facility ceased operation in December 1996, and Hercules re-acquired control of the Facility on January 1, 1997.

Approximately 800 acres of the Facility supported former manufacturing operations. The remaining acreage existed as an undeveloped buffer between former active manufacturing areas of the Facility and/or the surrounding community. The former Facility operational areas (**Figure 2**) remain vacant following decommissioning and demolition activities conducted between 1996 and 2003. The former TNT, PETN, and Dynamite manufacturing areas, and the TNT Project Area, are located in the southwestern corner of the Facility along the eastern slope of the western ridgeline and on the relatively flat valley floor to the east (**Figure 3**).

2.2 TNT Project Area

2.2.1 Description & History

The Facility produced TNT from 1917 until 1919, after which time the production area remained dormant until demolition in the early 1970s. Site investigation and remedial investigation (SI/RI) activities identified TNT, intermediary manufacturing products (e.g., 2,4-DNT) and degradation byproducts in soil and groundwater within areas that historically supported TNT manufacturing.

TNT production occurred as a batch process, and involved 38 separate storage, filter, processing, and manufacturing houses located throughout the TNT Project Area. Collectively, these structures made up the TNT production lines. In general, manufacturing (e.g., nitration) occurred in the area along the slope of the western ridge, while finishing (e.g., drying, pressing, packing, storage) and

ancillary functions (e.g., process liquid and spent acid recovery) occurred in structures to the south and east on the valley floor.

Processing and movement of raw materials, intermediaries, and finished product through the TNT line provided opportunities for the release of manufacturing-related constituents[5] to the Facility soil, as did process upsets (e.g., fires, explosions). At room temperature, both TNT and DNT occur as crystalline solids. When released to the ground during manufacturing process upsets, these materials were in a heated liquid form and capable of migrating short distances in soil before solidifying. Subsequent distribution, migration, and degradation has occurred over the last century, resulting in the presence of target constituents in soil and groundwater underlying the TNT Project Area. The presence of ADNTs[6] provides an indication that microbial (biological) degradation of TNT is naturally occurring in Facility soil and groundwater.

2.2.2 Geology & Hydrogeology

The TNT Project Area occupies approximately 80 acres that spans the eastern slope and terminus of the western ridge and a portion of the adjacent valley floor. Ground surface elevations range from 720 to 800 feet above mean sea level.

Soil types vary between the ridge and valley. Ridge soils are comprised of colluvium and weathered bedrock while valley floor soils are predominantly sand and gravel, with minimal to moderate silt and clay. Bedrock underlies the ridge at depths ranging from 10 to 50 feet, and dips to approximately 200 feet below ground surface (ft bgs) in the valley.

The unconfined upper valley fill aquifer underlies the TNT Project Area. Water table elevations generally follow the ground surface topography, with depth to water on the ridge averaging 20 ft bgs tapering to within a few feet of ground surface on the valley floor.

2.2.3 Ecology and Land Use

Former operational structures have been demolished in the TNT Project Area. The area currently exists as vacant land in various states of vegetative succession, primarily grass field and shrublands, interspersed with remnant building remains (e.g., concrete rubble piles) and ground surface infrastructure (e.g., unimproved roads, drainage ditches).

The upper slope of the western ridge immediately west of the TNT Project Area is a mature hardwood forest with sparse understory, and formerly functioned as a buffer between the Facility and surrounding community. Howard Boulevard, commercial development, and an undeveloped steep, terraced ridge occur immediately west of the TNT Project Area. An expansive wetland mosaic punctuated with upland areas constructed to support former operational structures or transportation corridors (railbeds and roads) lies to the east of the TNT Project Area.

[5] Target constituents represent the primary manufacturing-related constituents in the TNT Project Area. Lead-lined process vessels and piping were used in the TNT manufacturing process, and lead represents a secondary manufacturing-related constituent on the TNT Project Area.
[6] Collective term that includes 2-ADNT and 4-ADNT

Section 3: Environmental Chronicle

3.1 Overview

As part of the RA executed between Hercules and NJDEP in March 1995, a Facility-wide strategy was developed to guide the investigation, remediation, and closure of the Facility. The strategy employs a phased approach whereby the focus of subsequent phases is tailored based on interpretation of information obtained during previous phase(s). The strategic approach considers both areal extent (i.e., entire Facility, former operational areas, individual features) and media of interest (i.e., soil, groundwater, surface water, sediment) as appropriate.

A 1993 Preliminary Assessment (PA) of the Facility provided background information for the Facility and identified areas of potential concern. Upon cessation of operations at the Facility at the end of 1996, Hercules initiated the SI process, and reviewed the PA to develop the scope of the SI. The SI provided an initial Facility-wide characterization of environmental media based on soil (~1,900), groundwater (157), sediment (157), and surface water (120) samples. Ultimately the results of the SI sampling and analyses were used to develop the scope, sampling locations, and analytical suite for the Phase I RI. The SI identified areas of former operational influence within the TNT Project Area and reserved them for investigation as part of the RI.

Considering the SI results, and acknowledging the manufacturing processes, environmental influences, and constituents of concern common to each former manufacturing (operational) area at the Facility, the RI investigation strategy aggregated individual operational features (designated as AOCs in the SI) into 13 major AOCs that generally corresponded to former operational areas of the Facility. This investigation strategy aligned with the scale of the Facility and widespread use of batch processes[7] to produce E&E products, geographic segregation of production lines, and is commensurate with the scale at which remedies would be designed and implemented.

Building on the SI results, the Phase I RI sampling provided spatial coverage (grid sampling), additional sampling at select features (i.e., those requiring additional investigation after the SI or reserved entirely for the RI), and macroscale delineation at the major AOC and/or Facility boundaries. The Phase I RI defined the nature and extent of constituents present at concentrations exceeding applicable media-specific comparison criteria. The Phase II RI focused on filling data gaps and completing characterization of soil, sediment, surface water, and groundwater conditions onsite. The Phase II RIR presented a Case Inventory Document (CID) tracking 13 upland soil AOCs onsite based on the former operational area boundaries (**Figure 2**) and 3 AOCs based on other environmental media investigated onsite (e.g., groundwater, surface water, sediment), and a separate table tracking each of the ~1,200 AOCs identified during the SI. The Phase II RIR also included an ecological risk assessment.

Collectively, the SI/RI characterized and delineated the nature and extent of Facility-related influences and evaluated potential ecological risks. The cumulative findings of these investigations informed the development of a conceptual site model (CSM) and provide a sound foundation on which to base remedial decision making.

[7] The batch processes relied on a series of small houses (structures) where individual steps in the manufacturing process would occur. For example, TNT production occurred as a batch process involving 38 separate storage, filter, processing, and manufacturing houses located throughout the TNT Project Area. Collectively, these structures made up the TNT production lines.

3.2 TNT Project Area

3.2.1 Area of Concern

As discussed in Section 3.1, the environmental investigation strategy evolved as the SI/RI progressed to align with the scale at which Facility-related environmental influences and remediation will occur (e.g., across production areas formerly occupied by a series of manufacturing structures). Consistent with this approach, this RAWP defines the TNT Project Area as the AOC. This AOC contains the former TNT manufacturing line (38 unique structures) and associated drying, finishing, packing, and storage structures that supported TNT manufacturing operations.

The proposed remedy for this AOC achieves remedial action objectives for a contiguous geographic area with common constituents of concern attributable to a discrete historical operation at the Facility. For the purposes of administrative tracking, the TNT Project Area contains the former TNT operational area (AOC-11) and portions of the Dynamite (AOC-5), NG (AOC-9), and PETN (AOC-13) operational areas and the 108 unique features identified as individual AOCs during the SI. **Table 1** presents an updated CID illustrating the change in remedial phase to these areas. The CID has been submitted via NJDEP's online portal as part of submission of this TNT RAWP. **Table 2** provides a list of the individual features identified within the TNT Project Area.

3.2.2 SI/RI

SI planning efforts identified AOCs using a focused, infrastructure-driven approach (e.g., each building and process vessel was designated as its own AOC) consistent with NJDEP regulatory requirements at the time (circa 1998). During SI data evaluation, the information gathered from these AOCs indicated that groups of AOCs located in proximity to each other and supporting a single operation (e.g., TNT manufacturing) shared common practices, processes, and Facility-related influences. In areas of the Facility where former operations occupied a large footprint without substantial buffers or boundaries, delineation of AOCs proved problematic due to the extensive areas across which Facility-related influences exist.

Therefore, the RI strategy was modified to focus on defining the nature and extent of Facility-related COCs while accounting for individual AOCs requiring further investigation. AOC groups were developed based on geographic and process-related commonalities. This consolidated AOC approach met the intent of the applicable NJDEP regulations, to define the nature and extent of constituents present at concentrations exceeding a standard, Facility-wide. The approach leveraged findings of successive investigations to achieve a characterization and delineation that is both comprehensive and informative in the context of identification of areas in need of remediation.

The approach used throughout the RI contributed to defining the TNT Project Area presented in this TNT RAWP. Remedial planning has refined the characterization of the nature and extent of target constituents provided by the RI (Section 3.2.4) to inform remedial design (e.g., excavation planning).

3.2.3 Ecological Risk Assessment

The *Ecological Evaluation/Ecological Risk Assessment* (EE/ERA) submitted as part of the Phase II RIR identified several areas within the Remedial Area where remedial action is warranted irrespective of the outcome of the ERA. These "areas of presumed remedial action" were identified based on a review of the CSM, historical Facility information, and the SI/RI data; and ERA activities were to be incorporated into the remedial design to ensure that the proposed remedy for each area remained protective of ecological receptors.

An area of similar location and areal extent to the TNT Project Area was designated an area of presumed remedial action in the EE/ERA. As part of TNT RAWP preparation, an ERA was conducted using the TNT Project Area dataset to confirm that the proposed remedial design is protective of ecological receptors. The ERA was conducted consistent with the screening process outlined in the EE/ERA.

The TNT Project Area ERA (**Appendix A**) identifies the following:

- Potential unacceptable ecological risks attributable to E&E constituents and metals under existing (pre-remediation) conditions
- Acceptable potential risk estimates for target constituents (and E&E constituents in general) under post-remediation conditions, including the interim remedial condition immediately following excavation backfilling and prior to ongoing in-situ degradation of target constituents
- Consistent results (i.e., acceptable potential risk estimates) for E&E constituents under post-remediation conditions evaluated using ecological screening benchmarks released following preparation of the EE/ERA

Based on these results, the proposed remedy is protective of ecological receptors exposed to target constituents in TNT Project Area soil.

A suite of comingled metals drives unacceptable risk estimates based on pre-remediation conditions in the TNT Project Area. Remedy implementation will alter the nature and extent of comingled metals in soil and associated exposure conditions. As such, these constituents will be re-evaluated to assess potential exposures and risks following remedy implementation.

3.2.4 Refined Delineation

The SI/RI applied a macroscale approach to delineating TNT and its breakdown products in the TNT Project Area. Refined delineation sampling, as outlined in the TRDWP (Hercules 2017d), built upon the understanding of nature and extent of target constituents identified by the SI/RI with the purpose of more accurately defining the volume of soil requiring ex-situ treatment to remediate target constituents, and provide additional characterization data to support remedial planning (i.e., excavation planning, material handling, and regulatory compliance).

Refined delineation activities included:

- Excavating and screening 180 test pits within the TNT Project Area
- Collecting 565 soil samples
- Analyzing 486 soil samples for Nitroaromatics and Nitramines via United States Environmental Protection Agency SW-846 Method 8095
- Delineating 22 discrete areas with target constituent concentrations greater than their respective impact to groundwater soil remediation standards (IGWSRS) in the TNT Project Area

Appendix B presents a summary of refined delineation activities and sampling results.

Based on these efforts, a combined dataset totaling over 400 samples from the TNT Project Area (i.e., refined delineation and SI/RI data) supports remedial design and remedy implementation (e.g., excavation extents and sequencing).

As noted, refined delineation activities focused on areas within the TNT Project Area. The SI/RI identified isolated detections of target constituents at concentrations greater than NJDEP NRDCSRS beyond the TNT Project Area. Hercules acknowledges that these isolated, discrete areas may represent additional source mass, and is evaluating these areas to identify those that require further investigation to refine the nature and extent. The results of this evaluation will be summarized in a work plan that identifies data gaps and establishes a sampling plan. Data generated during this refined delineation event will be evaluated to identify appropriate remedial options.

3.3 Nature & Extent

The comprehensive TNT Project Area dataset delineates the nature and extent of target constituents to the most stringent of the NJDEP's default IGWSRS, residential direct contact soil remediation standards (RDCSRS), and NRDCSRS (**Appendix B**).

For this TNT RAWP, COCs are assessed as follows:

- *Primary COCs:* target constituents (TNT, 2,4-DNT, 2,6-DNT, 2ADNT, 4ADNT) that the proposed remedy is designed to remediate via biological degradation
- *Secondary/Comingled COCs:* constituents other than target constituents (i.e., nitroglycerin, nitrobenzene, 1,3-dinitrobenzene, arsenic, copper, lead, mercury, and nickel) that also merit remediation per NJDEP's TRSR and *Technical Guidance for the Attainment of Remediation Standards and Site-Specific Criteria* (Attainment Guidance) (2012)

The following sections address each group of COCs.

3.3.1 Constituents of Concern

3.3.1.1 Primary

This TNT RAWP presents a remedial design for a proposed remedy addressing target constituents; as these constituent, TNT in particular, are the most prevalent with respect to magnitude and extent in TNT Project Area soil and also present in underlying groundwater. The remedy has been developed to specifically degrade target constituents. Design studies have also assessed the presence of comingled constituents (secondary) and associated influences of soil preparation and bioremediation processes.

3.3.1.2 Secondary/Comingled

Hercules evaluated the comprehensive TNT Project Area dataset to identify constituents other than target constituents that, while less prevalent, also require remediation per NJDEP's TRSR. In brief, the evaluation stepped through the hierarchical process outlined in NJDEP's Attainment Guidance, using a combination of point-by-point comparisons, statistical evaluations (i.e., 95 percent upper confidence limit of the mean [95UCL]), and spatial weighting using Theisen polygons to identify constituents requiring remediation per NJDEP's TRSR. The evaluation assessed impact to groundwater and direct contact pathways, with the direct contact evaluation relying on NJDEP's NRDCSRS based on the future use of the Facility restricted to commercial/industrial. **Appendix C** presents the methods and results of the compliance evaluation.

Compliance evaluation results indicate the following:

- The TNT Project Area requires 29 functional areas to evaluate direct contact compliance and 23 functional areas to evaluate impact to groundwater compliance

- The direct contact compliance evaluation identified nitroglycerin, arsenic, and lead in the shallow (0 to 2 ft bgs) interval in multiple functional areas at spatially weighted concentrations greater than their respective NRDCSRS

- The impact to groundwater compliance evaluation identified seven constituents (1,3-dinitrobenzene, nitrobenzene, and five metals[8]) in shallow (greater than 2 ft above the water table) and deep (within 2 ft of the water table) intervals across 14 functional areas at spatially-weighted concentrations greater than their respective IGWSRS

- An evaluation of lead results for the impact to groundwater pathway in the context of NJDEP's Guidance for the Evaluation of Immobile Chemicals for the Impact to Groundwater Pathway (2008) reduced the number of shallow intervals in functional areas in which lead is retained as a secondary COC

Based on the compliance evaluation, the following constituents are retained as COCs that merit remedial action in at least one functional area within the TNT Project Area:

- *E&E:* nitroglycerin, 1,3-dinitrobenzene, and nitrobenzene

[8] Metals include arsenic, copper, lead, mercury, and nickel.

- *Metals:* arsenic, copper, lead, mercury, and nickel

E&E constituents are comingled with target constituents and will be addressed via the proposed remedy, as enhanced biodegradation using DARAMEND OE® has shown to be an effective remedial strategy for these organic constituents (**Appendix H**).

Metals occur both within and beyond excavation areas defined by target constituent concentrations. Samples at five locations within excavation areas contain lead and/or arsenic at concentrations exceeding their NJDEP NRDCSRS. Soil removed from the portion of the excavation area represented by these five samples will be segregated during processing and treatment, and returned to the excavation from which they were removed. Process confirmation and long-term monitoring sampling will assess the distribution of lead and arsenic following processing, and during both ex-situ and in-situ treatment. Remaining samples occurring beyond the excavation boundaries will be evaluated during final design such that grading activities do not redistribute constituents. If regrading is necessary in these areas, the grading plan will address the tracking of soil from these areas and post-remedy sampling will characterize disturbed areas. The need for additional remedial activities to address metals COCs will addressed once excavations are backfilled prior to initiating site restoration activities.

Appendix C provides additional information regarding the sample location(s) contributing to these results, their coincidence with areas to be disturbed (e.g., excavated or otherwise altered via grading or infrastructure improvement) during remedy implementation, and strategies to address them in support of TNT Project Area closure.

Section 4: Remedy Development

Hercules identified the need for active remediation of target constituents in the TNT Project Area early in the SI/RI process. Acknowledging the conditions in the TNT Project Area, Hercules initiated a series of studies in cooperation with academic and industry partners to assess Facility-specific soil and groundwater conditions, and their influence on microbial degradation pathways. These initial efforts led to a series of focused evaluations and studies to define, select, and refine the remedy outlined in Section 5. The remainder of this section summarizes remedial selection and design activities, including:

- An alternatives evaluation to assess remedial technologies and options
- Bench-scale treatability studies to evaluate the effectiveness of select alternatives
- Conceptual bioremediation design to develop a phased treatment approach
- A pilot study to test the effectiveness of the bioremediation design at field scale

Based on the outcome of these processes, Hercules initiated remedial design activities, and reviewed and refined the remedy based on technical reviews and interaction with NJDEP SRP feedback.

4.1 Alternatives Evaluation

Hercules' initial studies related to TNT and its breakdown products identified native microbial communities in soil and groundwater at the Facility degrading constituent mass. These studies identified source mass reduction in soil as a critical element of a comprehensive TNT Project Area remedy reliant upon biodegradation (e.g., monitored natural attenuation) to address residual mass in soil and groundwater.

TNT source mass in soil exists as crystalline solid TNT nodules heterogeneously entrained in the soil matrix. Hercules recognized that the presence of a solid within a solid matrix would be a critical factor in developing an effective remedy. A survey of publicly available literature, case studies, and regulatory documents was used to identify remedial technologies potentially applicable to TNT and the Facility setting.

The survey identified the following technology types and approaches for consideration:

- Excavation and Offsite Disposal
- In-situ Stabilization
- Ex-situ Thermal Treatment
- Ex-situ Composting (Biofarming)
- Ex-situ Physical and Density Separation

Based on a comparative analysis of effectiveness, cost, and feasibility, ex-situ physical and density separation was thought to provide a scalable, cost-effective solution to meet treatment objectives. Literature and ongoing biodegradation research by academic and industry partners

indicates that this method effectively minimizes the number and volume of waste streams requiring offsite disposal and recognizes the benefits of natural biodegradation of TNT[9] occurring onsite.

Attachment 1 presents Hercules' February 22, 2013 technical memorandum summarizing the alternatives evaluation and a conceptual physical and density separation approach.

4.2 Feasibility & Design Studies

A series of bench-scale studies were used to evaluate the ex-situ physical and density separation approach identified during the alternatives analysis (**Attachment 1**), identify process improvements, and develop the conceptual remedy that led to the remedial design presented in Section 5.

The stepwise process of testing and refining the technical approach occurred through a series of studies outlined in the following subsections.

4.2.1 Treatability Study

In follow-up to identifying physical and density separation as a potential component of the remedy for TNT in soil at the Facility, Hercules' conducted a treatability study to assess the feasibility of removing the crystalline TNT from Facility soils, and if feasible, evaluate potential remedial options for the remaining soil fraction(s). This study focused on multiple physical separation processes to develop a treatment process capable of achieving an 85 percent reduction in TNT mass. The 85 percent mass removal target was derived from some early academic studies performed on behalf of Hercules and assumed that the remaining 15 percent mass exists as residuals that are accessible for natural microbial degradation.

The study results, presented in **Attachment 2**, indicated that physical separation processes effectively:

- Segregated soil particles by grain size
- Facilitated removal of large crystalline TNT particles from gravel and larger sized soils (i.e., grain size greater than 2 mm in diameter)
- Concentrated residual energetic material in the finer grained fractions (grain size less than 2 mm in diameter)

The physical separation process generated a TNT concentrate waste stream requiring management and offsite disposal via thermal destruction. With the knowledge that physical processes alone could not achieve NJDEP soil remediation standards (SRS), and that offsite destruction would be very costly, the treatability study went on to evaluate chemical oxidation using Fenton's reagent to reduce concentrations of TNT and its breakdown products. Based on these findings, a series of back-end treatment concepts were developed to address the TNT mass in finer grain size fractions.

[9] Facility-specific studies indicate that the natural degradation process plateaus at formation of ADNTs and requires external stimulation or unreasonably long timeframes to achieve complete degradation to humic/fatty acids.

These options included:

- *Physical Separation*: including oversize grinding and treatment using attrition and flotation – requires additional treatment of sand and fines fractions

- *Physical Separation with Chemical Oxidation for sand fraction*: demonstrated to reduce target constituent concentrations below NJDEP NRDCSRS – requires additional treatment of fines fraction

- *Physical Separation with Chemical Oxidation for sand and fines fractions*: no additional treatment required to achieve target constituent NJDEP NRDCSRS

While chemical oxidation achieved the stated objectives at bench scale, further evaluation identified the following challenges associated with full-scale field implementation:

- Chemical oxidation would consume a substantial quantity of bulk chemicals (i.e., concentrated hydrogen peroxide), requiring an extensive regulatory permitting effort to authorize their storage and use at the Facility.

- Reagent contact occurred in a soil slurry (~15 percent solids), yielding a large volume of water requiring offsite disposal or additional onsite treatment.

Ultimately, treatability study results demonstrated that:

- Physical separation of TNT from soil yields a TNT concentrate waste stream that is costly to manage and dispose

- Supplemental chemical treatment to achieve NJDEP NRDCSRS is resource intensive and requires regulatory permits

Based on the findings of the treatability study, Hercules opted to further investigate bioremediation as a means of enhancing the natural degradation of TNT in soil. Bioremediation is an established remedial technology and has been used by the US Department of Defense (DoD) on a number of TNT remediation projects (i.e., Raritan Arsenal [NJ], Tooele Army Ammunition Depot [UT], Yorktown Naval Weapons Station [VA], Iowa Army Ammunition Plant [IA]) (**Appendix H**). A variety of techniques can be used to achieve and maintain soil conditions that facilitate bioremediation; land farming and/or composting represent low-tech options that require higher ratios of organic amendment in soil, while commercially-formulated mixtures enhance specific reactions in a low-bulking approach.

4.2.2 Bioremediation Conceptual Approach

Prior to the exploration of bioremediation, and specifically the evaluation of commercially-available amendments, conceptual remedies included two general steps – remove TNT nodules from soil and dispose of them offsite via incineration, and treat the residual mass in soil. The use of commercially available amendments to enhance biological degradation resulted in an evolutionary change to this two-step process. Specifically, rather than physically separating TNT nodules from soil, the soil would undergo a physical preparation process to reduce TNT particle size. Reducing the TNT particle size enhances the effectiveness of bioremediation and reduces

the time necessary to degrade the mass. This approach also eliminates the TNT concentrate waste stream, destroying mass onsite rather than moving mass offsite.

A two-step conceptual bioremediation remedy evolved to include physical preparation (grain size reduction, large aggregate removal) followed by bioremediation via a commercially available amendment.

To evaluate the feasibility and effectiveness of this conceptual approach, Hercules conducted a proof of concept pilot study using approaches scalable to full-scale implementation.

4.2.3 Pilot Study

The TNT bioremediation pilot study explored enhanced biodegradation techniques and assessed the influence of three key variables: amendment type, amendment dose, and dosing regime (incremental vs. one time). Pilot study activities began in spring 2015.

Pilot study activities occurred in two phases:

- *Phase I – Soil Preparation*: soil processing to generate the less than 2mm soil fraction containing TNT mass

- *Phase II – Management and Monitoring*: 84-day study period consisted of six 14-day cycles, weekly in-situ monitoring and moisture management, and bi-weekly analytical sampling

Attachment 3 presents the *TNT Bioremediation Pilot Study Report* summarizing pilot study procedures and monitoring results. **Attachment 4** presents a technical memorandum summarizing the results of supplemental post-study monitoring of pilot study soil that documents ongoing incremental reductions in target constituent concentrations following the initial study period. Collectively these documents present the results of the 84-day pilot study period during which active management of the soil occurred, and four monitoring events spanning the two years following the active management study period.

The results presented in these documents indicate that:

- TNT degradation occurs naturally in Facility soil, as demonstrated by the production of ADNTs during the study period in control trials. NJDEP SRS (NRDCSRS and RDCSRS) were not achieved in the control trials.

- Wood mulch composting using a low-bulking approach demonstrated an ability to degrade TNT. However, the trials did not achieve NJDEP SRS for target constituents during the study period.

- DARAMEND OE®, the commercially available amendment evaluated in the study, achieved NJDEP SRS for target constituents within the study period. The amendment dose and dosing regime influenced the amount of time needed to achieve these standards.

- Biodegradation of target constituents in soil in DARAMEND OE® trials continues to occur following active management.

Overall, the pilot study demonstrated that bioremediation using a commercially available amendment is a viable mass reduction component of a comprehensive remedy for target constituents in the TNT Project Area. Residual constituent mass (i.e., concentrations greater than IGWSSLs) will be addressed via the lasting effects of the amendment in soil (i.e., DARAMEND OE® continues to support biological breakdown for approximately 5 years) (**Appendix H**). Natural attenuation by native microbial communities will continue following the effective timeframe of DARAMEND OE® and will be the final remedy for soil and groundwater.

The pilot study also called attention to several additional considerations at full-scale implementation, beyond the effectiveness and efficiency of DARAMEND OE®. Considerations included:

- *Material handling and management:* The slurried feed material reduces mechanical handling effort and may prove to be an efficient means of transporting material from the processing area to the soil treatment cell.

- *Material processing*: Amendment distribution and feed material homogeneity are critical aspects of achieving expected results at full-scale. The heterogeneous mixture achieved in the pilot study via mechanical mixing was effective; however, improvements can be made at full scale that would result in more homogenous blending.

- *Non-target constituents*: Treatability and pilot work focused primarily on target constituents. The pilot study included a cursory evaluation of the fate of comingled non-target constituents (e.g., lead and pyrogenic polycyclic aromatic hydrocarbons). Remedial design should address soil containing non-target constituents exceeding NJDEP remedial standards and its potential effect on reuse of treated material to the excavation area.

4.2.4 Conceptual Process Design

Based on the results of the pilot study, Hercules initiated a conceptual process design for full-scale remediation of target constituents in TNT Project Area soil. The conceptual design included the following components:

- Particle size reduction and segregation of oversize aggregate using a physical soil processing plant to create biofeed

- Amendment of biofeed with DARAMEND OE®

- Delivery of amended biofeed to bio cells for engineered bioremediation

The design process identified several estimates and input parameters requiring confirmation to support process plant design and engineering. A series of field-based design verification studies refined estimates and design input parameters. **Attachment 5** presents the *TNT Soil Plant Design Verification Study Report* summarizing the findings of these studies.

Collectively, the initial design and supplemental verification study results were used to develop a preliminary design drawings package (**Attachment 6**). These drawings illustrate the process plant design and conceptual layout in the TNT Project Area. Actual plant process components and size,

location, and configuration of supporting structures (e.g., bio cells) will be identified during final design and engineering.

4.2.5 Water Budget & Engineering Evaluation

4.2.5.1 Water Budget

The bioremediation remedy outlined in the conceptual process design (Section 4.2.4) and more fully developed in Section 5 requires water to facilitate aggregate separation and grain size reduction, as well as to maintain optimal conditions for biological degradation in the bio cells. A water budget was developed to assist in the planning, design, and engineering of water supply and management systems associated with the process design.

The water budget considers the following:

- Process water managed via a closed loop system
- Makeup water originates from captured precipitation and/or the Facility's potable water supply
- Annual implementation occurring in cycles, with active and passive periods of the year
- Accumulated precipitation and associated stormwater runoff (i.e., plant process pad, water management basin, bio cells) represents a major contributory source of water requiring management
- Stormwater management strategies involve both capture and contain (for water potentially in contact with contaminants) and non-contact runoff. To the extent practicable, covering structures and surfaces will be considered to increase the fraction of stormwater managed as non-contact runoff
- Extreme (i.e., 100-year storm) precipitation events at various times throughout the duration of remedy implementation
- Local, state, and federal water management regulations, guidance, and best management practices.

Water management planning, including process demands, recycle rates, stormwater calculations, water storage basin engineering, and contingency planning, will be completed as part of final design.

4.2.5.2 Engineering Evaluation

The conceptual process design illustrates slurried amended biofeed delivered to bio cells for engineered bioremediation. The conceptual bio cell design considers use of conventional concrete bin blocks stacked three high to form the structural element of the bio cell (**Attachment 6**). The bio cell will be lined with high-density polyethylene (HDPE) liner material with leak detection capabilities. As it is pumped to the bio cells, the slurried amended biofeed will be mixed with a polymer to facilitate coagulation and dewatering.

A basic stability assessment evaluated the potential for sliding and overturning of the concrete bin block wall configuration of the bio cells. Assessment results indicated that sliding was possible, but unlikely (within the applied safety factor). Final design will consider methods to increase the

factor of safety, including passive soil placement along the outside of the concrete bin block system or "keying" the bin block system below the ground surface to provide added lateral stability, as well as the use of geotextile bags (e.g., geotubes) within the bio cell to alleviate lateral pressures. Analyses of potential settlement due to bio cell loading indicated that excessive settlement was not an issue.

4.3 Independent Technical Review

In 2017, Hercules compiled pilot study and conceptual design information and presented it to an independent technical review group consisting of industry peers, consultants, and other technical experts. The technical review involved a critical look at the conceptual design and identification of potential blind spots, design flaws, and/or value engineering opportunities. The review highlighted certain previously identified considerations (i.e., water management) as critical aspects of design, and demonstrated that the work to date was a suitable foundation on which to base the engineering design.

4.4 December 5, 2018 NJDEP Meeting

Following the successful technical review in 2017, Hercules collected field samples and evaluated analytical results in support of developing a TNT Project Area-specific impact to groundwater soil remediation standard (IGWSRS) in 2018. The synthetic precipitate leachate procedure (SPLP) dataset used in the evaluation had a high degree of variability, and presented challenges when following methods established in NJDEP's *Development of Site-Specific IGWSRS Using the SPLP* (2013). In response, Hercules requested a technical consultation with NJDEP.

Representatives from Hercules and NJDEP met in December 2018 to build consensus on the technical scope, regulatory approach, and site-specific cleanup goals associated with the proposed TNT Project Area remedy. Hercules provided an overview of the proposed remedy that included a summary of academic research, treatability studies, and field pilot studies that yielded Facility-specific data relative to the biodegradation of TNT and its metabolites. This data provided the technical basis for the proposed remedies for soil and groundwater.

NJDEP understood Hercules' proactive effort to address the impact to groundwater pathway and remediation standard and indicated that the involvement of their IGWSRS technical staff may be premature given where the project is in the remedial process. NJDEP also noted the reduced reliance on a site-specific IGWSRS in instances where groundwater contamination already exists, such as this case. The parties agreed that the study results to date justify the proposed remedy and are sufficient to support development of this TNT RAWP.

As per NJDEP guidance, Hercules will consult with NJDEP regarding development of a post-remediation site-specific impact to groundwater standard following active remediation of soil and monitoring of concentration trends in groundwater.

Attachment 7 presents the meeting minutes and NJDEP's acknowledgement from the December 5, 2018 meeting.

4.5 Regulated Waste Evaluation

Given the specific nature of wastes generated during the manufacturing of explosives, the USEPA has assigned K-series listing codes to certain waste materials related to the manufacturing of TNT. Specifically, these include:

- K044 - Wastewater treatment sludges from the manufacturing and processing of explosives
- K045 - Spent carbon from the treatment of wastewaters containing explosives
- K047 - Pink/red water from TNT operations

Hercules conducted an evaluation of the remedy in the context of these hazardous waste listing categories to identify potentially applicable regulations and permitting requirements. The evaluation identified that none of the three listing categories applied to the proposed remediation, based on the fact that the materials being remediated are neither wastewater treatment sludges, spent carbon, nor pink/red water from TNT operations. Hercules confirmed the results of their evaluation and obtained a formal waste classification from NJDEP in cooperation with NJDEP's RCRA Coordinator (**Appendix J**).

4.6 Sustainability

TNT Project Area remedial design considered socioeconomic, quality of life, and environmental influences of the project. These project considerations fall within the broader category of sustainable and/or green remediation. Recognizing that the surrounding community and environment as a whole are stakeholders in this process, Hercules evaluated guidance on sustainable remediation and associated best management practices published by a number of entities during the remedial design process, including:

- USEPA Region 2 Clean and Green Policy
- USEPA's Principles for Greener Cleanups
- Interstate Technology and Regulatory Council's Green and Sustainable Remediation guidance
- Sustainable Remediation Forum's resource library

The following list illustrates project elements designed to incorporate and/or aligned with sustainable remediation practices.

Resource Conservation

Energy – bioremediation onsite avoids fossil fuel consumption associated with offsite transportation (diesel) and thermal destruction (natural gas). Further, the reliance on utility-provided electricity to operate the plant in lieu of a diesel generator reduces net energy consumption. A diesel generator would rely solely on fossil fuels while the power provided from the electric grid is generated, in part, via renewable sources (i.e., wind, solar, pumped storage). FirstEnergy, the parent company of Jersey Central Power & Light that distributes

electricity at the Facility, generates more than 1/3 of its power from carbon-free sources. Contractors bidding on project implementation will be encouraged to use modern equipment with clean diesel technologies to further reduce the project's carbon footprint.

Water – the plant operates on a closed, recycled water loop. Captured stormwater serves as a source of make-up water and reduces the potable water make-up demand. The recycled process water serves as a source of irrigation water to maintain target soil moisture content in the bio cells. This closed loop system supplemented with stormwater will reduce the demand from the local aquifer by more than 5 million gallons over the course of the project.

Material Reuse – treated material will be used as backfill, eliminating the need for imported clean material to bring excavated areas to grade. Aggregate brought onsite to construct pads and roads will be removed at the end of the project, washed in the soil processing plant (with modifications) and certified for reuse elsewhere onsite.

Reliance on Natural Processes – the remedy leverages the natural microbial degradation of E&E in Facility soil that has been occurring for more than 100 years. The physical processing of the soil and addition of DARAMEND OE® simply optimize this ongoing natural process.

Land Reuse – the use of treated soil as backfill in excavated areas, and ongoing degradation of residual mass, facilitates reuse of the former TNT area for commercial/industrial uses. The remediation aligns with the overall Facility redevelopment plan focused on brownfields-type reuse of former industrial areas of the property.

Mass Destruction – bioremediation destroys target constituent mass, avoiding the physical transfer of mass from one location (the Facility) to another (a landfill) and eliminating a future environmental liability.

Community – the management and remediation of materials onsite reduce the heavy truck traffic in the surrounding community that would be necessary if material was excavated and sent offsite for treatment. Work will be conducted during normal working hours by a relatively small crew, avoiding lighting, noise, and traffic disruptions.

Waste – the processing, treatment, and in-situ monitoring of soil onsite eliminates off-site soil waste streams. Irrigation of the soil undergoing treatment with process water will reduce (or eliminate) the volume of water requiring management at the conclusion of the project. Aggregate used to create the pads and roadways will be removed at the conclusion of the project and washed using the soil processing plant (with modifications) to facilitate reuse elsewhere onsite.

Section 5: TNT Project Area Soil Remedy

5.1 Overview

The following sections discuss the technical approach, operational logistics, and schedule for the bioremediation remedy to provide the reader with a high-level overview. Section 5.2 and beyond expand upon this overview discussion and provide a detail account of pre-mobilization, site preparation, and field operation activities.

5.1.1 Technical Approach

The TNT bioremediation remedy is a multi-phase remediation project that relies on physical, chemical, and biological processes to destroy target constituent mass in soil. The remedy will occur in phases, as follows, with each phase having a specific objective.

The first phase includes:

Excavation and Blending – The physical process of excavating source material and blending it on the staging pad for processing reduces the physical and chemical variability of material and begins to break down and increase the surface area of crystalline solids.

Soil Processing Plant – The soil processing plant relies on industry standard mining technologies to reduce the grain size of crystalline material, increasing the surface area available for microbial contact and degradation. The processing plant will physically reduce source mass (i.e., crystalline TNT) particle sizes to less than 2 mm in diameter, and remove larger native aggregate (coarse [12.5 to 50 mm] and fine [2mm to 12.5 mm] oversize) from the material stream. The less than 2 mm in diameter material stream (biofeed) will undergo additional processing and be amended with a commercially available amendment (PeroxyChem's DARAMEND OE®) to stimulate bioremediation. The larger than 2mm material will be washed, verified to meet NRDCSRS, and returned to the excavation.

The next phase of the remedy involves the biological breakdown of target constituents in a controlled and monitored environment.

Ex-situ Bioremediation – The amended biofeed generated by the physical plant processes will be pumped to containment areas (bio cells), where conditions are managed to facilitate and optimize biological degradation over a 4- to 6-month period. Treatment in bio cells will achieve NJDEP's NRDCSRS for target constituents and yield a greater than 95 percent reduction in target constituent mass within a single field season.

The final phase of the remedy addresses in-situ biological degradation to address the remaining target constituent concentrations.

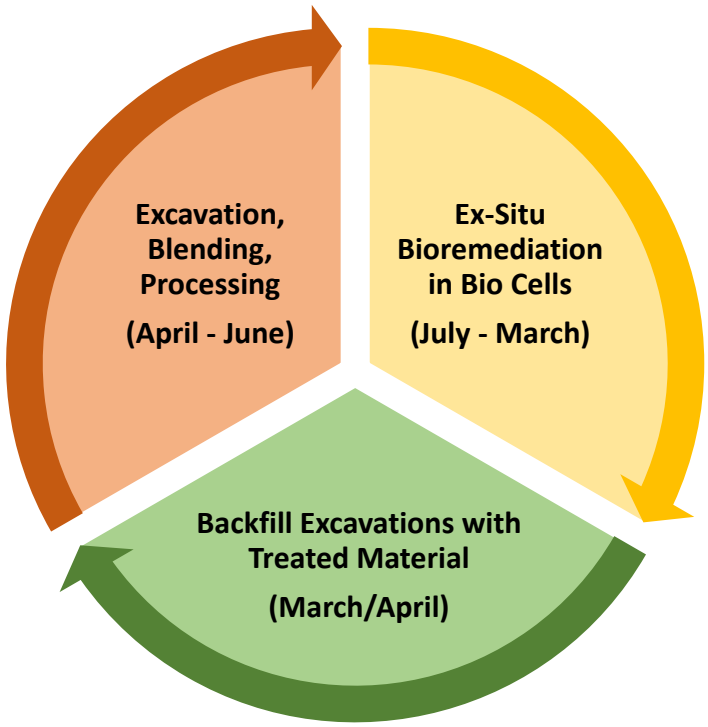
In-situ Biological Degradation – Following the period of management in the bio cells, treated biofeed will be removed and used to backfill the source excavation areas. Target constituent

mass remaining in backfilled material will continue to biologically degrade until constituent mass is exhausted. In-situ processes will be monitored, with achievement of remedial goals expected over a 5-year period.

5.1.2 Field Operations

An estimated 70,000 cubic yards (cy) of material[10] requires treatment, approximately 70 percent of which will end up in the bio cells (remaining 30 percent is oversize). The TNT Project Area layout (**Attachment 6**) contains five bio cells with a total capacity of approximately 15,000 cy. Hercules anticipates construction and processing to fill two bio cells during the first year of operations. This initial effort will focus on optimization of the field process and identifying design modifications (if any) to be incorporated into the construction of the remaining bio cells and subsequent years of field operations.

Treatment involving the first two phases of work (i.e., excavation/blending/processing and ex-situ bioremediation) will occur in a series of annual cycles and require the optimization year and 5 full cycles (years) to complete the ex-situ treatment phase of the project. The annual cycle is illustrated below.



[10] Volume estimate is based on 56,000 cy of bank material, and a 1.25 multiplier to estimate loose (excavated) cy.

Stormwater management, soil erosion and sediment control (SESC) maintenance, and other project area maintenance and monitoring activities will occur throughout the year independent of this cyclical schedule.

Excavation focuses on removing material to target constituents' RDCSRS based on the following:

- Soil concentrations associated with crystalline TNT source mass are greater than TNT's RDCSRS, and use of this conservative target maximizes the likelihood of excavating the crystalline TNT source mass.
- Source mass reduction to target constituents' NRDCSRS is achievable in a single season via ex-situ treatment, as demonstrated by the pilot study. Target constituent concentrations in treated material being used as backfill in excavation areas will be similar to the excavation margins.
- Ongoing reductions from target constituents' NRDCSRS occur following active treatment, as demonstrated in the pilot study, and are expected to deplete remaining source mass and mitigate mass transfer from soil to groundwater.

5.2 Remedy Implementation

This section outlines permitting, pre-mobilization planning, and field activities associated with remedy implementation. In the interest of clarity, the information is presented in chronological order at a consistent level of detail. Where needed, supplemental details are provided in latter sections and referenced accordingly during the sequential implementation sections that follow.

5.2.1 Preconstruction Activities

5.2.1.1 Permitting

Activities proposed in this RAWP will require local, state, and/or federal permitting prior to implementation. These permits may include:

- NJDEP – Division of Water Quality (DWQ) – Discharge to Groundwater Permit
- NJDEP – Division of Land Use Regulation (DLUR) – Freshwater Wetlands/Flood Hazard Area
- Morris County Soil Conservation District (MCSCD) – Soil Erosion and Sediment Control Certification
- Township/County – Site Plan Approval
- Township/County – Traffic Control: Howard Boulevard Entrance
- Township/County – Electrical Permit
- Jersey Central Power & Light (JCP&L) – Electrical Service Drop Authorization

Each of these permits, along with their specific requirements and purposes are addressed further in Section 5.4.

5.2.1.2 Construction Drawings & Specifications

The activities necessary to implement the proposed RA will include the preparation of construction plans and technical specifications in accordance with engineering standards and a level of detail commensurate with the scale and complexity of the project. The construction plans and technical specifications will be developed during final design and represent a component of the contract document package that will support bidding and contractor selection. Bidding will be targeted to qualified firms with demonstrable expertise and experience necessary to maximize the probability of success.

5.2.2 Site Preparation

5.2.2.1 Site Layout & Control

A site layout drawing will be a component of the construction plans to be completed as part of final design. The areas designated on the drawing will be established in the field as part of site preparation activities. These areas will include, but are not limited to, the following:

- TNT Project Area boundary
- Limits of disturbance associated with permits and regulatory approvals
- Excavation area boundaries
- Pads for soil processing plant and other supporting operations
- Staging areas for equipment, materials, and waste
- Locations for loading and unloading materials

Establishment of applicable work zones, as well as security, traffic, and site ingress/egress, are discussed further below.

5.2.2.2 Utility Clearance

A subsurface utility clearance survey will be conducted prior to intrusive site preparation or remedy implementation activities. The clearance will follow processes and procedures outlined in Hercules' Utility Location Policy and documented accordingly.

Multiple utility clearance surveys have been conducted as part of prior investigation work conducted in the TNT Project Area. This information, as well as other Facility-specific knowledge and history, will support the utility clearance survey.

Based on current knowledge, no active utilities exist in the TNT Project Area.

5.2.2.3 Surveying

A pre-construction survey will document pre-disturbance conditions in the TNT Project Area and identify critical infrastructure and/or topographic features of interest that may affect the remedy implementation. Survey work will be performed by a New Jersey-licensed surveyor and documented in an assigned/stamped existing conditions survey plan.

5.2.2.4 Soil Erosion & Sediment Controls

Remedy implementation in the TNT Project Area will disturb more than 5,000 square feet. As such, a Soil Erosion and Sediment Control Plan (SESCP) certification issued by the MCSCD is required. Hercules will apply for and obtain the SESCP certification prior to project implementation. The selected contractor will install controls to mitigate soil erosion and transport of soil or sediment in accordance with the SESCP.

5.2.2.5 Site Access

The primary entrance to the Facility for project staff and contractors will be from Hercules Road. Deliveries and large equipment will use one of the Howard Boulevard entrances to reduce heavy equipment traffic through the residential area of Hercules Road and to most efficiently access the TNT Project Area via existing roads at the Facility. Access routes will include stabilized construction entrances and other controls (e.g., decontamination pad) in accordance with the New Jersey Soil Erosion and Sediment Control (SESC) Standards.

The existing Facility perimeter fence will be relied upon for security. A secondary chain link fence may be installed around portions of the TNT Project Area to exclude wildlife, trespassers, and/or control access by project staff. Fencing may also be used to demarcate TNT Project Area boundaries and avoid disturbance to adjacent areas.

5.2.2.6 Decontamination Pad

Decontamination of equipment will be performed at a temporary decontamination pad constructed near ingress/egress roadways into the TNT Project Area. Excavation equipment and vehicles leaving the TNT Project Area that directly contact impacted material will be decontaminated on this pad. The decontamination area will consist of a stone covered pad, which will be bermed and lined to facilitate the flow of wash water to a sump that will be constructed at the lowest point. Water generated during decontamination procedures will be pumped to the water storage basin for recirculation through the processing plant. The decontamination pad location will be established as part of final design, will take into consideration traffic routes, and may be periodically relocated to accommodate the construction activity.

5.2.2.7 Clearing & Grubbing

Much of the TNT Project Area is vegetated, primarily as grasses and forbs interspersed with stands of shrubs and trees. Clearing and grubbing of vegetation will be necessary within the Project Area to facilitate ground surface grading and establishment of project-related infrastructure (e.g., traffic routes, pads, bio cells, water management basins), as well as access

to the soil surface in excavation areas. Cleared vegetation will be chipped and used as ground cover as necessary within the TNT Project Area.

5.2.2.8 Utilities

5.2.2.8.1 Electric

The soil processing plant will require a reliable power source to operate pumps, conveyor systems, screeners, and other supporting equipment. Worker support areas (e.g., parking lots, trailers) will also require a power source. Currently, there is not access to power in the TNT Project Area. Temporary power during site preparation may be provided by a diesel generator, but a semi-permanent source of power will be brought to the TNT Project Area via a power drop from the local power company (JCP&L) to support operations. A power drop provides a reliable source of power, has a lower potential to influence the surrounding community via noise and odor, has a smaller environmental footprint, and is likely more efficient and cost-effective than a generator.

The drop location and power demands will be identified during final design.

5.2.2.8.2 Water

As stated above in Section 4.2.4, water will be required for the process plant operation. To the extent practicable, captured and contained stormwater will be used as the primary source of make-up water. It is likely that contained stormwater volumes will be insufficient to meet the demands of startup during the first processing season. A number of options exist to meet this initial demand. Hercules maintains an operating water supply well network onsite capable of producing 1,700 gallons per minute. This onsite potable water source can supply the processing plant via an overland piping system (e.g., welded HDPE). Alternatively, water can be obtained from nearby Morris County Municipal Utilities Authority water supply lines and/or potable water deliveries via truck.

To reduce potential for freeze damage to the overland lines, all lines will be drained and pigged to ensure joints and line integrity are maintained throughout the winter non-working season. During initial spring start-up, pressure testing of lines will be completed with potable water and any leaking joints or lines will be replaced prior to beginning operations that season.

5.2.2.9 Civil Site Preparation and Grading

Existing Facility roadways require improvement to support remedy implementation, and new roads will need to be constructed to provide access and facilitate traffic flow within the TNT Project Area. Following clearing and grubbing, ground surface improvements will be required to support infrastructure associated with remedy implementation. Construction of access roads, processing plant equipment pads, soil blending/staging pads, reagent storage pad, bio cell pads, and water management tank pads will require grading to level uneven areas and develop positive drainage. In-situ soils may undergo physical compaction (if necessary) to enhance strength characteristics. Crushed stone pads and access roads will be constructed atop geotextile fabric placed on the graded ground surface.

The actual locations, specifications, and dimensions of the temporary access roads and crushed stone equipment pads, water management units and drainage features will be selected based upon equipment specifications and access/water management requirements developed during final design. Final design will occur under the direction of a New Jersey-licensed Professional Engineer (NJ PE), and the final construction drawings will contain a NJ PE signature and seal.

5.2.2.10 Bio Cell Construction

Bio cells will be constructed atop graded, crushed stone pads using conventional concrete bin blocks stacked three high (6 feet). Each bio cell will be lined with a dual-layer liner system that provides secondary containment/leak detection capabilities. A series of sumps will be installed to facilitate dewatering and moisture management.

The bin block wall is modeled as a standard gravity retaining wall, and internal stability related to the interaction between the stacked units of bin blocks is generally not considered. As indicated in Section 4.2.4, the bin block bio cell evaluation indicated stable conditions can be attained. The area between bio cells will likely be filled to create a stable working surface and buttress the bio cell wall against the lateral force of the biofeed within.

Once filled, precipitation at the bio cells will be managed as non-contact stormwater via a cover system that drains to the permeable working surface between bio cells.

Liner material selection, wall stability and buttressing, moisture management equipment, and a cover system will be addressed during final design. Final design will occur under the direction of a NJ PE and the final construction drawings will contain a NJ PE signature and seal.

5.2.2.11 Water Management Basin

Process water storage will be designed as an above ground modular basin(s) with dual layer liner for leak detection. Design drawings will include grading and ground surface preparations necessary to support construction of the basin(s). Based on capacity estimates (approximately 2.5 million gallons) from a preliminary water budget (Section 4.2.5.1), multiple basins may be constructed to more effectively manage sedimentation and solids settlement and maintain capacity to accommodate storm events.

Water management basin specifications and construction requirements will be developed during final design. Final design will occur under the direction of a NJ PE and the final construction drawings will contain a NJ PE signature and seal.

5.2.3 Soil Processing Plant

Following final process plant design and engineering, plant procurement and construction will begin. The plant consists of a combination of industrial mining equipment, custom fabricated structural elements, and common material management and plumbing supplies (e.g., valves, piping, pumps, gauges). **Attachment 6** illustrates the conceptual plant layout. Plant design will occur under the direction of a NJ PE and the final construction drawings will contain a NJ PE signature and seal.

The plant is being designed specifically for this project and will be constructed as a modular unit, with assembly, fit-out, and testing occurring offsite. Upon completion, the plant will be labeled, disassembled, and loaded onto a series of trucks for transport to the Facility.

At the Facility, the plant will be offloaded and assembled on the constructed pad under the direction of ART Engineering, LLC (plant designer and builder). Once assembled, the plumbing and electrical connections will be made and the plant will be wet tested prior to processing soil. Testing will assess the function of both plumbing and electrical systems.

The current schedule has site preparation and plant assembly occurring through summer and fall, and the initial soil processing effort beginning the following spring. As such, wet testing in the fall will require winterization of the plumbing before the winter.

5.2.4 Field Operations

Field operations will commence following permitting, site preparation, and process plant construction/delivery/assembly onsite. Field operations will occur on an annual schedule or cycle to achieve the following milestones:

March

- Begin field operations
- Remove bio cell covers (Years 2 and beyond)
- Empty bio cells, backfill previously excavated areas

April through June

- Excavate soil requiring treatment
- Blend excavated soil to create plant feed
- Process plant feed in soil processing plant
- Fill bio cells with biofeed
- Manage soil moisture in filled bio cells (incl. install covers)

July through November

- Process confirmation monitoring (to begin following filling of first bio cell each year)
- Manage soil moisture in bio cells

November through March

- Meet with NJDEP/LSRP to provide status update and review monitoring data
- No monitoring activities (soil microbes inactive when soil temperature is less than 50 degrees Fahrenheit [°F])

The following sections describe field operations in the general sequence outlined above.

5.2.4.1 Soil Preparation

Soil preparation consists of two primary steps: excavation, blending, and staging, and processing through a soil processing plant with the single objective of concentrating target constituent source mass in a biologically-accessible form (high surface area to volume ratio) in a physically- and chemically-homogenous biofeed material.

5.2.4.1.1 Excavation, Blending, and Staging

Excavation focuses on removing material to target constituents' RDCSRS based on the following:

- Soil concentrations associated with crystalline TNT source mass are greater than TNT's RDCSRS, and use of this conservative target maximizes the likelihood of excavating the crystalline TNT source mass.

- Source mass reduction to target constituents' NRDCSRS is achievable in a single season via ex-situ treatment, as demonstrated by the pilot study. Target constituent concentrations in treated material being used as backfill in excavation areas will be similar to soil at the excavation margins.

- Ongoing reductions from target constituents' NRDCSRS occur following active treatment, as demonstrated in the pilot study, and are expected to deplete remaining source mass and mitigate mass transfer from soil to groundwater.

Generating a feedstock for the soil processing plant requires a precise technical excavation, such that excavated and blended soil stockpiles have relatively consistent physical and chemical characteristics. Based on pilot and verification study results, an average feedstock concentration of approximately 2,000 milligrams per kilogram (mg/kg) TNT will be achieved by blending high concentration source area soil containing crystalline TNT with soil from adjacent areas with lower target constituent concentrations. An Excavation, Blending, and Staging (EBS) Plan, to be prepared as part of final design, will outline an excavation sequencing strategy to maintain a generally consistent feed concentration at the processing plant each processing year.

Soil excavation and blending will create a well-mixed feedstock with consistency in both physical (e.g., grain size distribution) and chemical (i.e., target constituent concentrations) characteristics. Consistency in feedstock at the front end of the soil processing plant will result in a predictable production rate of biofeed and oversize fractions. The EBS Plan will address excavation sequencing, blending procedures, and stockpile staging progressions to maintain a steady feedstock for plant operation. Elements to be expanded on and refined in the EBS Plan follow.

Secondary COCs (e.g., metals) were assessed during initial excavation planning, and are addressed in **Appendix C**. Where necessary, soil containing secondary COC concentrations requiring additional remediation that occur in excavation areas will be managed such that the treated soil can be returned to the source excavation area where remediation of secondary COCs

can occur. As indicated in **Appendix J**, certain soil containing lead will be managed via excavation and offsite disposal independently from the remedy outlined herein.

Excavation Process

- Concrete rubble stockpiles in excavation areas will be relocated to an appropriate area nearby in the TNT Project Area
- Soil will be removed via tracked excavator based on refined delineation characterization data; no post excavation sampling will occur
- Excavated soil will be stockpiled on the soil staging pad (an impervious surface with containment) with discrete stockpiles based on concentration and volume per the EBS Plan
- Stockpiled soil will be processed to remove large debris (greater than 50-mm diameter) via a trommel on the soil staging pad. Large debris stockpiles will be visually screened for TNT particles and residual adhered soil, once confirmed visibly free of TNT and adhered soil, the aggregate will be returned to the source excavation area.

Blending Process

- Multiple staged stockpiles will be blended together via excavator to create feed stockpile
- Blending procedures to be specified in EBS Plan
- Feed stockpile will be brought from the staging pad to the plant via front-end loader

Staging Process

- Blended stockpiles that equate to 3 days of processing will be staged and ready throughout the process
- Each stockpile will be sized to approximately 1 day of plant feed (~260 cy)
- Staged stockpiles for subsequent days will be maintained under plastic sheeting or in a moistened condition to avoid wind-blown dust

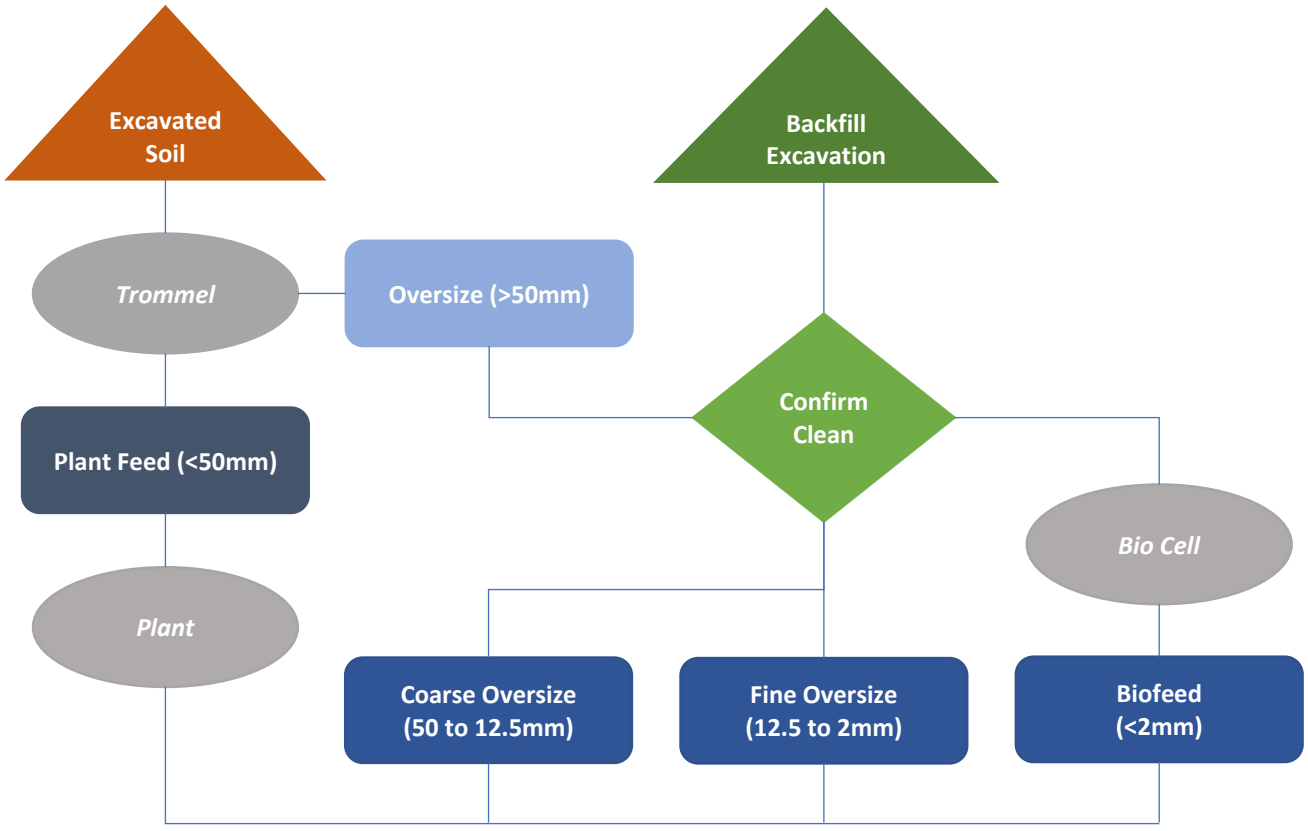
Each step of the excavation, blending, and staging process illustrated in the following graphic increases the homogeneity of the mixture and breaks down soil aggregates and crystalline TNT particles in the soil mixture.

5.2.4.2 Physical Soil Processing

The excavation and blending process begins the physical processing of the soil and breakdown of the TNT particles. Further grain size reduction and aggregate separation occurs in the soil processing plant.

The soil processing plant will physically segregate oversize material, reduce TNT particle grain size, and concentrate target constituent source mass in the biofeed fraction. The process relies on industry-standard mining and aggregate management processes and equipment. Based on source soil grain size distribution information, approximately 70 percent of the feedstock will emerge from the plant as biofeed, with the remaining 30 percent distributed between two oversize fractions (coarse oversize [greater than 12.5 mm in diameter] and fine oversize [between 12.5 and 2 mm in diameter]). The plant imparts sufficient physical energy into the feed material via a number of processes (e.g., attrition scrubber, drum scrubber, blade mill) to breakdown crystalline TNT nodules to less than 2 mm and entrain them in the biofeed; yielding oversize fractions visibly free of TNT (e.g., washed stone). Oversize fractions will be tested in accordance with the *TNT Bioremediation Process Confirmation Sampling Plan* (**Appendix D**) and *Quality Assurance Project Plan* (**Appendix E**) and evaluated for reuse as excavation backfill material under the *TNT Project Area Soil Reuse Plan* (**Appendix F**). The remaining fines fraction (biofeed) will be amended with DARAMEND OE® and conveyed to bio cells for ex-situ bioremediation.

The following illustration tracks the segregation and disposition of soil fractions during the process.



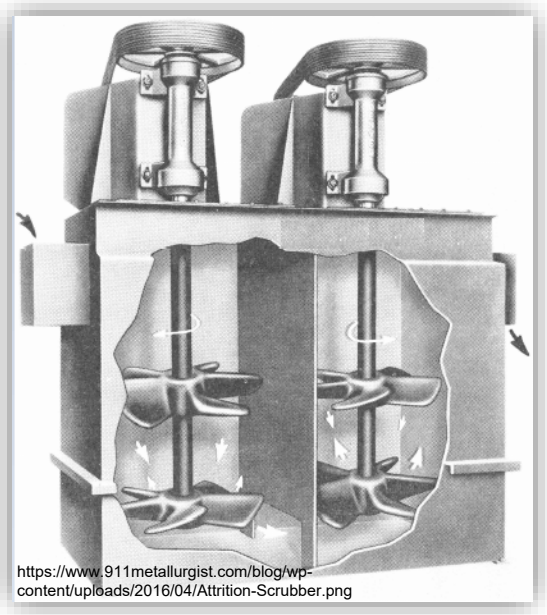
Attachment 6 provides process plant schematics and a process flow diagram of the conceptual treatment train. Specific elements of the plant include:

Wet screens – high pressure water wash as material passes over a vibratory screen deck. Undersized material passes through the deck while oversize material remains on top. Each material stream moves on to another treatment step per the process flow diagram.

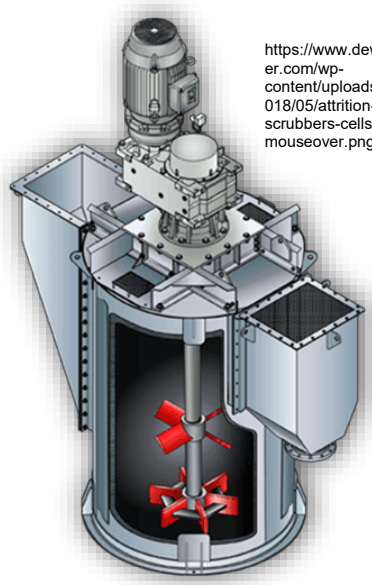
Aggregate conditioner (blade mill) – a rotating mechanical device that creates impact between aggregate particles and fixed or rotating components of the unit. Soft material adhered to harder aggregate is broken down, and the harder native material impacting the TNT particles will reduce TNT particle sizes. This mechanical wet process improves screening efficiency, reduces TNT particle sizes, and yields cleaner oversize fractions.

https://s3.amazonaws.com/mclanahan.com/images/Products/Wet/Aggregate-Conditioners/_resizeMedium/Aggregate-Conditioner-5.JPG?mtime=20180612101102

Attrition scrubbers – tanks containing a soil slurry and agitators that use the natural abrasive properties of the slurry to abrade entrained particles; the softer TNT material will be broken down as it contacts the harder native materials.



https://www.911metallurgist.com/blog/wp-content/uploads/2016/04/Attrition-Scrubber.png



https://www.dewater.com/wp-content/uploads/2018/05/attrition-scrubbers-cells-mouseover.png

Sand screw – an auger that separates sand from fines in a settling tank; the sand is coarse enough to be carried up the auger and discharges out one end, while fine material remains in the low end of the device.

https://i2.wp.com/www.diamondequip.com/wp-content/uploads/2016/06/TRIO_fmw4.jpg?resize=700%2C400&ssl=1

These primary treatment devices are connected via a series of conveyors, pumps, and pipes. Prior to leaving the plant, the biofeed is amended with DARAMEND OE®. The slurried, blended material is then pumped to the bio cells. A closed-cycle water loop will supply water to the plant. Process water is collected and recirculated to support continuous processing, with makeup water added as needed via the water source(s) described in Section 5.2.3.8. Ultimately, the process plant generates two oversize fractions free of TNT particles and concentrates target constituent source mass in the biofeed fraction. Oversize fractions will be managed and confirmed clean per the PCSP (**Appendix D**) prior to being returned to the excavation area.

The processing plant will be operated by a trained crew with discrete operational responsibilities. The plant design will include a basic programmed logic control system and motor interlocks to orchestrate the startup and shutdown of the plant and facilitate unplanned shutdowns without damaging equipment. ART Engineering, LLC, the designer and builder of the plant, will develop an Operations and Maintenance Manual (O&M Manual) and Plant Operator training program. Initial seasonal startup will occur under the guidance of ART Engineering, LLC, and they will remain available for troubleshooting once the plant is turned over to the operators.

5.2.4.2.1 Seasonal Shutdown & Startup Processes

The operation of the plant will occur in cycles, or seasons, with processing to fill bio cells occurring approximately from April 1 to June 30. Once the bio cells are filled, the process plant will undergo gross decontamination and winterization. Portable equipment will be stored in a secure, locked building onsite to prevent theft or vandalism. Winterization will include the de-energizing of the process plant equipment and the draining/purging of all process and water lines.

A cover system may be installed over the processing plant during the non-operational period between July and March such that precipitation can run to ground rather than be contained on the process pad (contaminated) and collected in the water management basin. The necessity for and specifications of a cover system will be addressed as part of final design.

The winterized and/or covered process plant will be inspected routinely during the non-operational period.

5.2.4.3 Ex-Situ Bioremediation

Biofeed arrives at the bio cells in a slurried state, pumped from the soil processing plant after being amended with DARAMEND OE®. The presence of DARAMEND OE® drives strongly reducing soil conditions and provides a carbon and nutrient source to stimulate the native microbial community in the soil and facilitate biological reduction of target constituents. The effectiveness of DARAMEND OE® has been demonstrated on E&E compounds across a number of DoD and private industry projects (**Appendix H**) and proven during the pilot study conducted at the Facility (**Attachment 3**). Greater than 95 percent reduction in target constituent mass is expected to occur during the ex-situ bioremediation phase of the remedy.

Ex-situ bioremediation is a generally passive phase of the project that occurs in the bio cells. While passive with respect to material processing and movement, the maintenance of optimal biologic conditions in the bio cells is critical to facilitating target constituent degradation.

5.2.4.3.1 Bio Cell Management

5.2.4.3.1.1 Filling

Amended biofeed leaves the plant in a slurried state and is pumped to the bio cells being filled. A series of valves allows plant operators to direct flow from the plant to the desired bio cells.

Upon arrival at the bio cells, the slurried biofeed receives a metered dose of flocculant polymer to facilitate solids settling and dewatering in the bio cell. At the bio cell, a biofeed discharge line attached to the boom of an excavator is used to sequentially fill the bio cell with biofeed beginning at one end and progressing to the other. As the biofeed is discharged to the bio cell, the polymer facilitates coagulation of solids, producing a flow of freely draining water in the bio cell. This water is contained in the bio cell and pumped out via a series of sumps around the perimeter of the bio cell. The water is recirculated to the water storage basin via a solids settling tank where it is drawn back into process plant operations.

The flocculent polymer is a cationic water-soluble acrylamide polymer used throughout the wastewater treatment industry in sludge and solids dewatering processes. The pilot study demonstrated that the polymer does not influence the performance characteristics of DARAMEND OE® or change the soil conditions (pH, moisture retention). The polymer's role is limited to the initial dewatering activities, after which it degrades in soil. Degradation occurs quickly via microbial, chemical, and mechanical means. Per the manufacturer, polymer concentrations in soil decrease by 70 percent over 28 days. As such, the polymer will be substantively degraded by the time the treated soil is ready to return to the excavation areas (approximately 300 days).

5.2.4.3.1.2 Cover

Once a bio cell is full, an arched span or low-profile cover will be installed over the cell to shed precipitation and avoid stormwater contact with biofeed/treated material containing target constituents. Hercules anticipates using commercially-available covers that are engineered and tested to withstand the environmental conditions at the Facility (e.g., wind, snow load, ultraviolet radiation).

5.2.4.3.1.3 Soil Moisture

Prior to discharge into the bio cells, the biofeed is dosed with a flocculating agent to facilitate rapid dewatering upon discharge. The biofeed will passively dewater and be maintained at a moisture content approximately 80 percent of the water-holding capacity of the material. This moisture content maximizes wetted interstitial pore space in the soil matrix where biological degradation occurs.

Soil moisture will be maintained using a mist/sprinkler system installed within the covered bio cell. Irrigation water will be pumped from the accumulated stormwater and recycled process water contained in the water storage basins.

Irrigation rates will be based on estimated evaporation rates and the soil's water holding capacity. These details will be addressed during final design and may be adjusted in the field to maintain optimal soil moisture.

5.2.4.3.1.4 Monitoring

Monitoring will occur in accordance with the *TNT Bioremediation Process Confirmation Sampling Plan* (**Appendix D**) and *Quality Assurance Project Plan* (**Appendix E**). Monitoring results will confirm target constituent concentrations less than NJDEP NRDCSRS to facilitate reuse in accordance with the *TNT Project Area Soil Reuse Plan* (**Appendix F**) as fill in excavated areas where ongoing in-situ biodegradation will occur.

Once filled, baseline monitoring data will be collected in accordance with the PCSP (**Appendix D**), and a cover will be installed over the bio cell to maintain a consistent soil moisture content and avoid capturing and containing precipitation runoff in the bio cell.

Monitoring of moisture content, pH, redox potential, and soil temperature (critical variables that facilitate bioremediation) will occur in accordance with the PCSP (**Appendix D**). Monitoring may occur manually in the field using probes/instruments or via in-situ probes with data logging and/or remote data transmission capabilities.

The pilot study demonstrated a rapid reduction in target constituent concentrations over the 12-week study period. Per the PCSP, bio cell monitoring of target constituent concentrations will occur upon filling (Day 0) and at 4-week intervals thereafter (Days 28, 56, 84). Soil temperature will continue to be monitored after Day 84, and if soil temperature is at or above 50°F at subsequent 4-week intervals (e.g., Day 112, 140), additional rounds of monitoring data will be collected.

In accordance with the PCSP, process confirmation monitoring will continue until data demonstrate attainment of ex-situ bioremediation success criteria for target constituents (i.e., NRDCSRS). Once success criteria are achieved, process confirmation monitoring will cease and the treated biofeed will be used as backfill (see Section 5.2.5.4.3). The final round of process confirmation sampling will assess treated biofeed for the full list of constituent classes present in excavation source material per the secondary COC evaluation provided in **Appendix C**.

5.2.4.3.1.5 Emptying

After process confirmation monitoring generates data indicating that the treated biofeed is suitable for use as backfill in excavation areas, the covers will be removed, and equipment mobilized to the empty the bio cells. Emptying will occur via long-reach excavators working from either side of the bio cell. Excavators will load treated material into articulating dump trucks for transportation to the excavations requiring backfill. Excavators will be equipped with wide grading buckets fitted with a rubber scraping edge to protect the integrity of the bio cell liner.

Process confirmation testing will occur in late summer and fall, such that analytical results are received and reviewed prior to the end of the calendar year. Results will be tabulated and presented to the NJDEP and LSRP in a progress status update meeting each winter prior to field teams remobilizing to the field to empty the bio cells. Concurrent with emptying the first bio cell in the spring, material will be excavated from source areas and blended on the processing pad. Once the first bio cell is empty, the processing plant will begin processing material and refilling the empty bio cell.

Equipment and labor will be available to empty the bio cells at a faster pace than the processing and filling, ensuring that there is always an empty bio cell and that the processing plant can operate without interruption.

5.2.4.3.2 Water Management

Water is critical to both the process plant operation and the establishing and maintenance of optimal soil conditions to support biological degradation in the bio cells.

5.2.4.3.2.1 Process Water

Process water demands are driven by the volume of water required to wash material on the wet screens and that are required to maintain the appropriate slurry density for attrition scrubbing and biofeed pumping to the bio cells. As biofeed is discharged to the bio cells, return water from dewatering will be pumped back to the water management basin to supply plant operations.

Initial startup water during the first year of operation may be provided by containing precipitation that falls in the bio cells (uncovered before first use) and water management basin. Additional water required to meet initial demand will be available from the water supply sources discussed in Section 5.2.2.8.2.

Process water from the water management basin will be used to irrigate the biofeed undergoing bioremediation in the bio cells. Bioremediation is most effective when soil is maintained between 80 and 90 percent of its water holding capacity. Irrigation will occur by placing a hose beneath the cover of the bio cell and pumping for a fixed duration of time (or known volume). Pumping duration and/or volume will be dictated by field measurements as outlined in the PCSP (**Appendix D**).

5.2.4.3.2.2 Stormwater

Precipitation represents an important component of the project. In general, the intent is to manage project infrastructure in a manner that minimizes the volume of precipitation that contacts contaminated material (or surfaces) and requires collection. To achieve this goal, cover systems will be used at much of the passive infrastructure (e.g., water management basin, filled bio cells). Where possible, other infrastructure will be covered once processing is completed for the season so that precipitation between July and April can be managed as non-contact stormwater and discharged to the ground surface. Stormwater runoff will be managed and discharged in accordance with applicable local, state, and federal regulations. Given the water demands of the project, at times precipitation may be deliberately contained as a source of makeup water.

The following elements related to precipitation will be considered during final design:

- Maintaining cover over bio cells unless actively being filled or emptied, resulting in no more than two bio cells open at any one time.
- Maintaining cover over the water management basin at all times
- Stockpiling covers in the blending and staging pad area that direct stormwater off the pad (a contaminated surface)

Section 4.2.5.1 summarizes a preliminary water budget that considers the elements above. This initial effort will be refined and assist in the development of best management practices (BMPs) pertaining to precipitation and stormwater that will be developed during final design. Project-specific BMPs will be documented in a stormwater management plan. The stormwater management plan will support obtaining the necessary permits and approvals related to stormwater management.

Final design will also explore the ability to beneficially reuse process water into the backfilled excavations to increase soil moisture and expedite the in-situ degradation of residual target constituents. Conceptual design activities to date indicate that:

- Recirculated process water in the water storage basins will be at/near saturation for target constituents and microbial communities at the conclusion of each processing season.

- Recirculation of the water within the water storage basin after the conclusion of the processing season will maintain colloidal material in the water column. This colloidal material will include soluble fractions of DARAMEND OE® and will facilitate degradation of aqueous phase target constituent mass within the basins. Degradation will occur rapidly under these conditions.

- Following a period of recirculation to facilitate degradation of target constituent dissolved phase mass, the microbial-rich process water could be surface applied and allowed to percolate into the treated material used to backfill the excavations.

- This approach could be permitted under a NJDEP Discharge to Groundwater Permit that will authorize adding DARAMEND OE® to the bottom of the excavation prior to backfilling.

5.2.4.4 In-Situ Biodegradation

In-situ biodegradation will occur in excavation areas backfilled with treated materials. DARAMEND OE® maintains its effectiveness in soil for approximately 5 to 7 years.

In-situ degradation will be monitored in accordance with a long-term monitoring plan (LTMP). The LTMP will be developed following review of the information generated by the PCSP (**Appendix D**) activities through the first process monitoring season and approved by the Facility's Licensed Site Remediation Professional (LSRP) prior to implementation.

5.2.4.4.1 Excavation Backfilling

Backfilling of excavation areas with treated biofeed from the bio cells will occur in accordance with the *TNT Project Area Soil Reuse Plan* (**Appendix F**). DARAMEND OE® will be blended into the native material at the base of the excavation prior to backfilling. Backfilled material will not be compacted to retain high moisture content in interstitial pore spaces and facilitate in-situ degradation. Interstitial pore space will be increased via the blending of clean oversize fractions at proportions similar to native material. Blending will occur via bucket mixing as the excavation is backfilled. This secondary polishing phase will continue until residual mass is depleted and no longer provides the food source needed to maintain a robust microbial community.

In anticipation of settling over time, the backfilled excavations will be mounded, with a shallow trough at the edge of excavation to assist in percolation of surface-water runoff. In-situ strength of the backfilled material will be somewhat low and will not be capable of supporting large construction equipment. Therefore, safety fencing and enhanced erosion control measures will be placed around the individual areas that have been backfilled until such time that soils have achieved remedial goals and natural consolidation has improved support capabilities.

Following ex-situ bioremediation and backfilling, sampling at backfilled excavations will monitor long-term biodegradation of residual target constituent mass in treated biofeed. Sampling strategy and procedures will be outlined in a long-term monitoring plan (LTMP). The LTMP will include monitoring and adaptive management strategies based on an assessment of biofeed homogeneity using data collected as part of process confirmation monitoring, as outlined in the PCSP (**Appendix D**).

5.2.4.4.2 Site Restoration

Disturbed areas not subject to long-term monitoring (e.g., areas adjacent to excavated areas) will be seeded with annual rye (*Festuca perennis*) to establish stabilizing cover and a native seed mixture to provide long-term vegetative cover of a diverse native plant community. Additional details regarding restoration of vegetative cover to portions of the TNT Project Area will be included in the SESCP and Restoration Plan approved as part of NJDEP – DLUR permits.

Project infrastructure will be managed as follows at the conclusion of the project.

Aggregate (temporary roadways and pads) will be removed from the ground surface and run through the soil processing plant, oversize fractions will be stockpiled for reuse following confirmatory testing in accordance with the PCSP. Fines will be handled as biofeed and sent to a bio cell for treatment. Once confirmed clean per the PCSP, the fines will be returned to the TNT Project Area in accordance with NJDEP's Fill Guidance.

Water management basins and bio cells will be deconstructed once emptied for the final time. Liner material, sumps, and other infrastructure in contact with biofeed will be either decontaminated or disposed of, concrete bin blocks will be staged for reuse or sold.

The soil processing plant will be decontaminated and broken down for transport and storage at the end of the final soil processing cycle and once treated material in the bio cells has been confirmed clean. As equipment is removed from the plant process pad, the underlying aggregate will be managed as noted above.

Upon completing the site restoration activities, equipment, excess materials, and other miscellaneous items will be demobilized from the Facility. Equipment used during the remedial action will be decontaminated, as necessary, prior to removal from the TNT Project Area.

Area of exposed ground surface will be seeded in accordance with the SESC Plan to establish vegetative cover. Areas regulated by NJDEP – DLUR will be addressed in a Restoration Plan submitted as part of the NJDEP – DLUR permit application.

5.2.5 Health & Safety

Activities outlined in this RAWP will be performed in accordance with the site-specific Health and Safety Plan (HASP) (or equivalent project-specific document) for the Facility. The HASP will comply with requirements set forth in accordance with Occupational Safety and Health Administration (OSHA) standards for hazardous waste operations (29 CFR 1910.120).

Additional health and safety controls will include the identification of designated zones onsite for specific activities including parking, eating, visitors, etc. Exclusion zones will be designated as needed to manage potential health and safety hazards regarding plant operation. Zones may be identified or altered as necessary by the Site Safety Officer (SSO). Prior to the start of each work day, the SSO will hold a meeting with all onsite personnel to discuss potential health and safety hazards for the tasks scheduled for that day.

Hercules will also coordinate with local police and fire departments prior to implementation to make them aware of implementation activities and related influences on risk and safety (i.e., increased Facility traffic, truck deliveries, heavy equipment operations).

5.2.5.1 Dust/Air/Noise/Odor

Environmental monitoring will be conducted throughout active implementation periods (e.g., April through June) to ensure the safety of field personnel as well as avoid or minimize impact on the surrounding community. Monitoring will include a combination of pre-implementation baseline perimeter and ambient monitoring for parameters including dust and project-related constituents in air, noise, and odors. Appropriate threshold values for monitored parameters and associated control measures, best management practices, and response actions will be outlined in the project-specific HASP.

The biodegradation process involves fermenting the carbon source(s) present in the bio feed, resulting in the production of carbon dioxide (CO_2), hydrogen, butyric acid and other gases commonly associated with fermentation processes. Odors associated with these gases will be monitored during the initial year of operation to assess the potential for nuisance impacts to the community. Design modifications for the bio cell cover systems can be made, if needed, to mitigate potential nuisance odors. The gases produced during biodegradation are not regulated as Hazardous Air Pollutants (HAPs) by the USEPA, and thus do not require Maximum Achievable Control Technology (MACT) compliance.

5.2.5.2 Gas

The biodegradation process generates CO_2 gas. Given the presence of lined walls extending above the surface of the treated material and a cover over the bio cells, the collection and concentration of CO_2 is possible, and could create conditions with insufficient oxygen in the breathing zone for workers monitoring the cells.

The potential for these conditions will be addressed in the HASP, and active breathing zone monitoring will occur when work is occurring in proximity to a covered bio cell. Covers will be pulled back prior to sampling and sufficient time waited before entering the area to sample such that the sampler's breathing zone contains ambient air (confirmed via instrument readings).

5.2.6 Contingency Plan

The remedial design presented in Sections 4 and 5 is grounded in prior science conducted by DoD and private industry, and proven effective under Facility-specific conditions during the TNT pilot study and post-study monitoring. While variables and outcomes have been studied and will continue to be managed through final design, contingency planning for unanticipated outcomes is warranted.

The following list provides potential outcomes related to operations and monitoring, each followed by a related response action.

Operations

- Excavation volume increases/decreases → increased/decreased number of cycles required to complete the remedy
- Process plant productivity increases → bio cells filled sooner, allowing for longer active degradation period before soil temperatures drop below 50°F.
- Process plant productivity decrease → process soil through the third week of July, allowing for approximately 90 days before soil temperatures drop below 50°F. Bio cell(s) may remain empty or partially filled based on productivity.
- TNT detonation during grain size reduction process → manage risk to personnel via restricted access to areas of potential detonation (e.g., blade mill) and equipment covers to contain ejected debris and process water.
- Process plant and/or equipment fire → suspend operations until equipment can be repaired and returned to service.
- Excess treated biofeed during excavation backfilling → stockpile on process pad until new/next excavation area is opened.
- Process equipment failure → suspend processing and make necessary repairs; process plant will be equipped with an emergency shutdown procedure initiated via a series of motor and pump interlocks to ensure safe and prompt plant shutdown. Backup equipment (e.g., pumps, valves) will be maintained onsite to expedite return to operation. Large fixed equipment (e.g., wet screens, conveyors) will be procured from reputable vendors that can provide emergency service and repairs if required. Heavy equipment (e.g., excavators, loaders) will be inspected daily and taken out of service for repairs as needed.
- Infrastructure (i.e., water management basin, bio cell) failure → features will be equipped with secondary containment, processing will be suspended, and the necessary repairs made;

redundancy (i.e., multiple basins and bio cells) will provide operational flexibility in the event of a failure.

- Major storm events → perform scheduled shutdown of operations and prepare work area for forecasted event; manage process water storage in bio cells as needed to provide excess capacity in water storage basins (design specifications accommodate 100-year storm event[s]).
- Vandalism → cease operations until the vandalized and/or damaged equipment is restored to operational status; improve TNT Project Area security to reduce the likelihood of recurring incidents.
- Force majeure/civil unrest/acts of God → cease operations and prepare TNT Project Area for pending events; if prior knowledge is not possible, manage the situation as an emergency in accordance with the project-specific HASP, ensure the safety of personnel, and shut down operations.
- Traffic/Closure of Public Roadways → identify alternate routes/access points, stockpile supplies onsite ahead of anticipated closures (e.g., construction); project sequencing does not require daily traffic of large trucks over public roadways, following initial mobilization at the beginning of the project (or season) routine deliveries will occur on a weekly or biweekly basis and be limited to one or two trucks. Traffic routes for vehicles other than employee/worker vehicles will avoid using the Hercules Road entrance to the extent practicable.
- Supply chain disruption (heavy equipment mobilization) → activities will be delayed until the specified equipment or a suitable alternative can be mobilized to the Facility.
- Supply chain disruption (DARAMEND OE®) → weekly deliveries are anticipated to meet plant demands, absent DARAMEND OE® processing will be suspended until an adequate and reliable supply is obtained.

Monitoring

- Oversize fractions sampling results greater than NRDCSRS → recirculate stockpiled fraction(s) through the plant and retest, associated plant modifications (wash screen retention time increase) will be addressed in the O&M Manual for the plant.
- Analytical data variability within or between bio cells → analyze discrete samples and evaluate data for sources of variability; evaluate process plant operations influencing biofeed homogeneity.
- Target constituent concentrations in biofeed/bio cells greater than NRDCSRS at end of cycle → leave biofeed in bio cell for another season, continue sampling program; will reduce productivity and may increase number of seasons required to complete the remedy; evaluate operational changes (e.g., increase amount of DARAMEND OE added).

- Target constituent concentrations in in-situ treated/backfilled biofeed not demonstrating reducing trend → assess soil conditions (e.g., moisture, oxidation-reduction potential) more frequently, address deficiencies (e.g., irrigate, in-situ mixing with DARAMEND OE®).

Hercules will notify the appropriate entities (e.g., LSRP, NJDEP, MCSCD, Roxbury Township) of unanticipated outcomes based on regulatory requirements and project approvals. The PCSP (**Appendix D**) addresses process adaptation(s) in response to monitoring results. The process plant O&M Manual will contain response procedures for atypical operating scenarios (e.g., emergency shutdown). These procedures will be addressed and trained on as part of the process plant operator training program and drilled during plant startup.

Overall, the process is robust and remains adaptable to accommodate unanticipated outcomes without compromising the ability to successfully implement the overall remedy and achieve remedial action objectives.

5.3 Permits & Approvals

Certain activities proposed in this RAWP will require local, state, and federal permits. Engineering design and construction documents will be prepared for the proposed activities, and certified, as required, by a NJ PE. These documents will be included with permit application submittals that will be required prior to and as part of implementing the scope of work proposed in this RAWP.

Potentially required permits identified as part of the remedial activities are described in detail below. The comprehensive evaluation of potentially regulated activities also identified regulations under which proposed activities do not require permits (i.e., air compliance).

5.3.1 NJDEP – DWQ – Discharge to Groundwater Permit

A Discharge to Groundwater (DGW) permit will be obtained in accordance with N.J.A.C. 7:14A-7. Discharge to groundwater activities will include:

- The one-time addition of solid phase DARAMEND OE® in the bottom of the excavation areas prior to backfill materials placed in the saturated zone.

- Seasonal surface application recycled process water to the backfilled excavations to increase soil moisture and expedite the in-situ degradation of residual target constituents (as discussed in Section 5.2.4.3.2.2.).

The DGW permit application will be submitted following LSRP certification of this RAWP.

5.3.2 NJDEP – DLUR – Freshwater Wetlands/Flood Hazard Area

Proposed remedial activities were compared to the known extent of areas regulated by NJDEP – DLUR (i.e., freshwater wetlands, freshwater wetland transition areas, flood hazard areas, riparian zones). In accordance with NJDEP Freshwater Wetlands Protection Act Rules and Flood Hazard Area Control Act Rules, N.J.A.C. 7:7A and 7:13, a Freshwater Wetlands General Permit 4 (FWW GP4) and Flood Hazard Area Individual Permit (FHAIP) will be required to conduct remedial activities in these regulated areas.

The DLUR permit application submitted to NJDEP will include a discussion of the potential presence of bog turtle (*Chlemys muhlenbergii*), a state endangered and federally threatened species, and propose BMPs (e.g., active work area monitoring, exclusion fencing) to address the potential for TNT Project Area disturbances to influence bog turtle habitat.

The DLUR application can be submitted following LSRP certification of this RAWP.

5.3.3 MCSCD – Soil Erosion and Sediment Control Certification

A SESC Certification was issued by MCSCD for the TNT pilot study work. The certification was effective through 2018. Based on the extent of the proposed activities and disturbance of more than 5,000 square feet of excavated soil, approval of a SESCP by MCSCD is required. The SESCP will define the measures to be taken during project implementation to mitigate soil erosion and transport of soil or sediment. In addition, stormwater management during temporary construction (excavation) activities requires a Request for Authorization (RFA) under NJDEP Construction Activity Stormwater General Permit (5G3) through the NJDEP Bureau of Nonpoint Pollution Control. As such, an SESCP certification application will be submitted to MCSCD and an RFA for the 5G3 will be submitted via NJDEP's online permit program.

The MCSCD certification application can be submitted following final design.

5.3.4 Local Permits

The project will require local permits to be obtained by the selected remediation contractor. Local permit approvals may include, but are not limited to the following:

- Township/County – Site Plan Approval
- Township/County – Traffic Control: Howard Boulevard Entrance
- Township/County – Electrical Permit
- JCP&L – Electrical Drop Authorization

Local permit applications can be submitted following final design and/or as part of the selected contractor's pre-mobilization activities.

5.4 Documentation & Reporting

Hercules will generate data throughout the soil processing and bioremediation components of the project. Monthly progress reports will be submitted throughout the project summarizing active season material movement and processing quantities, as well as analytical data received. During the inactive season, monthly reports will document site inspections and any maintenance activities conducted. Monthly progress reports will be submitted to the LSRP and NJDEP.

The PCSP (**Appendix D**) establishes an annual reporting frequency where data will be summarized and interpreted in the context of remedial progress and attainment of remedial action objectives established in Section 4.4. Annual reports will be submitted to the LSRP and NJDEP,

and serve as the basis for annual project progress update meetings each spring. Hercules, the LSRP, and NJDEP will meet to discuss results and address any process modifications as part of an adaptive management and optimization approach.

Following the completion of ex-situ bioremediation activities (i.e., attainment of the NRDCSRS remedial action objective), Hercules will prepare a remedial action report (RAR) presenting actual operational quantities (volumes excavated, processed, and backfilled), process confirmation dataset, as-built extents of excavation areas, and other information relevant to the preceding active phase of the remedy. The RAR will include an application for a remedial action permit (RAP) to facilitate the long-term monitoring program. A LTMP will be appended to the RAR.

Consistent with NJDEP recommendations, the RAR will facilitate a discussion of the need for and development of a TNT Project Area-specific impact to groundwater soil remediation standard.

A restrictive covenant (i.e., deed notice) is required for the LSRP to issue a response action outcome (RAO). The deed notice will be Facility-wide or area-specific depending on timing of other remedial actions onsite beyond the TNT Project Area.

Section 6: Implementation Schedule

Appendix I presents a project implementation timeline. Implementation along this timeline is contingent upon receipt of permits and approvals, and contractor selection and availability.

As previously noted, the current excavation volume will require four processing cycles to treat the material. Section 3.2.4 indicates that potential target constituent source mass exists elsewhere onsite that will be delineated and assessed for incorporation into the TNT Project Area remedy. Based on current information, those volumes are considered negligible in the context of the overall excavation volume and is not expected to extend the project beyond four processing years.

AOC1	Environmental media - Media Soil, including soil vapor pore spaces	A-Line Area - Originally began operations as a storage area for dynamite products in the late 1800's. The area was repurposed in 1915 to produce smokeless gunpowder and maintained this usage until Facility closure in 1996.	Yes	RI	5/3/2016			Soil	Metals + PAHs	VO	Other	AOC Specific ARS and Remediation Standards	Ingestion/Dermal						The SI was conducted between 1998 and 2004 and approved by the NJDEP on June 27, 2005, Phase I RI was conducted between 2005 and 2007 and the Phase II RI was conducted in November 2013. Results from this AOC were combined with the results from other AOCs to complete the delineation of constituents of concern in soil.
AOC2	Environmental media - Media Soil, including soil vapor pore spaces	Ammonium Nitrate Area - This area was established in the late 1940's for the production of ammonium nitrate prills used in commercial blasting. This usage continued until the early 1970's when the process was moved to another facility.	Yes	RI	5/3/2016			Soil	Metals	PAHs	Other	AOC Specific ARS and Remediation Standards	Ingestion/Dermal						The SI was conducted between 1998 and 2004 and approved by the NJDEP on June 27, 2005, Phase I RI was conducted between 2005 and 2007 and the Phase II RI was conducted in November 2013. Results from this AOC were combined with the results from other AOCs to complete the delineation of constituents of concern in soil.
AOC3	Environmental media - Media Soil, including soil vapor pore spaces	B-Line Area - This area was established in 1915 to produce smokeless gunpowder and maintained this usage until Facility closure in 1996. This area also produced cast smokeless powder for use in small rockets during the cold war (circa mid 1950's through late 1980's)	Yes	RI	5/3/2016			Soil	Metals + PAHs	VO	Other	AOC Specific ARS and Remediation Standards	Ingestion/Dermal						The SI was conducted between 1998 and 2004 and approved by the NJDEP on June 27, 2005, Phase I RI was conducted between 2005 and 2007 and the Phase II RI was conducted in November 2013. Results from this AOC were combined with the results from other AOCs to complete the delineation of constituents of concern in soil.
AOC4	Environmental media - Media Soil, including soil vapor pore spaces	Development Area - Established in 1915 for research and quality control for the development and improvement of propellants/explosives. This function was maintained until Facility closure in 1996.	Yes	RI	5/3/2016			Soil	Metals + PCBs	PAHs	Other	AOC Specific ARS and Remediation Standards	Ingestion/Dermal						The SI was conducted between 1998 and 2004 and approved by the NJDEP on June 27, 2005, Phase I RI was conducted between 2005 and 2007 and the Phase II RI was conducted in November 2013. Results from this AOC were combined with the results from other AOCs to complete the delineation of constituents of concern in soil.
AOC5	Environmental media - Media Soil, including soil vapor pore spaces	Dynamite Area - Established in 1871 for the manufacture of dynamite. This usage continued until the production was phased out in 1971.	Yes	RAW	8/25/2020			Soil	Metals	PAHs	Other	AOC Specific ARS and Remediation Standards	Ingestion/Dermal		Excavation	Bioremediation	Monitored Natural Attenuation		The SI was conducted between 1998 and 2004 and approved by the NJDEP on June 27, 2005, Phase I RI was conducted between 2005 and 2007 and the Phase II RI was conducted in November 2013. Results from this AOC were combined with the results from other AOCs to complete the delineation of constituents of concern in soil. A portion of this AOC is being addressed as part of the TNT Project Area Soil Remedial Action Work Plan.
AOC6	Environmental media - Media Soil, including soil vapor pore spaces	Finishing Area - Established in 1915 for coating and packaging of smokeless powder. This usage was maintained until Facility closure in 1996.	Yes	RI	5/3/2016			Soil	Metals	PAHs	Other	AOC Specific ARS and Remediation Standards	Ingestion/Dermal						The SI was conducted between 1998 and 2004 and approved by the NJDEP on June 27, 2005, Phase I RI was conducted between 2005 and 2007 and the Phase II RI was conducted in November 2013. Results from this AOC were combined with the results from other AOCs to complete the delineation of constituents of concern in soil.
AOC7	Environmental media - Media Soil, including soil vapor pore spaces	Maintenance Area - Established in the late 1800's as a Facility support and repair area. This area also served as a power generation area beginning in approximately 1940. The area usage remained the same until Facility closure in 1996.	Yes	RI	5/3/2016			Soil	Metals + PCBs	VO + PAHs	Other	AOC Specific ARS and Remediation Standards	Ingestion/Dermal						The SI was conducted between 1998 and 2004 and approved by the NJDEP on June 27, 2005, Phase I RI was conducted between 2005 and 2007 and the Phase II RI was conducted in November 2013. Results from this AOC were combined with the results from other AOCs to complete the delineation of constituents of concern in soil.
AOC8	Environmental media - Media Soil, including soil vapor pore spaces	Miscellaneous Off-Site Areas - This area encompasses non utilized buffer zone property and activites not associated with manufacturing operations (i.e. groundwater supply, personnel housing, etc.)	Yes	RI	5/3/2016			Soil	PAHs	Metals	Other	AOC Specific ARS and Remediation Standards	Ingestion/Dermal						The SI was conducted between 1998 and 2004 and approved by the NJDEP on June 27, 2005, Phase I RI was conducted between 2005 and 2007 and the Phase II RI was conducted in November 2013. Results from this AOC were combined with the results from other AOCs to complete the delineation of constituents of concern in soil.
AOC9	Environmental media - Media Soil, including soil vapor pore spaces	Nitroglycerin Area - Established in 1871 for the manufacture of nitroglycerin used originally in dynamite and later smokeless powder production. The area usage remained the same until Facility closure in 1996.	Yes	RAW	8/25/2020			Soil	PAHs	Metals	Other	AOC Specific ARS and Remediation Standards	Ingestion/Dermal		Excavation	Bioremediation	Monitored Natural Attenuation		The SI was conducted between 1998 and 2004 and approved by the NJDEP on June 27, 2005, Phase I RI was conducted between 2005 and 2007 and the Phase II RI was conducted in November 2013. Results from this AOC were combined with the results from other AOCs to complete the delineation of constituents of concern in soil. A portion of this AOC is being addressed as part of the TNT Project Area Soil Remedial Action Work Plan.
AOC10	Environmental media - Media Soil, including soil vapor pore spaces	Storage Area - Established in 1915 for the storage and shipping of propellants and explosives manufactured at the Facility. This usage was maintained until Facility closure in 1996.	Yes	RI	5/3/2016			Soil	PAHs	Metals	Other	AOC Specific ARS and Remediation Standards	Ingestion/Dermal						The SI was conducted between 1998 and 2004 and approved by the NJDEP on June 27, 2005, Phase I RI was conducted between 2005 and 2007 and the Phase II RI was conducted in November 2013. Results from this AOC were combined with the results from other AOCs to complete the delineation of constituents of concern in soil.
AOC11	Environmental media - Media Soil, including soil vapor pore spaces	TNT Area - Established in 1917 to produce TNT for World War I. Production in this area ceased in approximately 1920 after World War I ended.	Yes	RAW	8/25/2020			Soil	PAHs	Metals	Other	AOC Specific ARS and Remediation Standards	Ingestion/Dermal		Excavation	Bioremediation	Monitored Natural Attenuation		The SI was conducted between 1998 and 2004 and approved by the NJDEP on June 27, 2005, Phase I RI was conducted between 2005 and 2007 and the Phase II RI was conducted in November 2013. Results from this AOC were combined with the results from other AOCs to complete the delineation of constituents of concern in soil. This AOC is being addressed as part of the TNT Project Area Soil Remedial Action Work Plan.

Section 1: Introduction

1.1 Overview

On behalf of Hercules LLC (Hercules), Kennedy/Jenks Consultants Inc. (KJ) prepared this Ecological Risk Assessment (ERA) as a component of the TNT Project Area Soil Remedial Action Work Plan (TNT RAWP) for the former Hercules Kenvil Works Facility, located on Hercules Road in Kenvil, Morris County, New Jersey (the Facility) (**Figure 1**). This ERA evaluates potential risks attributable to constituents in soil within the TNT Project Area (**Figure 2**). The TNT Project Area was excluded from the Ecological Evaluation/Ecological Risk Assessment (EE/ERA) presented with the Phase II Remedial Investigation Report (Phase II RIR) (Hercules 2016) in anticipation of supplemental data collection and active remediation. This ERA provides a comparison of potential risks under current and post-remedy conditions.

The remedial program at the Facility is coordinated through a licensed site remediation professional and conducted in accordance with the New Jersey Department of Environmental Protection's (NJDEP) Technical Requirements for Site Remediation (TRSR), New Jersey Administrative Code (N.J.A.C.) 7:26E. Consistent with NJDEP's Ecological Evaluation Technical Guidance (2015), ecological risk assessment activities were conducted in accordance with United States Environmental Protection Agency (USEPA) and other federal guidance, including Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments (USEPA 1997).

1.2 Background

The EE/ERA (Hercules 2016) separated the Facility into three general categories:

1. Areas where ecological risk is negligible.
2. Areas where ecological risk is uncertain and assessment is needed.
3. Areas where constituent concentrations and/or physical characteristics merit remediation (e.g., ecological risk likely), regardless of the outcome of the ecological risk assessment process (Areas of Presumed Remedial Action).

The EE/ERA included quantitative evaluation of areas in categories 1. and 2. Acknowledging the need for active remediation in the TNT Project Area (an area in category 3.), Hercules opted to address potential ecological risk in this area as a component of remedial design to ensure that the chosen remedy remained protective of both human health and the environment.

The EE/ERA relied on the site investigation/remedial investigation (SI/RI) dataset. Refined delineation data collection in the TNT Project Area supplements the SI/RI dataset, and is included in this evaluation to provide a comprehensive representation of existing conditions. The TNT Bioremediation Pilot Study (Pilot Study) (Hercules 2017) yielded data representative of post-remedy conditions in TNT Project Area soil and are used herein to assess potential exposure risks following remedy implementation.

Section 2: Hazard Identification

This ERA evaluates the comprehensive TNT Project Area characterization dataset (SI/RI and refined delineation) to identify constituents of potential ecological concern (COPECs). Consistent with the EE/ERA, the evaluation focuses on surface soil, considered to be 0 to 2 feet below ground surface (bgs) and includes any sample with all or a portion of its representative interval occurring above 2 feet bgs. **Exhibit 1** presents the TNT Project Area ERA dataset.

The proposed remedy outlined in the TNT RAWP focuses on the five nitroaromatic constituents listed below, collectively known as the target constituents.

- 2,4,6-Trinitrotoluene (TNT)
- 2-Amino-4,6-dinitrotoluene (2-ADNT)
- 4-Amino-2,6-dinitrotoluene (4-ADNT)
- 2,4-Dinitrotoluene (2,4-DNT)
- 2,6-Dinitrotoluene (2,6-DNT)

While these target constituents are the focus of the proposed remedy in the TNT Project Area, the ERA presented herein evaluates the full constituent suite included in the comprehensive TNT Project Area dataset.

2.1 Ecological Conceptual Site Model

Facility development, operations, and operational incidents served as historical sources and distributive processes by which constituents entered environmental media (primarily soil) at the Facility. Pre- and post-remedy exposure scenarios are similar, as the soil surface is currently accessible and is expected to remain as such following remediation.

2.1.1 Existing Conditions CSM

Process upsets and operational incidents released TNT and manufacturing intermediaries (i.e., 2,4-DNT and 2,6-DNT) to surface soil in the TNT Area. Reconstruction and renovation of the manufacturing area distributed TNT in surface soil beyond the location of initial release. TNT production ceased in 1919 and the TNT Area has remained inactive since 1923. Over time, erosion, dissolution, and degradation of TNT has occurred, resulting in the presence of TNT and its associated break down products (2-ADNT and 4-ADNT) in TNT Project Area soil and underlying groundwater.

2.1.2 Post-Remedy CSM

The overall remedial objective for TNT Project Area soil is target constituent source mass destruction to mitigate mass transfer from soil to groundwater. Remedial action aims to reduce target constituent concentrations to below their respective NJDEP non-residential direct contact soil remediation standards (NRDCSRS) via ex-situ bioremediation in engineered containment structures (i.e., biocells) prior to soil being returned to the excavations where additional biodegradation will occur. The TNT pilot study, on which the full-scale remedy is based, documented target constituent concentration reductions within treatment cells that achieved

greater than 95 percent target constituent mass reduction and attainment of NJDEP's residential direct contact soil remediation standards (RDCSRS). Post-study sampling documented additional reductions attributable to ongoing biodegradation after the active management study period. Pilot study results support the assessment of post-remediation conditions presented in this ERA.

Attachments 3 and 4 of the TNT RAWP present TNT pilot study and post-study results, respectively.

2.2 Identification of Constituents of Potential Ecological Concern

COPECs are identified via a comparison of generic ecological screening benchmarks (ESBs) to detected constituent concentrations in environmental media. Generic ESBs represent a threshold concentration that a majority of target organisms (e.g., plants, invertebrates) can tolerate and a concentration that may cause adverse effects in specific organism communities. Generally, ESBs were developed from various datasets that relate constituent concentrations in an environmental medium with occurrence of effects in sensitive species. Generic ESBs do not consider site-specific factors that may affect constituent bioavailability and toxicity (e.g., pH, organic carbon content).

Selection of ESBs for this ERA relied on those used in the EE/ERA (Hercules 2016). Consistent with the EE/ERA, preference was given to values presented in NJDEP's Ecological Screening Criteria table (2009). **Table 1** presents ESBs and associated sources.

Since the preparation of the EE/ERA, ESBs for target constituents have become available and/or been updated (USEPA 2018). The influence of these ESBs on the COPEC screen results are evaluated in a sensitivity analysis presented in Section 3.

2.2.1 Existing Conditions

Identification of COPECs under existing conditions relied on a sequential screening process using a conservative approach to avoid false negatives using risk-based EBSs and grounding the risk-based assessment of Facility conditions in the context of regional ambient soil characteristics.

First, the maximum concentration of each detected constituent was compared to its ESB to calculate a hazard quotient (HQ). All constituents with HQ_{max} greater than 1 or those lacking an ESB were retained for additional screening. Constituents were not retained if they were not detected (i.e., 0 detections), had a low frequency of detection (FoD) (i.e., less than 5 detections), or if the HQ_{max} was less than 1.

Retained constituents were evaluated via a comparison of a statistical representation (95 percent upper confidence limit of the mean [95UCL]) of the TNT Area dataset across the exposure area (i.e., TNT Area) to ESBs. ProUCL (Version 5.1.002) was used to calculate 95UCLs. Constituents with HQ_{95UCL} greater than one were retained as COPECs.

As noted in Section 2.2, ESBs are generic risk-based benchmarks. Metals identified as COPECs occur naturally in soil independent of Facility-related influences. New Jersey soils, including those in the Ridge and Valley physiographic province where the Facility is located, contain metals at ambient concentrations exceeding risk-based ESBs (Sanders 2003). As such, the 90th percentile concentration of TNT Project Area dataset metals was compared to the 90th percentile ambient metals concentrations in New Jersey (90AMCNJ) as reported by the Division of Science, Research & Technology (Sanders 2003) to differentiate between ambient conditions and Facility-related influences.

The following table summarizes constituents with HQ_{95UCL} greater than one retained as COPECs.

Chemical	FoD (%)	ESB	95UCL	HQ_{95UCL}	90th Percentile	90AMCNJ	COPEC (Y/N)	Rationale
Explosives (ug/kg)								
TNT	36	6,000	7,061,632	1,177	--	--	Y	HQ>1
2,4-DNT	13	1,280	493,049	385	--	--	Y	HQ>1
Nitrocellulose	40	65,000	1,624,355	25	--	--	N	See below
Metals (mg/kg)								
Aluminum	100	50	32317	646	35600	21080	N	See below
Antimony	30	0.27	1.52	6	3.15	0.42*	Y	HQ>1
Arsenic	98	9.9	21.05	2	17	7.32	Y	HQ>1
Chromium	100	0.4	19.47	49	23.02	21.2	N	See below
Cobalt	100	0.14	13.72	98	12.31	11.4	N	See below
Copper	100	5.4	1,634	303	46.56	26.04	Y	HQ>1
Lead	100	11	3,136	285	1547	54	Y	HQ>1
Manganese	100	220	499.4	2	578	1192	N	See below
Mercury	89	0.1	0.73	7	0.45	0.15	Y	HQ>1
Selenium	58	0.52	1.75	3	2.4	0.49*	Y	HQ>1
Vanadium	100	2	50.68	25	55.78	29.68	Y	HQ>1
Zinc	100	8.5	792.9	93	224.1	112.3	Y	HQ>1
SVOCs (ug/kg)								
2,4-DNT	31	1,280	11,556	9	--	--	Y	HQ>1
2,6-DNT	22	32.8	2,687	82	--	--	Y	HQ>1

* Value was reported non-detect; the listed value is the method detection limit (Sanders 2003)
ug/kg = micrograms per kilogram
mg/kg = milligrams per kilogram

Chromium, cobalt and manganese concentrations (95UCL) found in the TNT Project Area are less than or similar to regional (i.e., Ridge and Valley Province, rural) ambient metals concentrations. As such, these constituents do not merit further evaluation.

Consistent with the EE/ERA, aluminum is not retained as a COPEC based on soil pH. Specifically, the soluble fraction of aluminum in soil can pose a potential risk to ecological receptors; however, it is understood that solubility, and therefore bioavailability, is based on the measured pH of onsite soil. Potential ecological risks associated with aluminum are only expected to occur when soil pH is less than 5.5 (USEPA 2003). Available data indicates the pH in soil is 6 (**Table 2**). As such, aluminum does not merit further evaluation.

Nitrocellulose is a fibrous insoluble solid produced via the nitration of cotton. An ESB for nitrocellulose is unavailable. For the purposes of the screen (and consistency with the EE/ERA), this ERA used the nitroglycerin ESB as a surrogate for nitrocellulose. Per Ellis et al. (1980) and Williams et al. (2015), toxicology studies on nitrocellulose found that test subjects (i.e., mice, rats, and dogs) showed no toxicological effects when ingesting nitrocellulose in varied doses at levels exceeding 5 percent of body weight. These no effects concentrations are two orders of magnitude greater than the surrogate ESB used in the EE/ERA. Per Williams et al. (2015) nitrocellulose is considered non-toxic, and toxicity reference values were unable to be developed. Given this documented lack of toxicity, nitrocellulose does not merit further evaluation.

Table 2 summarizes the maximum detect, 95UCL, and 90AMCNJ COPEC screen results based on existing conditions data. **Exhibit 2** presents the ProUCL output files.

TNT Project Area COPECs based on existing conditions include:

- TNT
- 2,4-DNT
- 2,6-DNT
- Antimony
- Arsenic
- Copper
- Lead
- Mercury
- Selenium
- Vanadium
- Zinc

The following section evaluates the influence of TNT Project Area soil remedy implementation on both target constituents and metals listed as secondary/comingled COPECs above.

2.2.2 Post-Remedy Conditions

The TNT Project Area remedy focuses on target constituent mass reduction in soil. The TNT RAWP (Section 3) also acknowledges the presence of metals at concentrations that merit consideration in the remedial process, and evaluates these secondary/comingled constituents separately. Consistent with the approach outlined in the TNT RAWP, this evaluation of post-remedy conditions provides a forward-looking qualitative assessment of metals COPECs and a quantitative evaluation of target constituents.

2.2.2.1 Metals

Many locations in which the secondary COPECs (**Section 2.2.1**) are detected under existing conditions also coincide with excavation areas that are identified in the TNT RAWP for the purposes of target constituent remediation. Implementation of the proposed remedy outlined in the TNT RAWP will not remediate the secondary COPECs, but it will alter the nature and extent of comingled metals in soil and associated exposure conditions.

There is also an area on the east bank of the TNT Project Area boundary, surrounding the acid recovery building, in which metals are geographically concentrated. This area will remain relatively undisturbed throughout the TNT remediation process as there is only one excavation area found within this area (Figure 3). This area will be considered an Area of Presumed Remedial Action due to the likelihood that the geographically concentrated secondary COPECs merit remediation even after the proposed remedy outlined in the TNT RAWP treats target constituents.

As such, post-scenario risk will be reevaluated within the TNT Project Area following remedy implementation and the secondary COPECs as well as the Area of Presumed Remedial Action will be targeted for remediation at that time, if necessary.

2.2.2.2 Target Constituents

Pilot study data indicates that bioremediation conducted in the treatment cells will reduce target constituent concentrations to their respective RDCSRS. This treated material will then be placed back into the excavations where ecological exposures could occur as long-term biodegradation further reduces target constituent concentrations. **Appendix G** to the TNT RAWP defines a series of excavation areas where target constituent concentrations in soil will be reduced to at or below RDCSRS.

To assess post-remedy conditions, target constituent RDCSRS (used to define excavation extents and consistent with pilot study results) were used as surrogate COPEC concentrations for samples within target excavation areas. Constituent concentrations beyond the excavation areas remain consistent with existing conditions. 95UCLs were calculated for target constituents retained as COPECs in Section 2.2.1. The 95UCL was then compared to ESB to calculate HQs for each of the three COPECs. **Table 3** summarizes the RDCSRS and 95UCL COPEC screen results based on post-remedy conditions data. **Exhibit 3** presents the ProUCL output files.

The following table summarizes this comparison.

Chemical	FoD (%)	Range of Detects (µg/kg)	Arithmetic Mean (µg/kg)	ESB (µg/kg)	95 UCL (µg/kg)	HQ_{95UCL}	COPEC (Y/N)	Rationale
Explosives								
TNT	36%	85 - 21000	2690	6000	4162	0.69	N	HQ<1
2,4-DNT	16%	110 - 700	112	1280	129.7	0.1	N	HQ<1
SVOCs								
2,4-DNT	33%	26 - 700	249	1280	246.1	0.19	N	HQ<1
2,6-DNT	25%	21 - 700	209	32.8	178.6	5	Y	HQ>1

Based on this assessment, potential risk to TNT and 2,4-DNT is unlikely, while risks attributable to 2,6-DNT is possible, but unlikely. The information below provides greater context related to potential risk associated with 2,6-DNT in post-remedy soil.

The post-study dataset relied on the RDCSRS (700 µg/kg) for 2,6-DNT surrogate data. Pilot study sampling results for 2,6-DNT at the conclusion of the study range from 235 to 300 µg/kg, indicating that the use of the RDCSRS is overly conservative (i.e., more than twice the highest detected 2,6-DNT concentration). Further reductions in 2,6-DNT concentrations were observed during post-study monitoring, where 2,6-DNT was detected in less than 17 percent of the samples at an average detected concentration less than 200 µg/kg.

Pilot study and post-study 2,6-DNT sample reporting limits (51 to 420 µg/kg) exceed its ESB (32.8 µg/kg). 2,6-DNT was not detected in the majority (67 percent) of samples collected from study trials representative of the proposed remedy during the last two pilot study sampling events and subsequent post-study events. Method detection limits for non-detect samples during these

events ranged from 23 to 140 µg/kg, demonstrating the laboratory's ability to detect and report 2,6-DNT at estimated concentrations at or below the ESB. The absence of 2,6-DNT in quantifiable concentrations provides an indication that potential risk (HQ) may be overestimated.

Section 3: Sensitivity Analysis

As noted, ESBs used in the evaluation presented in Section 2 are consistent with those used in the EE/ERA (Hercules 2016). Subsequent to EE/ERA preparation, USEPA Region 4 updated its ESBs, including values used in the EE/ERA (2003) specific to the target constituents evaluated herein. A sensitivity analysis was performed using the updated (2018) USEPA Region 4 ESBs to understand the influence of the updates on the COPEC selection process. This sensitivity analysis addresses TNT Project Area target constituents previously identified as COPECs under existing conditions and analyzes them under post-remedy conditions (**Section 2.2.1**).

The following table compares ESBs used in Section 2 to USEPA Region 4 (2018) benchmarks used in this sensitivity analysis.

CAS Number	Chemical	ESB (USEPA 2003) (µg/kg)	ESB (USEPA 2015) (µg/kg)
118-96-7	TNT	6,000	7,500
121-14-2	2,4-DNT	1,280	6,000
606-20-2	2,6-DNT	32.8	4,000

As shown in the table above, ESBs increased for all constituents addressed in this sensitivity analysis. A comparison of 2003 to 2018 USEPA Region 4 ESBs for explosive and energetic constituents identified order-of-magnitude decreases for four non-target constituents (1,3-dinitrobenzene, HMX, RDX, and tetryl). These changes do not alter the outcome of the existing conditions data screen.

This sensitivity analysis relies on the comprehensive TNT Project Area dataset and post-remedy surrogate data, screening process, and 95UCL calculation software detailed in Section 2. The following table summarizes target constituent post-remedy data screened against the USEPA (2018) ESBs.

Chemical	FoD (%)	Range of Detects (µg/kg)	Arithmetic Mean (µg/kg)	ESB (µg/kg)	95 UCL (µg/kg)	HQ_{95UCL}	COPEC (Y/N)	Rationale
Explosives								
TNT	36%	85 – 21,000	2690	7,500	4162	0.55	N	HQ<1
2,4-DNT	16%	110 - 700	112	6,000	129.7	0.1	N	HQ<1
SVOCs								
2,4-DNT	33%	26 – 700	249	6,000	246.1	0.19	N	HQ<1
2,6-DNT	25%	21 - 700	209	4,000	178.6	0.04	N	HQ<1

As illustrated in the preceding table, target constituents in the TNT Project Area do not pose unacceptable ecological risks to receptors following remedy implementation. These results are consistent with those presented for target constituents under post-remedy conditions, with the exception of 2,6-DNT (**Section 2.2.2**).

As noted, USEPA Region 4 (2003) provided the 2,6-DNT ESB used in the EE/ERA. The 2018 ESB used in this sensitivity analysis supersedes and replaces the 2003 value. The results of this evaluation indicate that potential risk attributable to target constituents is unlikely under post-remedy conditions. As such, no further ecological evaluation of target constituents is warranted.

Table 4 summarizes the COPEC screen results based on post-remedy conditions data. **Exhibit 3** presents the ProUCL output files.

Section 4: Risk Characterization and Conclusions

This ERA technical appendix evaluates existing and post-remedy conditions in the TNT Project Area and demonstrates that:

- The remedy outlined in the RAWP is protective of ecological receptors exposed to target constituents in TNT Project Area soil
- Potential risk attributable to a suite of metals present in the TNT Project Area remains uncertain, and remedy implementation will influence exposure scenarios and data distribution.

Based on these findings, no additional ecological evaluation is necessary for target constituents, and attaining remedial action objectives will result in conditions protective of ecological receptors.

Ecological risk attributable to metals will be reevaluated following remedy implementation. Evaluation results will be assessed in conjunction with the results of the re-evaluation of metals in TNT Project Area soil for human health endpoint discussed in the TNT RAWP (Section 3.3.1 and Appendix C) and future use of the Facility to identify the need for additional remediation in this area.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

nu hat (MLE)	364.5	nu star (bias corrected)	361.3
Mean (detects)	11.83		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	11.64

Suggested UCL to Use

95% Chebyshev (Mean, Sd) UCL	3136

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Manganese

General Statistics

Total Number of Observations	7	Number of Distinct Observations	7
		Number of Missing Observations	258
Minimum	178	Mean	372.9
Maximum	633	Median	366
SD	172.4	Std. Error of Mean	65.14
Coefficient of Variation	0.462	Skewness	0.336

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest.
For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Section 1: Introduction

On behalf of Hercules LLC (Hercules), Kennedy/Jenks Consultants Inc. (KJ) prepared this TNT Refined Delineation Technical Memorandum (TRDTM) summarizing the results of refined delineation activities outlined in the *TNT Refined Delineation Work Plan* (TRDWP) (Hercules 2017) at the Hercules Kenvil Works Facility, located in Kenvil, Morris County, New Jersey (the Facility) (**Figure 1**). Activities described herein focused on refining delineation of 2,4,6-trinitrotoluene (TNT), 2,4-dinitrotoluene (DNT), 2,6-DNT, 2-amino-4,6-DNT (2ADNT), and 4-amino-2,6-DNT (4ADNT) in soil (hereafter collectively referred to as target constituents) within an area encompassing approximately 80 acres in the southwestern portion of the Facility (TNT Project Area). This TRDTM supports the TNT Area Soil Remedial Action Work Plan (TNT RAWP) and establishes a basis for the remedial excavation planning.

The remainder of this memorandum summarizes field sampling activities, presents sample analytical results, and updates constituent-specific delineation drawings presented in the Phase II Remedial Investigation Report (Phase II RIR) (Hercules 2016).

1.1 Overview

Hercules acknowledged the need for active remediation of TNT early in the Site Investigation/Remedial Investigation (SI/RI) process and initiated a remedial alternatives evaluation to identify potentially applicable approaches given conditions in the TNT Area (e.g., crystalline TNT particles of various size entrained in surface and shallow subsurface soil). Hercules identified ex-situ bioremediation as an effective, implementable approach to address target constituents (see Section 4 of the TNT RAWP).

Remedial design and planning required an understanding of the total volume of soil requiring treatment via bioremediation. The TRDWP outlined an iterative, stepwise process to improve the resolution of the macroscale delineation presented in the SI/RI to support TNT Area soil remedial design activities. Consistent with the SI/RI, refined delineation targeted the most stringent criterion from NJDEP's non-residential direct contact soil remediation standard (NRDCSRS), residential direct contact soil remediation standard (RDCSRS), and impact to groundwater soil remediation standard (IGWSRS). For target constituents, the default IGWSRS are the most stringent criterion. **Table 1** summarizes applicable criteria for target constituents.

Refined delineation sampling occurred over two field events, Fall 2017 (Section 2.1) and Spring 2019 (Section 2.3). Following 2017 field sampling, Hercules conducted supplemental soil sampling to support development of site-specific IGWSRS for target constituents, and attended a technical consultation with New Jersey Department of Environmental Protection (NJDEP) staff regarding site-specific IGWSRS methods, and the role that site-specific IGWSRS would play in the remedial administrative process given the presence of target constituents in groundwater (Section 2.2). NJDEP indicated that the model for developing site-specific IGWSRS was not built to address constituents with relatively low solubility and mobility (i.e., TNT). Given that target constituents are currently found in groundwater underlying soil source areas, NJDEP recommended proceeding with the ex-situ bioremediation focused on addressing source mass removal and attaining applicable direct contact soil remediation standards. Following source mass removal to mitigate target constituent mass transfer to groundwater, and post-remediation soil and groundwater sampling, development of a site-specific IGWSRS would be appropriate. To this

end, refined delineation activities performed in 2019 focused on finalizing delineation to RDCSRS (the more stringent of the direct contact SRS for target constituents) in a number of areas.

The following sections summarize 2017 and 2019 sampling event results.

Section 2: Refined Delineation Activities

2.1 Refined Delineation Sampling - 2017

Target constituent criteria-specific isoconcentration contours presented in the SI/RI (**Exhibit 1**) identified approximately 109 acres exceeding NJDEP default IGWSRS for target constituents in and proximate to the TNT Project Area. TRDWP sampling focused on refining delineation within these areas.

KJ field staff and a Pace Analytical (Pace) mobile laboratory unit and laboratory technician mobilized to the Facility to begin refined delineation in October 2017. Refined delineation investigation locations were selected based on SI/RI data and field-identified step-out locations. Test pit excavation and preliminary soil screening were conducted as outlined in the TRDWP and repeated until areas were delineated vertically and horizontally to IGWSRS[1]. At each location, field personnel screened test pit sidewalls/bottom visually for signs of crystalline TNT and using an explosive detection field test kit (Expray®) and followed the iterative process for analytical sampling and/or establishment of step-out locations as outlined in the TRDWP.

Over the course of 30 field days, the team screened 180 test pits in accordance with the stepwise process outlined in the TRDWP (Hercules 2017) and collected 565 samples. Samples were submitted to Pace under chain-of-custody procedures, and a subset of samples authorized for Nitroaromatics and Nitramines (energetics and explosives [E&E]) analysis by United States Environmental Protection Agency (USEPA) SW846 Method 8095. Remaining samples were held as contingency samples. Upon receipt of analytical results, KJ reviewed the data and authorized contingency sample analysis until achieving delineation. Following data evaluation, KJ collected additional samples in December 2017 that were submitted to Pace's fixed laboratory in Madison, Wisconsin for analysis via USEPA SW846 Method 8095.

Exhibit 2 presents test pit logs and soil screening results. **Table 1** presents analytical sample results. **Exhibit 3** presents laboratory analytical data packages. Electronic data deliverables (EDDs) corresponding to the TRDWP data were generated in NJDEP's HAZSITE format, checked for errors using NJDEP's Electronic Data Submission Application (EDSA) (Version 7.1.5; Last updated September 2016), and submitted electronically to NJDEP via email. **Exhibit 4** presents a confirmation email that EDDs were successfully uploaded to NJDEP's database.

2017 refined delineation sampling distilled the 109-acre SI/RI delineation down to 22 discrete areas covering approximately 9 acres where target constituents exceed their respective default IGWSRS (**Figure 7**).

[1] In certain circumstances field sampling did not achieve delineation to IGWSRS due to field conditions and/or the capabilities of the sampling methods (e.g., mechanical limitations of excavator).

A summary of findings by area follows.

- **Area A** – Horizontal and vertical delineation of target constituents to default IGWSRS complete.

- **Area B** – Horizontal and vertical delineation of target constituents to default IGWSRS complete.

- **Area C** – Horizontal and vertical delineation of target constituents to default IGWSRS complete.

- **Area D** – Historical samples with TNT less than 1 mg/kg but above 0.2 mg/kg (IGWSRS), existing dataset provides sufficient resolution for excavation planning and remedy implementation.

- **Area E** – Horizontal and vertical delineation of target constituents to default IGWSRS complete.

- **Area F** – Horizontal and vertical delineation of target constituents to default IGWSRS complete.

- **Area G** – Delineation samples with TNT at concentration less than 1 mg/kg but above 0.2 mg/kg (IGWSRS), existing dataset provides sufficient resolution for excavation planning and remedy implementation.

- **Area H** – Horizontal and vertical delineation of target constituents to default IGWSRS complete.

- **Area I** – Horizontal and vertical delineation of target constituents to default IGWSRS complete.

- **Area J** – Horizontal and vertical delineation of target constituents to default IGWSRS complete.

- **Area K** – Horizontal delineation complete, groundwater infiltration and excavation sidewall instability precluded vertical delineation at certain interior sample locations.

- **Area L** – Horizontal and vertical delineation of target constituents to default IGWSRS complete.

- **Area M -** Horizontal and vertical delineation of target constituents to default IGWSRS complete.

- **Area N** – Horizontal and vertical delineation samples less than 1 mg/kg for TNT but greater than 0.2 mg/kg (IGWSRS), existing dataset provides sufficient resolution for excavation planning and remedy implementation.

- **Area O** – Vertical delineation samples less than 1 mg/kg for TNT but greater than 0.2 mg/kg (IGWSRS), existing dataset provides sufficient resolution for excavation planning and remedy implementation.

- **Area P** – Historical samples less than 1 mg/kg for TNT but greater than 0.2 mg/kg (IGWSRS), existing dataset provides sufficient resolution for excavation planning and remedy implementation.

- **Area Q** – Vertical delineation samples less than 1 mg/kg for TNT but greater than 0.2 mg/kg (IGWSRS), existing dataset provides sufficient resolution for excavation planning and remedy implementation.

- **Area R** – Vertical delineation incomplete at interior vertical confirmation sample location due to excavation sidewall instability and intrusion of groundwater. Sample location accessibility precluded horizontal delineation to IGWSRS at certain locations.

- **Area S** – Vertical delineation to IGWSRS not achieved prior to encountering the groundwater table; vertical delineation to RDCSRS achieved. A horizontal delineation sample less than 1 mg/kg for TNT but greater than 0.2 mg/kg (IGWSRS), existing dataset provides sufficient resolution for excavation planning and remedy implementation.

- **Area T** – Horizontal and vertical delineation of target constituents to default IGWSRS complete.

- **Area U** – Delineation samples less than 1 mg/kg for TNT but greater than 0.2 mg/kg (IGWSRS), existing dataset provides sufficient resolution for excavation planning and remedy implementation.

- **Area V** – Positive field screening results at horizontal delineation sample location, sample location inaccessibility precluded step-out location. Delineation samples less than 1 mg/kg for TNT but greater than 0.2 mg/kg (IGWSRS), existing dataset provides sufficient resolution for excavation planning and remedy implementation.

2.2 NJDEP Technical Consultation on Site-Specific IGWSRS

On December 5, 2018, representatives of NJDEP and Hercules met to discuss the technical scope, regulatory approach, and site-specific remediation goals associated with the bioremediation remedy in the TNT Project Area. When discussing the potential use of the SESOIL/AT123D model outlined in NJDEP's guidance (2014) to estimate TNT migration over time, NJDEP indicated that while TNT is soluble, its physiochemical properties cause it to move through the vadose zone and into groundwater at a rate well below that of volatile organic compounds for which the model was developed, and that the model is not the appropriate tool for developing a site-specific IGWSRS for TNT.

In light of that information, the remaining discussion focused on where and how site-specific IGWSRS for target constituents will influence the technical and administrative paths to closure. NJDEP noted the reduced reliance on site-specific IGWSRS in instances where groundwater contamination already exists, such as this case. NJDEP and Hercules agreed that the existing data are sufficient to support development of a remedial action work plan, and that following active remediation of soil and monitoring of concentration trends in groundwater, Hercules will consult with NJDEP regarding development of a post-remediation site-specific IGWSRS. **Exhibit 5** provides the technical consultation meeting minutes and summary memorandum.

2.2.1 Refined Delineation – Data Re-Evaluation

Based on the outcome of the technical consultation, delineation to RDCSRS (rather than IGWSRS) will guide remedy design and implementation. As such, KJ re-evaluated the comprehensive dataset (SI/RI and 2017 refined delineation data) to identify areas where delineation is complete to RDCSRS, opportunities to reduce the delineation extents, and supplemental sampling needs (data gaps).

The evaluation identified 20 of 22 areas delineated to RDCSRS. The two remaining areas (Areas R and V) required additional sampling to complete vertical and/or horizontal delineation to RDCSRS. Sampling to confirm target constituent concentrations at historical sample locations in two areas (Areas F and H) and to reduce delineation boundaries in two areas (Areas L and T) was also recommended. Supplemental sampling in these areas occurred in spring 2019.

2.3 Refined Delineation Sampling - 2019

In April 2019, field personnel conducted additional sampling at the six areas listed in Section 2.2.1. Nine soil boring locations were selected in these six areas, as follows:

- **Area F** – 1 historical confirmation location
- **Area H** – 1 historical confirmation location
- **Area L** – 2 horizontal delineation locations
- **Area R** – 1 horizontal delineation location
- **Area T** – 2 horizontal delineation locations
- **Area V** – 2 horizontal delineation locations

Soil borings were advanced via track-mounted Geoprobe at each location in Areas F, H, L, R, and T. Hand-driven cores were collected in Area V due to conditions inaccessible by Geoprobe equipment. Soil cores were screened consistent with the test pit screening procedures outlined in the TRDWP, and step-out boring locations selected accordingly. Forty-seven samples were collected and submitted to Pace for E&E analysis consistent with 2017 procedures.

Exhibit 2 presents boring logs and soil screening results. **Table 1** presents analytical sample results. **Exhibit 3** presents Pace analytical data packages. Electronic data deliverables (EDDs) corresponding to the TRDWP data were generated in NJDEP's HAZSITE format, checked for errors using NJDEP's Electronic Data Submission Application (EDSA) (Version 7.1.5; Last updated September 2016), and submitted electronically to NJDEP via email. **Exhibit 4** presents a confirmation email that EDDs were successfully uploaded to NJDEP.

Soil sample analytical results from the six areas sampled indicate:

- **Area F** – Historical sample results confirmed.

- **Area H** – Historical sample results not confirmed, confirmation sample did not contain target constituents at concentrations greater than RDCSRS.

- **Area L** – Horizontal delineation to RDCSRS complete and delineation boundary adjusted to reduce areal extent.

- **Area R** – Horizontal delineation to RDCSRS complete.

- **Area T** – Horizontal delineation to RDCSRS complete and delineation boundary adjusted to reduce areal extent.

- **Area V** – Horizontal delineation to RDCSRS complete.

Based on these results, delineation is complete and no additional sampling is necessary.

Section 3: Data Usability Evaluation

Prior to preparing the TNT RAWP, KJ evaluated refined delineation soil sample laboratory data in the context of NJDEP's Data Quality Assessment and Data Usability Evaluation Technical Guidance (2014). The evaluation includes a review of case narrative information, holding times, and Quality Assurance and Quality Control (QA/QC) analyses for E&E compounds. **Exhibit 3** provides Pace's Level II analytical laboratory data packages.

Samples were collected and submitted to Pace's mobile and/or fixed laboratory. Samples were analyzed for E&E by USEPA SW846 Method 8095. EPA Method 8095 incorporates the use of gas chromatography/nitrogen phosphorous detection (GC/NPD) and gas chromatography/ electron capture detector (GC/ECD) techniques as an improvement over high-performance liquid chromatography (HPLC) separation techniques used in EPA Method 8330. GC/NPD and GC/ECD techniques improve the selectivity of Method 8095 and eliminate potential interferences that are common in Method 8330. Due to the advantages provided by EPA Method 8095 and its ability to be run in a mobile laboratory, this method was selected for use during refined delineation over the historically used Method 8330.

Lab analysis methods were conducted in accordance with the Pace Analytical ECCS Mobile Lab Services' Standard Operating Procedures. NJDEP does not provide specific guidance or protocols for Method 8095 (or other E&E methods) in its Data of Known Quality Protocols Technical Guidance (DKQP; NJDEP 2014). Consistent with DKQP guidance in the absence of a specific protocol, equivalent QC data was collected and analyzed.

Field QC samples were collected in accordance with the AQAPP (draft; Hercules, 2018) at the frequency noted below. Field blank analytical results are presented in **Table 2**.

Field QC Sample	Frequency
Blind Duplicate	1 sample per 20 samples
Matrix Spike/Matrix Spike Duplicate	1 sample per 20 samples
Field Blank (Equipment Rinsate Blank)	1 sample per day

Laboratory blanks and control samples were prepared at an equivalent frequency as outlined in Pace's Method Summary and Standard Operating Procedures.

KJ noted the following during the data usability evaluation:

- Where internal standards were outside QC limits, the data were qualified as estimated ("J" qualifier) by the laboratory.
- A comparison of blind duplicate samples to their parent samples showed that concentrations were similar.
- E&E were detected in 4 of the 28 field blanks collected during refined delineation.
- No tentatively identified compounds (TICs) were identified.
- The reporting limit (RL) for all compounds was 100 micrograms per kilogram.

Sample submission and management processes varied slightly between the mobile and fixed laboratory. As such, these elements are discussed separately below.

Onsite Mobile Laboratory

The mobile laboratory provided 24-hour turn-around times, allowing for prompt decision making regarding additional field sample collection and contingency sample analysis authorizations. Given the rapid turn-around and prompt decision making, samples were analyzed within required holding times.

A total of 438 soil samples and 26 water samples were analyzed by the mobile laboratory. The following table summarizes the outcomes of the quality control analyses performed by the mobile lab:

Initial Calibration	Initial calibrations were prepared using method specified number of points. The calibration was verified using a single point second source standard. Method calibration criteria were acceptable.
Continuing Calibration	The instrument calibration was verified every 10 samples using a single point calibration standard. Method criteria were acceptable for all constituents of concern over the course of the project, except where qualified.
Method Blanks	The method blanks that were analyzed each day were free of contamination.
Blank Spikes	The recoveries for the constituents of concern were acceptable, except where qualified.
MS/MSD	Method criteria were acceptable for all constituents of concern over the course of the projects, except where qualified.

Madison WI Laboratory

A total of 166 samples were sent to Pace Analytical laboratory in Madison, WI. The case narrative provided by the laboratory noted that samples were received in acceptable condition and met quality criteria outlined above except where qualified. Samples that were not placed on hold were extracted and analyzed within applicable holding times, held samples were frozen upon arrival to arrest hold times.

Based on review of the information provided by Pace, the data are appropriate for use in remedial design and subsequent actions.

Section 4: Results & Conclusions

Refined delineation activities provide a greater understanding of the extent of target constituents within the TNT Project Area at a resolution appropriate for remedial design and excavation planning. The following table compares SI/RI delineation to refined delineation results in the context of remediation standards.

Remediation Standard	SI/RI Delineation	Refined Delineation	Reduction
IGWSRS	109 Ac	9 Ac	100 Ac (92%)
RDCSRS	28 Ac	6.5 Ac	21.5 Ac (77%)

Ac – acres
% - percent reduction

Figures 2 through 6 illustrate sample analytical results for each of the five target constituents. Given the size of the Facility, sample density, and volume of data generated at each sample location, Facility-specific data presentation schemes developed for the Phase II RIR (Hercules 2016) were used to provide a useful visual tool for the reader while fulfilling the fundamental intent of the TRSR.

Figure 7 illustrates the delineated boundaries of target constituents (evaluated collectively) and includes information from both laboratory analytical data as well as field screening (visual observations and Expray® test kit results). These boundaries support remedial design and excavation planning activities outlined in the TNT RAWP.

NOTES.

1. THESE FILES ARE IN THE NORTH AMERICAN DATUM 19□3 NEW JERSEY STATE PLANE COORDINATE SYSTEM. THE TOPOGRAPHIC FILE REFERENCES THE NORTH AMERICAN VERTICAL DATUM 19□□. THE FACILITY GRID SYSTEM WAS HISTORICALLY DEVELOPED BY HERCULES INCORPORATED TO AID SITE MANAGEMENT, AND THE GRID LINES ARE NOT ORIENTED NORTH.
2. THE BOUNDARY LINE AS DELINEATED IS APPRO□IMATE AND HAS BEEN DIGIT□ED FROM A MAP ENTITLED "HERCULES INCORPORATED, KENVIL PLANT PROPERTY MAP, PLANT 0.10, ACCOUNT 9500, CLASSIFICATION 21045, FILE CODE 5WE REVISION 1" REVISED TO JUNE 11, 1970 PROVIDED BY REPRESENTATIVES OF HERCULES, INC., AND THE TA□ MAP OF THE TOWNSHIP OF RO□BURY AND NOT FROM AN ACTUAL FIELD SURVEY OR WITH THE BENEFIT OF A TITLE SEARCH.
3. PHASE II RI SOIL INVESTIGATION SAMPLE LOCATIONS WERE SELECTED BASED ANALYTICAL RESULTS PRESENTED IN THE SOIL SITE INVESTIGATION REPORT .MWH, 2004□AND THE SOIL REMEDIAL INVESTIGATION REPORT .MWH, 2007□.
4. SOIL ANALYTICAL SAMPLE RESULTS WERE COMPARED TO CRITERIA DERIVED FROM THE FOLLOWING APPLICABLE SOURCES: NJDEP RESIDENTIAL DIRECT CONTACT SOIL REMEDIATION STANDARDS .RDCSRS□;NON-RESIDENTIAL DIRECT CONTACT SOIL REMEDIATION STANDARDS .NRDCSRS□;AND IMPACT TO GROUNDWATER SOIL SCREENING LEVELS .IGWSSL□; SITE SPECIFIC SCREENING LEVELS PROVIDED BY NJDEP TO HERCULES IN THE JUNE 13, 2003 CORRESPONDENCE AND□SITE SPECIFIC SRS/SSL DEVELOPED BY OBG AND APPROVED BY THE LSRP.
5. ANALYTICAL SAMPLES PRESENTED ON THIS FIGURE WERE COLLECTED DURING THE SITE AND REMEDIAL INVESTIGATIONS. THE HIGHER CONCENTRATION IS PRESENTED FOR MULTIPLE DEPTH SAMPLES.
6. THE RESIDENTIAL DIRECT CONTACT SOIL REMEDIATION STANDARD .RDCSRS□:FOR 2,4,6-TRINITROTOLUENE IS 21 mg/□g, THE NON-RESIDENTIAL DIRECT CONTACT SOIL REMEDIATION STANDARD .NRDCSRS□:IS 95 mg/□g □N.J.A.C. 7:26D□:DEFAULT IMPACT TO GROUNDWATER SOIL SCREENING LEVELS IS 0.2 mg/□g .NJDEP□.
7. SOLID BROWN LINES REPRESENT DRY STREAM SEGMENTS OR FORMER DITCHES THAT NO LONGER CONVEY WATER SINCE MANUFACTURING OPERATIONS HAVE CEASED. THESE AREAS ARE NO LONGER CONSIDERED SURFACE WATER OR SEDIMENT BODIES AND ARE CONSIDERED SOIL IN THE REMEDIAL INVESTIGATION REPORT.
8. □ DASHED BROWN LINES REPRESENT STREAM SEGMENTS OR AREAS WITHOUT SUFFICIENT WATER PRESENT FOR SURFACE WATER SAMPLE COLLECTION, HOWEVER SATURATED SEDIMENTS ARE PRESENT.
9. HORI□ONTAL LIMITS OF CONSTITUENTS ANTICIPATED TO BE PRESENT AT CONCENTRATIONS E□CEEDING THE SRS/SSL ON AREAL E□TENT FIGURES ARE INFERRED BASED ON LOCATIONS WHERE CONSTITUENTS E□CEED THE SRS/SSL BY ANALYTICAL GROUP. THE HORI□ONTAL LIMITS OF CONSTITUENTS ANTICIPATED TO BE PRESENT AT CONCENTRATIONS E□CEEDING THE SRS/SSL ON FEC FIGURES ARE BASED ON LOCATIONS WHERE CONSTITUENTS E□CEED THE SRS/SSL AND LOCATIONS WHERE 1/2 THE PRACTICAL QUANTITATION LIMIT .PQL□E□CEED THE SCC. THEREFORE, SINCE THE FEC FIGURES TAKE A MORE CONSERVATIVE APPROACH .USING 1/2 THE PQL□THAN THE AREAL E□TENT FIGURES IN DEFINING THE HORI□ONTAL LIMITS, THE ANTICIPATED AREAS WHERE CONSTITUENTS ARE BELIEVED TO BE PRESENT AT CONCENTRATIONS E□CEEDING THE SRS/SSL ON THE AREAL E□TENT FIGURES WILL BE SMALLER THAN THE COMBINED AREAS FROM THE FEC FIGURES FOR A GIVEN ANALYTICAL GROUP.
10. THIS PLAN IS ADAPTED FROM APRIL 2007 REMEDIAL INVESTIGATION REPORT PREPARED BY MWH AMERICAS, INC.

Pace Analytical®
Mobile Lab Services

Mobile Lab Project Case Narrative

Report Date	December 1, 2017
Client	Kennedy/Jenks
Site/ Project Name	Hercules Inc. – Kenvil Works Facility
Location	Kenvil, NJ
Dates of Service	Oct 4 – Nov 7, 2017
Test Method Reference	LAM-018 Nitroaromatics by 8095
Pace Project Number	2769
Client Project or PO Number	1540001*36

1. Introduction

Pace Analytical – Mobile Lab Services (Pace) mobilized to the referenced site to provide analytical chemistry support during site investigation activities. The target analytes for the project were a client supplied list of nitroaromatics. The laboratory analyzed 438 soil samples and 26 water samples while on site. All method holding times were met. The Pace Lead Chemist was Christopher Munz and the Pace Project Manager was Nick Nigro.

2. Pace Method Summary

- Samples were analyzed for the client specified list of nitroaromatics in accordance with the Pace standard operating procedures (SOP) listed above.
- Soil samples were submitted in 4 oz jars. Samples that were not placed on hold were extracted immediately upon receipt and analyzed in less than 24 hours.
- The rinsate samples were received in 500 mL amber glass bottles. Samples were then immediately logged in on Pace chain of custody (COC).
- Nitroaromatics analysis was performed on an HP5890A GC equipped with an electron capture detector (ECD) and Agilent Chemstation for data processing.
- The reporting limit (RL) for all compounds was 100 µg/kg.
- Surrogate compounds were added to all samples prior to extraction.
- A laboratory blank and laboratory control sample (blank spike) were prepared on a daily basis or with every 20 samples. Matrix spike/matrix spike duplicate (MS/MSD) samples were prepared, extracted and analyzed using separate soil subsamples from the same parent sample bottle. Fortification of laboratory control and MS/MSD samples with target analytes occurred prior to sample extraction.
- All detections were confirmed in accordance with the Pace SOP using a second column.

3. Quality Control Summary

Initial Calibration	Initial calibrations were prepared using method specified number of points. The calibration was verified using a single point second source standard. Method calibration criteria were acceptable.
Continuing Calibration	The instrument calibration was verified every 10 samples using a single point calibration standard. Method criteria were acceptable for all constituents of concern over the course of the project, except where qualified.
Method Blanks	The method blanks that were analyzed each day were free of contamination.
Blank Spikes	The recoveries for the constituents of concern were acceptable, except where qualified.
MS/MSD	Method criteria were acceptable for all constituents of concern over the course of the project, except where qualified.

4. Analytical Reports

All field-generated draft results were confirmed through the standard Pace review process and one change was identified, as noted below. Draft results were reported on a dry weight basis.

Sample ID	Description	Analyte	Draft Result	Final Result
K174301-12	C11-7-02(03.0-03.5)	2,4-Dinitrotoluene	<120 ug/kg	240 ug/kg

Following is a listing of the appendices to this report:

- A – All analytical results in detailed format, including associated QC
- B – Chain of Custody Documentation

5. Signature Approval

This document has been prepared by the under-signed:
