Laboratory Control Sample/LCSD **(Accuracy and Precision)**	1 per 20 samples of similar matrix extracted at the same times. LCSs should be spiked at concentration near the mid point of the calibration curve.	Percent recoveries must be within laboratory control limits. For compounds without established laboratory control limits, 80-120% recovery will be used. For precision, RPD of 15% for sample concentrations near the mid-range of the calibration and RPD of 50% for sample concentrations near the low-range of the calibration. The lowest acceptable control limits for recovery will be 10%.	1. Reanalyze and examine results of other QC analyses. 2. If the percent recovery is above laboratory control limits and the affected compound is not detected in the associated samples, corrective action is not required; document in case narrative. 3. If percent recovery is below laboratory control limits or <10%, reanalyze LCS. If recoveries remain below limits and other QC criteria have been met, report both analyses and document in case narrative report. 4. If recoveries are below laboratory control limits and additional QC excursions are observed, locate and correct problem, recalibrate instrument and re-extract and/or re-analyze samples since last satisfactory LCS. 5. Document any observations and corrective action in the case narrative.
MS/MSD Analysis **(Accuracy and Precision)**	1 per 20 samples of similar matrix extracted at the same times. MS/MSDs must be spiked at concentration near the mid point of the calibration curve. Samples from the investigation must be used for MS/MSD analysis. If samples were not designated as MS/MSD samples, contact QAO upon receipt of samples at the laboratory.	Recovery and RPD within laboratory control limits. For aqueous – 80-120%R. For solids – 70-130%R For precision, RPD of 15% for sample concentrations near the mid-range of the calibration and RPD of 50% for sample concentrations near the low-range of the calibration. The lowest acceptable control limits for recovery will be 10%.	1. Reanalyze if <10%. 2. If reanalysis is still <10%, report both analyses and document in the case narrative. 3. If re-analysis is >10% and LCS criteria are met, document in case narrative; no additional corrective action required. 4. If LCS criteria are exceeded also, examine other QC data for source of problem; *i.e.,* surrogate recoveries for extraction efficiency and calibration data for instrument performance issues. 5. Re-extract or reanalyze samples and associated MS/MSD and LCSs as required. 6. Document any observations and corrective action in the case narrative.

Table 3-8. Perchlorate using USEPA Method 6850 quality control requirements and corrective actions

Audit Parameter (DQI)	Frequency	Control Limits	Laboratory Corrective Action
Internal Standards **(Accuracy)**	Where applicable: All samples and blanks (including MS/MSD)	Response -50% to +150% of average internal standard area from the ICAL. RT must be ± 30 sec. from associated calibration verification standard of that sequence.	1. Reanalyze. 2. If still outside of the limits, report both analyses. 3. Document any observations and corrective action in the case narrative.
Identification	Samples, blanks, and QC data.	The retention times of the mass-to-charge ratio for ions 83 and 85 must not vary by greater than 0.2 minutes. Compare relative abundance of mass-to-charge ratio ions 83 and 85; the 83/85 peak area counts must be within 30% of the average peak area count of the mid-range standard. Summary documentation of retention time and peak area count evaluation must be included in the data packages.	1. Investigate problem; reanalyze samples. 2. Document any observations and corrective action in the case narrative.
Quantitation	Samples, blanks, and QC data.	Internal standard method used. Verify concentration is within linear calibration range of standards. Every effort must be made to meet specified RL requirements.	1. If concentration is above linear calibration range, dilute sample and reanalyze. Dilution should result in concentration in the upper calibration range of the instrument. 2. Document any observations and corrective action in the case narrative.
Field Blank Analysis **(Sensitivity)**	Collected per QAPP requirements.	Less than RL.	1. Investigate problem; reanalyze to verify laboratory cross contamination is not a factor. 2. Document any observations and in the case narrative.

Table 3-8. Perchlorate using USEPA Method 6850 quality control requirements and corrective actions

Audit Parameter (DQI)	Frequency	Control Limits	Laboratory Corrective Action
Field Duplicate Analysis **(Precision)**	Collected per QAPP requirements.	Validation criteria: 30% RPD for waters, 50% RPD for solids. For sample results that are less than or equal to five times the RL, the criterion of plus or minus two times the RL will be applied to evaluate field duplicates.	No corrective action required of the laboratory since the laboratory will not know the identity of the field duplicate samples. If these criteria are not met, sample results will be evaluated on a case-by-case basis during the validation process.
Chromatography Presentation	For each standard, sample and QC sample analysis.	Copies of chromatograms provided in the data package must be large enough to view during validation. In the case that matrix interference is detected or manual integration is performed, enlarged copies of those manipulations will be included in the data package for review.	1. Provide requested information.
Sample Batching	The laboratory will batch project samples together along with QC samples specified from the project. Non-project information will not be included in the data packages.	Not applicable	Not applicable
Laboratory control limits	Generated with results for an analyte from a minimum of 20 sample analyses. The average of the sample results and the standard deviation are calculated. The internal warning limits are established at 2 times the standard deviation and the control limits are established at 3 times the standard deviation. The control limits are updated annually.	Not applicable	Not applicable
Percent solids	For solids samples, the percent solids will be determined and sample results will be corrected for percent solids.	Not applicable	Not applicable

Table 3-8. Perchlorate using USEPA Method 6850 quality control requirements and corrective actions

Audit Parameter (DQI)	Frequency	Control Limits	Laboratory Corrective Action
Dilutions	1. When target analyte concentration exceed upper limit of calibration curve. 2. When matrix interference demonstrated by lab and documented in the case narrative (highly viscous samples or a large number of non-target peaks on the chromatogram). . 3. Laboratory will note in the data deliverables which analytical runs were reported.	The reagent blank will meet the method blank criteria.	1. Reanalyze reagent blank until method blank criteria are met.
Deliverables as required	1. Full NJDEP deliverables must be provided to document each audit item for easy reference and inspection. 2. An example calculation will be provided for each analysis, for each type of matrix in the data package using samples from the project. 3. Any laboratory abbreviations or notations presented in the raw data or summary information will be explained or referenced in the case narrative. 4. Final spiking concentrations for calibrations, LCS, MS/MSD and internal standards will be presented in summary form. 5. Standard tracing information will be provided. 6. Cooler temperatures will be provided in the data packages. 7. Run logs with lab notations clearly identified will be provided in the data packages.	Not applicable	Provide missing or additional deliverables for validation purposes.

Table 3-8. Perchlorate using USEPA Method 6850 quality control requirements and corrective actions

Audit Parameter (DQI)	Frequency	Control Limits	Laboratory Corrective Action
Method and QAPP requirements	The laboratory will perform the method as presented in this QAPP and will adhere to the QAPP requirements presented herein. Otherwise the laboratory will specifically note any procedures that differ from the method or the QAPP in the data package case narrative.	Not applicable	Not applicable

Note

Data validation will be performed in accordance with QA/QC criteria established in these tables and the analytical methods that are currently used by the laboratory. Excursions from QA/QC criteria will be qualified based on guidance provided in this QAPP.

Communications with the QAO will be documented and included in the data packages.

Source: O'Brien & Gere

Table 3-9. Nitrocellulose using CT Laboratories SOPs VO 008 / WC 037 quality control requirements and corrective actions

Audit Parameter (DQI)	Frequency	Control Limits	Laboratory Corrective Action
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous and solid samples: cooler temperature ≤6°C. See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Holding times (Sensitivity)	Samples must be prepared and analyzed within holding time.	Aqueous - 28 days from collection to analysis Solid - 28 days from collection to analysis	1. If holding times are exceeded for initial or any re-analyses required due to QC excursions, notify the Project Manager immediately since re-sampling may be required. 2. Document any observations and corrective action in the case narrative.
Initial Calibration (IC) **(Accuracy)**	Prior to start up and when criteria are exceeded for continuing calibration. Quantitation of analyses will utilize the initial calibration results.	1. Minimally ten concentrations. One calibration standard must be at concentration less than or equal to the RL. 2. It is recommended that if results are reported below the RL, a separate standard at the MDL level analyzed after calibration is complete to check sensitivity. 3. A nonlinear first or second order calibration curve correlation coefficient of greater than 0.995.	1. Identify and correct problem. 2. Recalibrate instrument; samples should not be analyzed until initial calibration criteria are met. 3. Document any observations and corrective action in the case narrative.
Initial Calibration Verification (ICV) Continuing Calibration **Verification (CCV)** **(Accuracy)**	ICV is analyzed after each IC. CCVs must be analyzed every 10 samples and at the close of the sequence.	Recovery must be 90 to 110%	1. Reanalyze. 2. If criteria are still not met, identify and correct problem, recalibrate; reanalyze samples back to last compliant calibration standard. Samples must be bracketed by compliant calibration standards. 3. Document any observations and corrective action in the case narrative.

Table 3-9. Nitrocellulose using CT Laboratories SOPs VO 008 / WC 037 quality control requirements and corrective actions

Audit Parameter (DQI)	Frequency	Control Limits	Laboratory Corrective Action
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous and solid samples: cooler temperature ≤6°C. See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Initial Calibration Blank (ICB) **Continuing Calibration Blank (CCV)** **(Sensitivity)**	ICB is analyzed after each IC. CCBs must be analyzed every 10 samples and at the close of the sequence.	Less than RL	1. Reanalyze. 2. If limits are still exceeded, re-prepare and reanalyze method blank and associated samples. Samples must not be analyzed until method blank criteria are met. 3. Document any observations and corrective action in the case narrative.
Method Blank Analysis **(Sensitivity)**	Method Blank : 1 per 20 samples	Less than RL.	1. Reanalyze. 2. If limits are still exceeded, re-prepare and reanalyze method blank and associated samples. Samples must not be analyzed until method blank criteria are met. 3. Document any observations and corrective action in the case narrative.
Laboratory Control Sample **(Accuracy)**	1 per 20 samples of similar matrix extracted at the same times. LCSs must be spiked at concentrations near the low end of the calibration curve.	Percent recoveries must be within laboratory control limits. For compounds without established laboratory control limits, 70-130% recovery will be used. The lowest acceptable control limits for recovery will be 10%.	1. Reanalyze and examine results of other QC analyses. 2. If the percent recovery is above laboratory control limits and the affected compound is not detected in the associated samples, corrective action is not required; document in case narrative. 3. If percent recovery is below laboratory control limits or <10%, reanalyze LCS. If recoveries remain below limits and other QC criteria have been met, report both analyses and document in case narrative report. 4. If recoveries are below laboratory control limits and additional QC excursions are observed, locate and correct problem, recalibrate instrument and re-extract and/or re-analyze samples since last satisfactory LCS. 5. Document any observations and corrective action in the case narrative.

Table 3-9. Nitrocellulose using CT Laboratories SOPs VO 008/WC 037 quality control requirements and corrective actions

Audit Parameter (DQI)	Frequency	Control Limits	Laboratory Corrective Action
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous and solid samples: cooler temperature ≤6°C. See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
MS/MSD Analysis **(Accuracy and Precision)**	1 per 20 samples of similar matrix extracted at the same times. MS/MSDs must be spiked at concentrations near the low end of the calibration curve. Samples from the investigation must be used for MS/MSD analysis. If samples were not designated as MS/MSD samples, contact QAO upon receipt of samples at the laboratory.	Recovery and RPD within laboratory control limits. For compounds without established laboratory control limits, 70-130% recovery will be used. The lowest acceptable control limits for recovery will be 10%.	1. Reanalyze if <10%. 2. If reanalysis is still <10%, report both analyses and document in the case narrative. 3. If re-analysis is >10% and LCS criteria are met, document in case narrative; no additional corrective action required. 4. If LCS criteria are exceeded also, examine other QC data for source of problem; *i.e.*, surrogate recoveries for extraction efficiency and calibration data for instrument performance issues. 5. Re-extract or reanalyze samples and associated MS/MSD and LCSs as required. 6. Document any observations and corrective action in the case narrative.
Identification	Samples, blanks, and QC data.	Retention times must be within established retention time windows or must meet relative retention time criteria.	1. Investigate problem; reanalyze calibration standards to check for retention time shift. 2. Document any observations and corrective action in the case narrative.
Quantitation	Samples, blanks, and QC data.	External standard method used. Verify concentration is within linear calibration range of standards. Every effort must be made to meet specified RL requirements. Lab must state the technique used for quantitation of results for the samples.	1. If concentration is above linear calibration range, dilute sample and reanalyze. Dilution should result in concentration in the upper calibration range of the instrument. 2. Document any observations and corrective action in the case narrative.
Field Blank Analysis **(Sensitivity)**	Frequency as required by the Project.	Less than RL.	1. Investigate problem; reanalyze to verify laboratory cross contamination is not a factor. 2. Document any observations and in the case narrative.

Table 3-9. Nitrocellulose using CT Laboratories SOPs VO 008 / WC 037 quality control requirements and corrective actions

Audit Parameter (DQI)	Frequency	Control Limits	Laboratory Corrective Action
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous and solid samples: cooler temperature ≤6°C. See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Field Duplicate Analysis **(Precision)**	Frequency as required by the Project. Field duplicate will not be identified to the laboratory.	Validation criteria: 30% RPD for waters and 50% RPD for solids. For sample results that are less than or equal to five times the RL, the criterion of plus or minus two times the RL will be applied to evaluate field duplicates.	No corrective action required of the laboratory since the laboratory will not know the identity of the field duplicate samples. If these criteria are not met, sample results will be evaluated on a case-by-case basis during the validation process.

Audit Parameter (DQI)	Frequency	Laboratory Control Limits	Laboratory Corrective Action
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous and solid samples: cooler temperature ≤6°C, For aqueous samples, HCl to pH<2. See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Holding times (Sensitivity)	Samples must be analyzed within holding time.	Analyze 28 days from collection.	1. If holding times are exceeded for initial or any re-analyses required due to QC excursions, notify the QAO since re-sampling may be required.
Initial Calibration, Initial Calibration Verification (ICV) and Calibration Verification (CCV) **(Accuracy)**	At a minimum three to five standards (depending on method requirements) and a blank, prior to sample analysis and when calibration verification criteria are not met. One standard must be at the RL concentration. ICV accompanies each initial calibration. CCV is analyzed following calibration, after every 10 samples and at the end of the sequence to bracket sample analyses.	For initial calibration, correlation coefficient for first or second order curve must be ≥ 0.995. For ICV, CCV - 90% to 110% of expected value.	1. Reanalyze. 2. If criteria are still not met, identify and correct problem, recalibrate. 3. Document corrective action in the case narrative - samples cannot be analyzed until calibration control limit criteria have been met.
Calibration Blank (CB) **(Sensitivity)**	At beginning and end of run and at a rate of 10% during run.	Target analytes less than RL.	1. Identify and correct problem. 2. If criteria are still not met, recalibrate. 3. Document corrective action in the case narrative 4. Samples cannot be analyzed until blank control limit criteria have been met.

Table 3-10. TOC using USEPA Method 9060A quality control requirements and corrective actions.

Audit Parameter (DQI)	Frequency	Laboratory Control Limits	Laboratory Corrective Action
Preparation / Method Blank Analysis **(Sensitivity)**	1 per batch of samples analyzed in the sample batch.	Target analytes less than RL.	1. Reanalyze blank. 2. If limits are still exceeded, clean instrument and recalibrate analytical system and reanalyze affected samples if detected. 3. Document corrective action - samples cannot be analyzed until blank criteria are met.
Laboratory Control Sample Analysis **(Accuracy)**	Every 20 samples or each batch. Prepared independently from calibration standards.	Recovery within laboratory control limits or 80% to 120%. The lowest acceptable control limits for recovery will be 10%.	1. If recovery failures are above control limits and these target analytes are not detected in the associated samples, no corrective action is required. 2. If recovery failures are below the control limits, reanalyze LCS and examine results of other QC analyses. 3. If other QC criteria have not been met, stop analysis, locate and correct problem, recalibrate instrument and reanalyze samples since last satisfactory LCS. 4. Document corrective action in the case narrative.
Matrix Spike Analysis **(Accuracy)**	Collected per QAPP requirements. Samples from the investigation must be used for MS/MSD analysis. If samples were not designated as MS/MSD samples, contact QAO upon receipt of samples at the laboratory.	Recovery within laboratory control limits or 75-125%. Recovery does not apply if sample concentration > 4 X spike concentration. The lowest acceptable laboratory control limits for recovery will be 10%.	1. Investigate problem. 2. Document in the case narrative.

Table 3-10. TOC using USEPA Method 9060A quality control requirements and corrective actions.

Audit Parameter (DQI)	Frequency	Laboratory Control Limits	Laboratory Corrective Action
Laboratory Duplicate or Matrix Spike Duplicate Analysis **(Precision)**	Collected per QAPP requirements. Samples from the investigation must be used for Laboratory Duplicate and MSD analysis. If samples were not designated as QC samples, contact QA Officer upon receipt of samples at the laboratory.	Laboratory control limit or 20% for RPD shall be used for original and duplicate sample values greater than or equal to five times the RL. A control limit of the RL value shall be used if either the sample or duplicate value is less than five times the RL.	1. Investigate problem. 2. Document in the case narrative.
Field/Equipment Blank Analysis **(Sensitivity)**	Collected per QAPP requirements.	Target analytes less than RL.	1. Investigate problem. 2. Document in the case narrative.
Field Dup. Analysis **(Precision)**	Collected per QAPP requirements. Field duplicate will not be identified to the laboratory.	Validation criteria: 30% RPD for waters, 50% RPD for solids. For sample results that are less than or equal to five times the RL, the criterion of plus or minus two times the RL will be applied to evaluate field duplicates.	No corrective action required of the laboratory since the laboratory will not know the identity of the field duplicate samples. If these criteria are not met, sample results will be evaluated on a case-by-case basis.
Dilutions	Dilute and reanalyze samples with concentrations that are greater than the linear range of the instrument or method technique. The laboratory will note in the data package which analytical runs were used to report the sample results.	Not applicable	Not applicable. .
Sample Batching	The laboratory will batch project samples together along with QC samples specified from the project. Non-project information will not be included in the data packages.	Not applicable	Not applicable

Table 3-10. TOC using USEPA Method 9060A quality control requirements and corrective actions.

Audit Parameter (DQI)	Frequency	Laboratory Control Limits	Laboratory Corrective Action
Laboratory control limits	Generated with results for an analyte from a minimum of 20 sample analyses. The average of the sample results and the standard deviation are calculated. Note			
Data validation will be performed in accordance with QA/QC criteria established in these tables and the analytical methods. Excursions from QA/QC criteria will be qualified based on guidance provided in this QAPP.			
Communications with O'Brien & Gere will be documented and included in the data packages.			
Source: O'Brien & Gere			

Table 3-11A. Metals using USEPA Methods 6010D/6020B quality control requirements and corrective actions

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous and soil samples: cooler temperature ≤6°C. See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Holding times (Sensitivity)	Samples must be digested and analyzed within holding time.	Metals: 180 days from collection to analysis.	If holding times are exceeded for initial or any re-analyses required due to QC excursions. Notify QAO since re-sampling may be required. Document corrective action in the case narrative.
ICP/MS tuning, mass calibration and resolution checks **(Accuracy)**	Analyze tune solution at least 4 times after the instrument has equilibrated prior to sample analysis. Evaluate mass calibration and resolution checks in the mass regions of interest. Solution contains elements representing all the of mass regions of interest (such as Li, Co, In, Tl) to verify resolution and mass calibration within criteria.	1. RSD must be <15% for analytes in the tune solution, with 200 continuous scans. 2. If mass calibration is >0.1amu from the true value, mass calibration must be adjusted to correct values. 3. Resolution must be less than 0.9amu of full width at 10% of peak height. 4. Documentation of mass calibration and resolution evaluations may be requested.	1. Identify and correct problem, and retune instrument - samples cannot be analyzed until tune criteria is met.
Initial Calibration Verification and Continuous Calibration Verification **(ICV, CCV)** **(Accuracy)**	ICP calibration curve is analyzed on a daily basis that employs a minimum of a calibration blank and three standards for each target analyte. After calibration, Initial calibration verification (ICV) is performed. The ICV is from a source independent of the calibration standards. A continuing calibration verification (CCV) is analyzed at the beginning of the run, at 10%. Also verify at the end of each run.	ICV, CCV - 90% to 110% of expected value for ICP, AA, colorimeter, and spectrophotometer. ICV for Mercury – 90% to 110% of expected true value. CCV for Mercury - 80% to 120% of expected true value. Correlation coefficient for first or second order curve must be ≥ 0.995.	Reanalyze. If criteria are still not met, identify and correct problem, recalibrate. Document corrective action in the case narrative - samples should not be analyzed until calibration control limit criteria have been met.

Table 3-11A. Metals using USEPA Methods 6010D/6020B quality control requirements and corrective actions

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
ICP/MS **Initial and continuing calibration verification** **(ICV, CCV)** **(Accuracy)**	ICP/MS calibration curve is analyzed on a daily basis that employs a minimum of a calibration blank and three standards for each target analyte. Calibration standard solutions must contain appropriate internal standard for each target element. Calibration solution must be initially verified using a QC standard and monitored weekly for stability. The initial calibration verification (ICV) must be prepared in the same matrix as the calibration standards but as a independent standard near the midpoint of the linear range at a concentration other than the calibration standards. . Verify calibration with ICV, ICB immediately after calibration. Verify with CCV, CCB at frequency of every 10 samples and at the end of the sequence. For ICP/MS, prior to preparing standards, each stock solution must be analyzed separately to determine any interferences.	ICV, CCV must be 90% to 110% of expected value for ICP/MS, and cyanide. If the ICP/MS is resloped or recalibrated after the ICV is analyzed, a new CCV, CCB must be analyzed prior to sample analysis. Provide documentation of calibration standard monitoring and evaluation.	1. Reanalyze. 2. If criteria are still not met, terminate analysis, identify and correct problem, recalibrate, and contact QAO. 3. Document corrective action in case narrative - samples cannot be analyzed until calibration control limit criteria have been met.
Lower Limit of Quantitation Check (LLQC) **(Accuracy)**	For ICP, LLQC is a standard at the RL concentration analyzed quarterly for all elements at the RL level.	The percent recovery of the LLQC must meet the laboratory established control limits.	The LLQC shall be re-analyzed immediately for those analytes; if the results of the re-analysis for those analytes fall within the control limits, no further corrective action is required. If the results of the re-analysis for those analytes do not fall within the control limits, the analysis shall be terminated, the problem corrected, the instrument recalibrated, the LLQC analyzed, and the samples associated with the LLQC re-analyzed. Document any observation or corrective action in the case narrative.

Table 3-11A. Metals using USEPA Methods 6010D/6020B quality control requirements and corrective actions

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Internal Standard **(Accuracy)**	Monitored for all samples, blanks, standards, and QC samples analyzed.	Internal standard counts should be within 30% of Internal standard counts of the calibration standard for all samples and standards.	1. If internal standard area is not within 30%, review the internal areas of the closest calibration blanks for compliance. If the calibration blanks meet criteria; dilute the sample five fold and reanalyze. 2. If the internal standard area of the calibration blank is also outside of 30%, stop sample analysis and recalibrate.
Internal Standard for ICP/MS **(Accuracy)**	Appropriate internal standard as listed in Method 6020 is required for each analyte. The internal standard should be no more than 50 amu from the target element. Recommended internal standards include 6Li, 45 Sc, 89Y, 103 Rh, 115In, 159Tb, 169Ho, 209Bi.	Intensity of all internal standards must be monitored for every analysis. The intensity of any internal standard must be >70% or <130% of the intensity of the internal standard in the initial calibration standard or blank. Document internal standard intensity and the evaluation for each analysis performed and include in the data package.	If sample analysis fails, dilute the sample fivefold (1+4), adjust internal standard and reanalyze. Repeat until internal standard intensify meets criteria. If the CCB or CCV intensity fails, terminate analysis, identify and correct problem, recalibrate, verify calibration and reanalyze samples, document in the case narrative, and contact QAO.
Low level Standard Analysis (Accuracy)	For ICP, Low Level Standard is the RL concentration at the beginning of each run for all elements at the RL level	The percent recovery of the Low Level Standard must meet the control limits of 80-120%.	The CRDL shall be re-analyzed immediately for those analytes; if the results of the re-analysis for those analytes fall within the control limits, no further corrective action is required. If the results of the re-analysis for those analytes do not fall within the control limits, the analysis shall be terminated, the problem corrected, the instrument recalibrated, the CRDL analyzed, and the samples associated with the CRDL re-analyzed. Document corrective action in case narrative.
Initial and Continuing Calibration Blank (ICB/CCB) **(Metals, mercury, cyanide)**	After ICV, CCV, at beginning and end of run and at a rate of 10th sample.	The absolute value of the ICB and CCB must not exceed the RL.	Identify and correct problem. If criteria are still not met, recalibrate and reanalyze affected samples. Document corrective action in the case narrative - samples should not be analyzed until blank control limit criteria have been met.

Table 3-11A. Metals using USEPA Methods 6010D/6020B quality control requirements and corrective actions

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Preparation Blank Analysis **(Sensitivity)**	1 per batch of samples digested, or 1 in 20, whichever is greater. PB shall be carried through the complete procedure and contain the same acid concentration in the final solution as the sample solution used for analysis.	The absolute value of the method blank must not exceed the RL.	Reanalyze blank. If limits are still exceeded, clean instrument and recalibrate analytical system and re-preparation and reanalyze affected samples if detected. Document corrective action in the case narrative - samples cannot be analyzed until blank criteria are met.
Field Blank Analysis **(Sensitivity)**	Collected one per 10 samples or once per sampling event.	Less than RL	Investigate problem. Document in the case narrative.
Laboratory Control Sample (LCS) Analysis **(Accuracy)**	Every 20 samples or each digestion batch. Prepared independently from calibration standards. LCS must contain all target analytes.	Recovery within laboratory control limits. The lowest acceptable control limits for recovery will be 10%.	Reanalyze LCS and examine results of other QC analyses. If recovery is still outside limits, and other QC criteria are met, report both runs. If other QC criteria have not been met, stop analysis, locate and correct problem, recalibrate instrument and reanalyze samples since last satisfactory LCS. Document corrective action in the case narrative.
Serial Dilution Analysis for ICP (Accuracy)	Required once per analytical batch when analyte concentration is >50 times the instrument IDL or MDL. Samples from the investigation must be used for Serial dilution analysis.	An analysis of a 1:5 dilution of the sample should provide a result within 20%Dof the original determination (for concentrations 25x the MDL.	Report results. Document corrective action in the case narrative.
Serial Dilution Analysis for ICP/MS **(Accuracy)**	Required when analyte concentration is >100 times the reagent blank and is within the linear range of the ICP/MS. Performed for every 20 samples for each matrix or per batch.	An analysis of a 1:5 dilution of the sample should provide a result within 20%D of the original determination (for concentrations 25x the MDL).	Qualify data. Document corrective action in the case narrative.

Table 3-11A. Metals using USEPA Methods 6010D/6020B quality control requirements and corrective actions

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Spectral Interference Check (SIC) Solution Analysis for ICP **(Accuracy)**	Beginning of each analytical for ICP. Solution A consists of the interferents, and Solution AB consists of the analytes mixed with the interferents.	Results for the unspiked analytes must be less than 2xRL. Percent recoveries for the spiked analytes must be within 80-120%R.	Reanalyze. If limits are still exceeded, adjust instrument. Restart analytical run and reanalyze samples analyzed since last satisfactory SIC solution. Document corrective action in the case narrative.
Spectral Interference Check (SIC) Solultion Analysis for ICP/MS **(Accuracy)**	Beginning of each analytical run or once during every 12 hours, whichever is more frequent for ICP/MS. For measurement of elemental, molecular-ion isobaric interference corrections. SIC solutioncontains known concentration of interfering elements that will demonstrate the magnitude of the molecular-ion isobaric interferences to verify that the interferences are corrected by the data system within the control limits.	Percent recovery of spiked elements must be within current laboratory control limits. Results for the unspiked analytes must be <2xRL.	Reanalyze. If limits are still exceeded, adjust interference corrections for instrument, contact QAO, samples cannot be analyzed until ICSA/ICSAB control limit criteria have been met. Restart analytical run and reanalyze samples analyzed since last satisfactory ICS. Document corrective action in the case narrative.
Matrix Spike/ **Matrix Spike Dup. (MS/MSD) Analysis** **(Accuracy/Precision)**	Collected per QAPP requirements. Samples from the investigation must be used for MS/MSD analysis. Spike must contain complete list of target analytes.	Recovery within laboratory control limits or 75-125%, or in-house laboratory limits. Recovery does not apply if sample concentration > 4 X spike concentration. Spike must contain all analytes. The lowest acceptable laboratory control limits for recovery will be 10%.	Analyze post-digestion/post-distillation spike. Document corrective action in the case narrative.
Post-Digestion Spike (Recommended for Metals) **(Accuracy)**	Spike must contain all target elements. Performed when MS/MSD fails.	Recovery within 75-125% of true value.	Dilute sample and reanalyze. If recovery is outside limits, document in the case narrative. Standard additions may be used to compensate for matrix effects.

Table 3-11A. Metals using USEPA Methods 6010D/6020B quality control requirements and corrective actions

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Internal standard **(Metals)** **(Accuracy)**	May be used for each sample instead of post-digestion spike.	Internal Standard counts must be within 30% of Internal Standard counts of ICB	Reanalyze.
Laboratory Duplicate or Matrix Spike Duplicate Analysis **(Precision)**	Collected one per 20 samples or one per matrix (for less than 20 samples) Samples from the investigation must be used for Laboratory Duplicate and MSD analysis	Laboratory control limit or 20% for RPD shall be used for original and duplicate sample values greater than or equal to five times the RL. A control limit of the RL value shall be used if either the sample or duplicate value is less than five times the CRRL.	Investigate problem and reanalyze. Document corrective action in the case narrative.
Field Duplicate Analysis **(Precision)**	Collected 1 per matrix; every 20 samples of similar matrix. The field duplicate identification will not be provided to the laboratory.	Validation criteria: 30% RPD for waters and 50% RPD for solids. For sample results that are less than or equal to five times the RL, the criterion of plus or minus two times the RL will be applied to evaluate field duplicates.	No corrective action required of the laboratory since the laboratory will not know the identity of the field duplicate samples. If these criteria are not met, sample results will be evaluated on a case-by-case basis.
Percent solids	For solid samples, the percent solids will be determined and sample results will be corrected for percent solids.	Not applicable	Not applicable
Laboratory control limits	Generated with results for an analyte from a minimum of 20 sample analyses. The average of the sample results and the standard deviation are calculated. The internal warning limits are established at 2 times the standard deviation and the control limits are established at 3 times the standard deviation. The control limits are updated annually.	Not applicable	Not applicable
IDL Determination for ICP	Recommended within 30 days of the start of analysis and semiannually.	Not applicable	Not applicable

Table 3-11A. Metals using USEPA Methods 6010D/6020B quality control requirements and corrective actions

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
System Operation for ICP/MS	Use an average of 3 integrations for both the calibration and sample analysis. All masses which could affect data quality will be monitored to determine the potential effect from the matrix. Isotopes listed in the method should be used.	Not applicable	Not applicable
Interference monitoring for ICP/MS	The analyst is required to monitor potential sources of interferences by measuring the elements of interest or a molecular species that may indicate the presence of an interferent and by taking appropriate action to ensure data of known quality. Interferences must be corrected by using correction equations based on observed isotopic signals and by monitoring the intensity of the internal standards. Samples exhibiting isobaric elemental interferences (isotopes of different elements with similar mass to charge ratio or very high ion currents at adjacent masses) require resolution improvement, matrix separation, or alternate isotopes. The rinse period between samples must be long enough to eliminate significant memory interferences. 5. Extensive QC for interference corrections must be performed.	Not applicable	Not applicable

Table 3-11A. Metals using USEPA Methods 6010D/6020B quality control requirements and corrective actions

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Analyte quantitation	Concentrations for ICP/MS analysis are reported based on dry weight of the sample. Calculations for the ICP/MS should include appropriate interference corrections, internal standard normalization, and summation of signals at 206, 207, and 208 mass to charge for lead. All QC criteria must be met when applying correction equations. If interference is detected, elements impacted are flagged to indicate percentage interference correction applied to the data or an uncorrected interference because of the equation used for quantitation.	Not applicable	Not applicable
Dilutions for ICP/MS	Analyze samples at a 1:5 dilution. Dilute and reanalyze samples with concentrations that are still greater than the linear range of the instrument. The laboratory will note in the data package which analytical runs were used to report the sample results.	Not applicable	Not applicable
MDL Determination	Before any field samples are analyzed, the MDLs shall be determined for non-prepared analyses, each digestion procedure and instrument used, prior to the start of analyses, and annually thereafter.	Not applicable	Not Applicable
Linear Range Analysis for ICP	Every 6 months.	Not applicable	Not applicable

Table 3-11A. Metals using USEPA Methods 6010D/6020B quality control requirements and corrective actions

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Interelement Correction For ICP	Within 6 months of the start of analysis and annually.	Not applicable	Not applicable
Sample Batching	The laboratory will batch project samples together along with QC samples specified from the project. Non-project information will not be included in the data packages.	Not applicable	Not applicable
Dilutions	When target analyte concentration exceed upper limit of calibration curve. When matrix interference demonstrated by lab and documented in the case narrative. Laboratory will note in the data deliverables which analytical runs were reported.	Not applicable	Not applicable
Deliverables as required	Full NJDEP deliverables must be provided to document each audit item for easy reference and inspection. An example calculation may be requeted for each analysis, for each type of matrix in the data package using samples from the project. Any laboratory abbreviations or notations presented in the raw data or summary information will be explained or referenced in the case narrative. Final spiking concentrations will be presented in summary form. Standard tracing information will be provided. Cooler temperatures will be provided in the data packages. Run logs will be provided in the data packages.	Not applicable	Provide missing or additional deliverables for validation purposes.

Table 3-11A. Metals using USEPA Methods 6010D/6020B quality control requirements and corrective actions

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Method and QAPP Requirements	The laboratory will perform the method as presented in this QAPP and will adhere to the QAPP requirements presented herein. Otherwise the laboratory will specifically note any procedures that differ from the method or the QAPP in the data package case narrative.	Not applicable	Not applicable

Notes:

Data validation will be performed in accordance with QA/QC criteria established in these tables and the analytical methods. Excursions from QA/QC criteria will be qualified based on guidance provided in this QAPP.

Communications with O'Brien & Gere will be documented and included in the data packages.

Table 3-11B. Mercury using USEPA Methods 7470A/7471B, total cyanide using USEPA Method 9012B and pH quality control requirements and corrective action

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous and soil samples: cooler temperature ≤6°C. See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Holding times (Sensitivity)	Samples must be digested and analyzed within holding time.	Mercury: 28 days from collection to analysis. Total Cyanide: 14 days from collection to analysis. pH: Method hold time is 15 minutes from collection to analysis. Mercury prepared by SPLP - 28 days from collection to extract generation, 28 days from extraction to analysis.	If holding times are exceeded for initial or any re-analyses required due to QC excursions. Notify QAO since re-sampling may be required. Document corrective action in the case narrative.
Initial Calibration Verification and Continuous Calibration Verification **(ICV, CCV)** **(Accuracy)**	Five point calibration for Hg including a blank. Five point calibration for remaining methods, with one standard at the RL level. Calibrate each time instrument is set up. After calibration, Initial calibration verification (ICV) is performed. The ICV is from a source independent of the calibration standards. A continuing calibration verification (CCV) is analyzed at the beginning of the run, at 10% or every 2 hours. Also verify at the end of each run.	ICV, CCV - 90% to 110% of expected value for ICP, AA, colorimeter, and spectrophotometer. ICV for Mercury – 90% to 110% of expected true value. CCV for Mercury - 80% to 120% of expected true value. Correlation coefficient for first or second order curve must be ≥ 0.995. For cyanide the ICV must meet 85 to 115% recovery. For cyanide the CCV must meet 90-110% recovery For pH repeat adjustments on successive portions of the two buffer solutions until readings are within 0.05 pH units of the buffer solution value..	Reanlyze. If criteria are still not met, identify and correct problem, recalibrate. Document corrective action in the case narrative - samples should not be analyzed until calibration control limit criteria have been met.

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Lower Limit of Quantitation Check (LLQC) **(Accuracy)**	For AA, and cyanide, LLQC is the RL concentration at the beginning of each run for all elements at the RL level	The percent recovery of the LLQC must meet the control limits of 70-130%.	The LLQC shall be re-analyzed immediately for those analytes; if the results of the re-analysis for those analytes fall within the control limits, no further corrective action is required. If the results of the re-analysis for those analytes do not fall within the control limits, the analysis shall be terminated, the problem corrected, the instrument recalibrated, the LLQC analyzed, and the samples associated with the LLQC re-analyzed. Document corrective action in case narrative.
Initial and Continuing Calibration Blank (ICB/CCB) **(Metals, mercury, cyanide)**	After ICV, CCV, at beginning and end of run and at a rate of 10th sample or every 2 hours during run.	The absolute value of the ICB and CCB must not exceed the RL.	Identify and correct problem. If criteria are still not met, recalibrate and reanalyze affected samples. Document corrective action in the case narrative - samples should not be analyzed until blank control limit criteria have been met.
Preparation Blank Analysis **(Sensitivity)**	1 per batch of samples digested, or 1 in 20, whichever is greater. PB shall be carried through the complete procedure and contain the same acid concentration in the final solution as the sample solution used for analysis.	The absolute value of the method blank must not exceed the RL.	Reanalyze blank. If limits are still exceeded, clean instrument and recalibrate analytical system and re-preparation and reanalyze affected samples if detected. Document corrective action in the case narrative - samples cannot be analyzed until blank criteria are met.
Field Blank Analysis **(Sensitivity)**	Collected one per 10 samples or once per sampling event.	Less than RL	Investigate problem. Document in the case narrative.
Rinse Blank **(Sensitivity)**	Rinse blank must be analyzed following every sample and standard to flush the instrument.	Not applicable.	Not applicable.

Table 3-12. Total Phenols using USEPA Method 9066 and nitrate using USEPA Method 353.2/300.0 quality control requirements and corrective actions.

Audit Parameter (DQI) where applicable	Frequency	Control Limits	Corrective Action
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous samples: cooler temperature ≤6°C, preserve with H_2SO_4 to pH≤2. For solid samples: cooler temperature ≤6°C. See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Holding times (Sensitivity)	Samples must be prepared and analyzed within holding time.	Phenols: Analyze 28 days from collection. Nitrate: Analyze 48 hrs from collection. 28 days from collection to analysis if preserved	1. If holding times are exceeded for initial or any re-analyses required due to QC excursions, notify the Quality Assurance Officer (QAO) since re-sampling may be required.
Initial Calibration and Calibration Verification **(ICV, CCV)** **(Accuracy)**	At a minimum three to five standards (depending on method requirements) and a blank, prior to sample analysis and when calibration verification criteria are not met.. One standard must be at the QL concentration. ICV accompanies each initial calibration. CCV is analyzed following calibration, after every 10 samples and at the end of the sequence to bracket sample analyses.	Linear calibration with correlation coefficient greater than 0.995. For ICV, CCV - 90% to 110% of expected value.	1. Reanalyze. 2. If criteria are still not met, identify and correct problem, recalibrate. 3. Document corrective action in the case narrative - samples cannot be analyzed until calibration criteria have been met.
Calibration Blank **(Sensitivity)**	At beginning and end of run and at a rate of 10% during analysis sequence.	The absolute value of the target analyte must be less than QL.	1. Identify and correct problem. 2. If criteria are still not met, recalibrate. 3. Document corrective action in the case narrative 4. Samples cannot be analyzed until blank control limit criteria have been met.

Table 3-12. Total Phenols using USEPA Method 9066 and nitrate using USEPA Method 353.2/300.0 quality control requirements and corrective actions.

Audit Parameter (DQI) where applicable	Frequency	Control Limits	Corrective Action
Preparation/Method Blank Analysis **(Sensitivity)**	1 for each batch of samples prepared in the sample batch.	Target analytes less than QL.	1. Reanalyze blank. 2. If limits are still exceeded, clean instrument and recalibrate analytical system and re-preparation and reanalyze affected samples if detected. 3. Document corrective action - samples cannot be analyzed until blank criteria are met.
Laboratory Control Sample Analysis **(Accuracy)**	Every 20 samples or each preparation batch. Prepared independently from calibration standards.	Recovery within laboratory control limits or 80% to 120%. The lowest acceptable control limits for recovery will be 10%.	1. If recovery failures are above control limits and these target analytes are not detected in the associated samples, no corrective action is required. 2. If recovery failures are below the control limits, reanalyze LCS and examine results of other QC analyses. 3. If other QC criteria have not been met, stop analysis, locate and correct problem, recalibrate instrument and reanalyze samples since last satisfactory LCS. 4. Document corrective action in the case narrative.
Matrix Spike Analysis **(Accuracy)**	Collected per QAPP requirements. Samples from the investigation must be used for MS/MSD analysis. If samples were not designated as MS/MSD samples, contact QAO upon receipt of samples at the laboratory.	Recovery within laboratory control limits or 75-125%. Recovery does not apply if sample concentration > 4 X spike concentration. Spike must contain all analytes. The lowest acceptable laboratory control limits for recovery will be 10%.	1.Re-aAnalyze 2. Document corrective action in the case narrative.

Table 3-13. Methyl Mercury using USEPA Modified Method 1630 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous samples: cooler temperature ≤6°C. For solid samples: cooler temperature ≤6°C. See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Method Summary – Methyl Mercury in aqueous or solid media, USEPA Modified Method 1630, Based on Eurofins Frontier Global Sciences SOP **EFASF-T-AFS-SOP2808**	Mono Methyl Mercury measured by Cold Vapor- Gas Chromatography- Atomic Fluorescence Spectrometry (CV-GC-AFS). The sample is pH adjusted and ethylated in a closed vessel. The volatile Elemental Mercury [Hg (0)] and ethyl derivatives and labile Hg (II) (methyl ethyl and diethyl mercury) are purged onto a trap. The trap is dried then placed into a train; analytes are thermally desorbed into an inert gas, separated by a GC column, passed through a pyrolytic column to convert to detectable Elemental Mercury, then to the CVAFS for detection. Aqueous samples are collected directly into a rigorously cleaned, pretested, polyethylene terephthalate glycol-modified (PETG) bottle using sample handling techniques designed for collection of mercury at trace levels, with minimum headspace and acid-preserved. Solid samples are collected into clean wide mouth glass or high density polyethylene or glass jars with Teflon-lined caps and are preserved by freezing to -11 °C upon receipt. Maximum holding time is 180 days from collection to analysis.		
Holding times (Sensitivity)	Samples must be digested and analyzed within holding time.	Aqueous samples are collected directly into a rigorously cleaned, pretested, polyethylene terephthalate glycol-modified (PETG) bottle using sample handling techniques designed for collection of mercury at trace levels. Aqueous samples are acid preserved upon receipt at the laboratory. For preserved samples, the time to analysis is 6 months if kept in the dark and cool. Solid samples are collected into wide mouth glass or high density polyethylene jars and are preserved by freezing upon receipt. Solid samples must be analyzed 180 days from collection.	1. If holding times are exceeded for initial or any reanalysis required due to QC excursions, notify the QAO since re-sampling may be required. 2. Document any observation or corrective action in the case narrative.

Table 3-13. Methyl Mercury using USEPA Modified Method 1630 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Initial Calibration **(Accuracy)**	Initial calibration consists of at least five calibration standards (0.05 to 4 ng/L) and one instrument calibration blank (IBL) following ICV. The lowest calibration point must be at the quantitation limit (QL) or lower.	Subtract the peak area of the IBL for each standard and sample. Calculate the calibration factor for Hg in each of the five standards. Criteria for the calibration: 1. RSD ≤ 15%. 2. Recovery for the lowest standard (0.05 ng/L) 65-135%R.	1. If RSD ≤ 15%, calculate sample results using the average response factor. 2. If RSD > 15% or if the recovery of the lowest standard is not in the range of 65-135%, recalibrate the analytical system and repeat the calibration check. 3. Document any observation or corrective action in the case narrative - samples cannot be analyzed until calibration control limit criteria have been met.
Initial Calibration Verification and Calibration Verification **(ICV/CCV)** **(Accuracy)**	Analyze the ICV after initial calibration and CCV solution (0.5 ng/L) after every 10 analyses and at the end of the sequence.	ICV/CCV Criteria: ICV - Recovery must be within 67-133%. CCV - Recovery must be within 67-133%.	1. Reanalyze. 2. If criteria are still not met, identify and correct problem, recalibrate and re-analyze samples. 3. Document any observation or corrective action in the case narrative – samples cannot be reported until ICV/CCV criteria have been met at the beginning and end of each batch.
Instrument Calibration Blank (ICB) **(Sensitivity)**	Instrument calibration blanks are analyzed to demonstrate freedom from system contamination. The ICB must be analyzed per analytical batch, after the ICV. The blank for an analytical batch, if within acceptance criteria, is subtracted from all raw data for that batch prior to the calculation of results.	1. If the blank is greater than the RL the system is out of control.	1. The problem must be investigated and remedied, and the associated samples must be reanalyzed. 2. Document any observation or corrective action in the case narrative – samples cannot be analyzed until blank criteria have been met.

Table 3-13. Methyl Mercury using USEPA Modified Method 1630 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Continuing Calibration Blank (CCB) **(Sensitivity)**	CCBs are analyzed to demonstrate freedom from system contamination. The CCB must be analyzed every 10 samples.	1. If the blank is greater than the RL the system is out of control.	1. The problem must be investigated and remedied, and the associated samples must be reanalyzed. 2. Document any observation or corrective action in the case narrative – samples cannot be analyzed until blank criteria have been met.
Method Blank **(Sensitivity)**	Method blanks are used to demonstrate that the analytical system is free from contamination that could otherwise compromise sample results and are prepared and analyzed using sample containers, labware, reagents, and analytical procedures identical to those used to prepare and analyze the samples. A minimum of three method blanks per analytical batch are required.	1. The mean for 3 method blanks must be less than 0.045 ng/L Hg with standard deviation of <0.015 ng/L or the system is out of control. 2. Mercury in the analytical system must be reduced until a method blank is free from contamination at the 0.045 ng/L level. Samples associated with a contaminated method blank must be reanalyzed. 3. The average method blank for an analytical batch, if within acceptance criteria, is subtracted from all raw data for that batch prior to the calculation of results.	1. The problem must be investigated and remedied and samples re-analyzed. 2. Document any observation or corrective action in the case narrative – samples cannot be analyzed until method blank control limit criteria have been met.
Field Blank Analysis **(Sensitivity)**	Field collected - Field blank(s) are samples collected as per the QAPP, from the same site at the same time, to a maximum of 10 samples. Analyze the blank immediately before analyzing the samples in the batch.	1. If Hg is found in the field blank at a concentration equal to or greater than the RL, results for associated samples may be the result of contamination and may not be reported.	If contamination of the field blank and associated samples is known or suspected, the laboratory should communicate this to the sampling team so that the source of contamination can be identified.

Table 3-13. Methyl Mercury using USEPA Modified Method 1630 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Equipment Blank Analysis **(Sensitivity)**	Before any sampling equipment is used at a given site equipment blanks are generated on all sampling equipment that will be used to demonstrate that the sampling equipment is free from contamination. Equipment blanks are generated i by processing reagent water through the sampling devices using the same procedures that are used in the field. Therefore, the "clean hands/dirty hands" technique used during field sampling should be followed when preparing equipment blanks at the laboratory or cleaning facility for low level mercury measurements.	1. If Hg is found in the equipment blank at a concentration equal to or greater than the RL, results for associated samples may be the result of contamination and may not be reported.	If contamination of the equipment blank and associated samples is known or suspected, the laboratory should communicate this to the sampling team so that the source of contamination can be identified.
Quality Control Sample (QCS) / Laboratory Control Sample Analysis / LCSD **(Accuracy)**	Prepared independently from calibration standards at mid-point of the concentration range or at the CCV concentration and analyzed at the mid-point of the analytical batch.	Recovery must be within 70-130%. RPD must be <25RPD.	1. Reanalyze LCS and examine results of other QC analyses. 2. If other QC criteria have not been met, stop analysis, locate and correct problem, recalibrate and reanalyze samples since last satisfactory LCS. 3. Document any observation or corrective action in the case narrative.
Matrix Spike Analysis / Matrix Spike Duplicate **(Accuracy and Precision)**	One for each batch of 10 samples of similar matrix.	1. Recovery must be within 65-130%. 2. RPD less than or equal to 35.	1. Reanalyze and examine results of other QC analyses. 2. Document any observation or corrective action in the case narrative.

Table 3-13. Methyl Mercury using USEPA Modified Method 1630 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Field Duplicate Analysis (Precision)	Collected per the QAPP	Validation criteria: 30% RPD for waters, 50% RPD for solids. For sample results that are less than or equal to five times the RL, the criterion of plus or minus two times the RL will be applied to evaluate field duplicate.	No corrective action required of the laboratory since the laboratory will not know the identity of the field duplicate samples. If these criteria are not met, sample results will be evaluated on a case-by-case basis.
Target Analyte Identification	Not applicable	Species are eluted according to molecular weights, with the following peaks being typical for most analysis. A peak corresponding to elemental mercury, Hg(0), appears first. The second peak corresponds to methyl ethyl mercury. This is the peak of interest, the ethylation product of methyl mercury. The third peak corresponds to diethyl mercury, resulting from the ethylation of Hg(II)—inorganic mercury in the reagents and sample. This is not quantitative for Hg(II), however, as most Hg(II) is excluded by the distillation procedure.	Not applicable
Laboratory control limits	Generated with results for an analyte from a minimum of 5-10 sample analyses. The average of the sample results and the standard deviation are calculated. The internal warning limits are established at 2 times the standard deviation and the control limits are established at 3 times the standard deviation. The control limits are updated annually.	Not applicable	Not applicable

Table 3-13. Methyl Mercury using USEPA Modified Method 1630 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
MDL Determination	Each time this Method is modified, the laboratory is required to repeat the procedure to demonstrate that an MDL (40 CFR Part 136, Appendix B) less than or equal to one-third the regulatory compliance level or less than or equal to the MDL of this Method, whichever is greater, can be achieved.	Not applicable	Not applicable
Preparation Batch / Analytical Run	An analytical run is a set of samples prepared with the same batch of analytical reagents, and analyzed during the same 12-hour shift. Multiple preparation batches could exist on a single analytical run. A preparation batch may be from 1 to 20 samples prepared with the same batch of reagents at the same time. Each batch must be accompanied by at least three blanks, and a LCS/LCSD. In addition, there must be one MS and one MSD sample for every 10 samples (a frequency of 10%).	Not applicable	Not applicable
Sample Batching	The laboratory will batch project samples together along with QC samples specified from the project. Non-project information will not be included in the data packages.	Not applicable	Not applicable

Table 3-13. Methyl Mercury using USEPA Modified Method 1630 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Dilutions	When target analyte concentration exceed upper limit of calibration curve or when non-target analytes exceed the high limit of the system. When matrix interference demonstrated by lab and documented in the case narrative. Laboratory will note in the data deliverables which analytical runs were reported.	Not applicable	Not applicable
Deliverables as required	Full NJDEP deliverables must be provided to document each audit item for easy reference and inspection. An example calculation will be provided for each analysis, for each type of matrix in the data package using samples from the project. Any laboratory abbreviations or notations presented in the raw data or summary information will be explained or referenced in the case narrative. Final spiking concentrations will be presented in summary form. Standard tracing information will be provided. Cooler temperatures will be provided in the data packages. Run logs will be provided in the data packages.	Not applicable	Provide missing or additional deliverables for validation purposes.

Table 3-13. Methyl Mercury using USEPA Modified Method 1630 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Method and QAPP requirements	The laboratory will perform the method as presented in this QAPP and will adhere to the QAPP requirements presented herein. Otherwise the laboratory will specifically note any procedures that differ from the method or the QAPP in the data package case narrative.	Not applicable	Not applicable

Note

Data validation will be performed in accordance with QA/QC criteria established in these tables and the analytical methods that are currently used by the laboratory. Excursions from QA/QC criteria will be qualified based on guidance provided in this QAPP.

Communications with the QAO will be documented and included in the data packages.

Table 3-13A. Dimethyl Mercury using USEPA Modified Method 1630 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous samples: cooler temperature ≤6°C. For solid samples: cooler temperature ≤6°C. See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Method Summary – Dimethyl Mercury in aqueous or solid media, USEPA Modified Method 1630, Based on Eurofins Frontier Global Sciences EFAFS-T-AFS-SOP2816	Dimethyl Mercury ($(CH_3)_2Hg$) in aqueous and solids measured by Cold Vapor- Gas Chromatography- Atomic Fluorescence Spectrometry (CV-GC-AFS). Samples are stored unpreserved in a cool, dark location until analysis. Solids are digested to release bound methyl mercury. In the aqueous sample/extract, volatile dimethyl mercury is separated from the matrix by purging onto a trap. The trap is thermally desorbed into an inert gas, separated by a GC column, then to the CVAFS for detection.		
Sample Collection and Holding times (Sensitivity)	Samples must be digested and analyzed within holding time.	Unfiltered aqueous samples are collected using rigorous ultra-clean protocols into a rigorously cleaned, glass or quartz bottle with Teflon™ lined caps. Samples are unpreserved in a cool, dark location for less than 48 hours until analysis. If samples cannot be analyzed within 48 hours of sampling the sample should be purged onto a carbo trap to extend the holding time to 28 days. Solid samples are collected into 60 -125 milliliter glass jars with Teflon™ lined caps to 80-90% full, placed on ice and overnight shipped to the laboratory where they are preserved by freezing to -11 °C upon receipt. Analysis holding time is six months from collection.	1. If holding times are exceeded for initial or any reanalysis required due to QC excursions, notify the QAO since re-sampling may be required. 2. Document any observation or corrective action in the case narrative.

Table 3-13A. Dimethyl Mercury using USEPA Modified Method 1630 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Initial Calibration **(Accuracy)**	Initial calibration consists of at least five calibration standards (0.128 to 5.12ng/L) and one instrument calibration blank (IBL) following ICV. The lowest calibration point must be at the quantitation limit (QL).	Subtract the peak area of the IBL for each standard. Calculate the calibration factor for Hg in each of the five standards. Criteria for the calibration: 1. RSD ≤ 15%. 2. Recovery for the lowest standard (0.128 ng/L) 65-135%R.	1. If RSD ≤ 15%, calculate sample results using the average response factor. 2. If RSD > 15% or if the recovery of the lowest standard is not in the range of 65-135%, recalibrate the analytical system and repeat the calibration check. 3. Document any observation or corrective action in the case narrative - samples cannot be analyzed until calibration control limit criteria have been met.
Initial Calibration Verification and Continuing Calibration Verification **(ICV/CCV)** **(Accuracy)**	Analyze the ICV after initial calibration and CCV solution (1.57 ng/L) after every 10 analyses and at the end of the sequence.	ICV/CCV Criteria: ICV - Recovery must be within 67-133%. CCV - Recovery must be within 67-133%.	1. Reanalyze. 2. If criteria are still not met, identify and correct problem, recalibrate and re-analyze samples. 3. Document any observation or corrective action in the case narrative – samples cannot be reported until ICV/CCV criteria have been met at the beginning and end of each batch.
Instrument Calibration Blank (ICB) **(Sensitivity)**	Instrument calibration blanks are analyzed to demonstrate freedom from system contamination. The ICB must be analyzed per analytical batch, after ICV.. The blank for an analytical batch, if within acceptance criteria, is subtracted from standard raw data for that batch prior to the calculation of results.	1. If the blank is greater than the RL the system is out of control.	1. The problem must be investigated and remedied, and the associated samples must be reanalyzed. 2. Document any observation or corrective action in the case narrative – samples cannot be analyzed until blank criteria have been met.

Table 3-13A. Dimethyl Mercury using USEPA Modified Method 1630 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Continuing Calibration Blank (CCB) **(Sensitivity)**	CCBs are analyzed to demonstrate freedom from system contamination. The CCB must be analyzed every 10 samples.	1. If the blank is greater than the RL the system is out of control.	1. The problem must be investigated and remedied, and the associated samples must be reanalyzed. 2. Document any observation or corrective action in the case narrative – samples cannot be analyzed until blank criteria have been met.
Method Blank **(Sensitivity)**	Method blanks are used to demonstrate that the analytical system is free from contamination that could otherwise compromise sample results and are prepared and analyzed using sample containers, labware, reagents, and analytical procedures identical to those used to prepare and analyze the samples. A minimum of three method blanks per analytical batch are required.	1. The 3 method blanks must be less than 0.128 ng/L Hg or the system is out of control. 3. The average method blank for an analytical batch, if within acceptance criteria, is subtracted from all raw data for that batch prior to the calculation of results.	1. The problem must be investigated and remedied and samples re-analyzed. 2. Document any observation or corrective action in the case narrative – samples cannot be analyzed until method blank control limit criteria have been met.
Field Blank Analysis **(Sensitivity)**	Field collected - Field blank(s) are samples collected as per the QAPP, from the same site at the same time, to a maximum of 10 samples. Analyze the blank immediately before analyzing the samples in the batch.	1. If Dimethyl mercury is found in the field blank at a concentration equal to or greater than the RL, results for associated samples may be the result of contamination and may not be reported.	If contamination of the field blank and associated samples is known or suspected, the laboratory should communicate this to the sampling team so that the source of contamination can be identified.

Table 3-13A. Dimethyl Mercury using USEPA Modified Method 1630 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Equipment Blank Analysis **(Sensitivity)**	Before any sampling equipment is used at a given site equipment blanks are generated on all sampling equipment that will be used to demonstrate that the sampling equipment is free from contamination. Equipment blanks are generated by processing reagent water through the sampling devices using the same procedures that are used in the field. Therefore, the "clean hands/dirty hands" technique used during field sampling should be followed when preparing equipment blanks at the laboratory or cleaning facility for low level mercury measurements.	1. Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous samples: cooler temperature ≤6°C. For solid samples: cooler temperature ≤6°C, See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Method Summary - Total Mercury in Aqueous or Solid Media, USEPA Modified Method 1631, Based on Eurofins Frontier Global Sciences SOP **EFASF-T-AFS-SOP2822**	Total mercury is measured by Flow Injection Atomic Fluorescence Spectrometry (AFS). Total mercury includes all bromine monochloride-oxidizable mercury forms found in an unfiltered aqueous solution. This includes, but is not limited to, Hg(II), Hg(0), strongly organo-complexed Hg(II) compounds, adsorbed particulate Hg (P), and several tested covalently bound organo-mercurials (e.g., CH_3HgCl, $(CH_3)_2Hg$, and $C_6H_5HgOOCCH_3$). The recovery of Hg bound within microbial cells may require the additional preparation. Aqueous samples are collected directly into a rigorously cleaned, pretested, polyethylene terephthalate glycol-modified (PETG) bottle using sample handling techniques designed for collection of mercury at trace levels. Aqueous samples are preserved upon receipt at the laboratory with 0.2N BrCL (pre-tested for mercury). Solid samples are collected into clean wide mouth glass or high density polyethylene or glass jars with Teflon-lined caps and are preserved by freezing to -11 °C upon receipt. Maximum holding time is 180 days. Solid samples are digested using modified EPA 1631b Aqua-Regia. Prior to analysis, Hg is oxidized to Hg(II). After oxidation, the sample is sequentially reduced with NH_2OH-HCl to destroy the free halogens, then reduced with stannous chloride (SnCl2) to convert Hg(II) to volatile Hg(0). The Hg(0) is separated from solution by purging with argon. The Hg(0) is collected onto traps, thermally desorbed from the analytical trap into a gas stream that carries the Hg into the an AFS for detection. Quality is assured through calibration and testing of the oxidation, purging, and detection systems.	
Selective Sequential Extraction of Geological Samples for Mercury Fractionation	Extraction fraction procedure to determine the following: Volatile Free Elemental Mercury (Hg^0) F-1 Water Soluble Mercury (solid samples only) F-2 pH 2 Soluble Mercury (solid samples only) F-3 1N KOH Extractable Mercury (solid samples only) F-4-12N HNO3 Soluble Mercury (solid samples only) F-5-Aqua Regia Soluble Mercury (solid samples only) F-6 Mineral-Bound Mercury (solid samples only) F-S Total Mercury by Sum of Species (solid samples only)		

Table 3-14. Mercury using USEPA Modified Method 1631 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Holding times (Sensitivity)	Samples must be digested and analyzed within holding time.	Aqueous samples are collected directly into a rigorously cleaned, pretested, polyethylene terephthalate glycol-modified (PETG) bottle using sample handling techniques designed for collection of mercury at trace levels. Aqueous samples are preserved (oxidized) upon receipt at the laboratory with 0.2N BrCL (pre-tested for mercury). Samples must be either preservedwithin 48 hours of collection unless preservation occurs with the original bottle of which preservation needs to occur within 28 days. Solid samples are collected into wide mouth glass or high density polyethylene or fluoropolymer jars and are preserved by freezing upon receipt. Solid samples must be analyzed 180 days from collection.	1. If holding times are exceeded for initial or any reanalysis required due to QC excursions, notify the QAO since re-sampling may be required. 2. Document any observation or corrective action in the case narrative.
Initial Calibration **(Accuracy)**	Initial calibration consists of at least five calibration standards (0.5 to 40 ng/L) and three instrument calibration blanks (IBLs). The lowest calibration point must be at the quantitation limit (QL) or below the QL.	Subtract the average peak area of the IBL for each standard and sample. Calculate the calibration factor for Hg in each of the five standards. Criteria for the calibration: 1. RSD ≤ 15%. 2. Recovery for the lowest standard (0.5 ng/L) 75-125%R.	1. If RSD ≤ 15%, calculate sample results using the average response factor. 2. If RSD > 15% or if the recovery of the lowest standard is not in the range of 75-125%, recalibrate the analytical system and repeat the calibration check. 3. Document any observation or corrective action in the case narrative - samples cannot be analyzed until calibration control limit criteria have been met.
Initial Calibration Verification and Calibration Verification **(ICV/CCV)** **(Accuracy)**	Analyze the ICV after initial calibration and CCV solution (5 ng/L) after every 10 analyses and at the end of the sequence.	ICV/CCV Criteria: ICV - Recovery must be within 79-121%. CCV - Recovery must be within 77-123%.	1. Reanalyze in duplicate. 2. If criteria are still not met, identify and correct problem, recalibrate and re-analyze samples. 3. Document any observation or corrective action in the case narrative – samples cannot be reported until ICV/CCV criteria have been met at the beginning and end of each batch.

Table 3-14. Mercury using USEPA Modified Method 1631 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Instrument Calibration Blank (ICB) **(Sensitivity)**	Instrument calibration blanks are analyzed to demonstrate freedom from system contamination. At least three blanks must be run per analytical batch, prior to calibration standards. The average blank for an analytical batch, if within acceptance criteria, is subtracted from all raw data for that batch prior to the calculation of results.	1. If the blank is found to contain more than 0.5 ng/L Hg, the system is out of control. 2. The mean instrument blank must be ≤0.25 ng/L with a standard deviation of 0.1 ng/L.	1. The problem must be investigated and remedied, and the associated samples must be reanalyzed. 2. Document any observation or corrective action in the case narrative – samples cannot be analyzed until blank criteria have been met.
1% BrCl Method Blank **(Sensitivity)**	1% BrCl method blanks are used to demonstrate that the analytical system is free from contamination that could otherwise compromise sample results and are prepared and analyzed using sample containers, labware, reagents, and analytical procedures identical to those used to prepare and analyze the samples. A minimum of three 1% BrCl method blanks per analytical batch are required.	1. If the result for any method blank containing the nominal amount of reagent used to prepare a sample is found to contain > 0.50 ng/L Hg, the system is out of control. 2. Mercury in the analytical system must be reduced until a method blank is free from contamination at the 0.50 ng/L level. Samples associated with a contaminated method blank must be reanalyzed.	1. The problem must be investigated and remedied and samples re-analyzed. 2. Document any observation or corrective action in the case narrative – samples cannot be analyzed until method blank control limit criteria have been met.
Field Blank Analysis **(Sensitivity)**	Field collected - Field blank(s) are samples collected as per the QAPP, from the same site at the same time, to a maximum of 10 samples. Analyze the blank in the same batch as the samples at the beginning.	1. If Hg is found in the field blank at a concentration equal to or greater than the RL, results for associated samples may be the result of contamination and may not be reported.	If contamination of the field blank and associated samples is known or suspected, the laboratory should communicate this to the sampling team so that the source of contamination can be identified.

Table 3-14. Mercury using USEPA Modified Method 1631 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Equipment Blank Analysis **(Sensitivity)**	Before any sampling equipment is used at a given site equipment blanks are generated on all sampling equipment that will be used to demonstrate that the sampling equipment is free from contamination. Equipment blanks are generated by processing reagent water through the sampling devices using the same procedures that are used in the field. Therefore, the "clean hands/dirty hands" technique used during field sampling should be followed when preparing equipment blanks at the laboratory or cleaning facility for low level mercury measurements.	1. If Hg is found in the equipment blank at a concentration equal to or greater than the RL, results for associated samples may be the result of contamination and may not be reported.	If contamination of the equipment blank and associated samples is known or suspected, the laboratory should communicate this to the sampling team so that the source of contamination can be identified.
Quality Control Sample (QCS) / Laboratory Control Sample Analysis / **LCSD** **(Accuracy)**	Prepared independently from calibration standards at mid-point of the concentration range or at the CCV concentration and analyzed at the mid-point of the analytical batch.	Recovery must be within 80-120%. RPD must be ≤24	1. Reanalyze LCS and examine results of other QC analyses. 2. If other QC criteria have not been met, stop analysis, locate and correct problem, recalibrate and reanalyze samples since last satisfactory LCS. 3. Document any observation or corrective action in the case narrative.
Ongoing Precision and Recovery (OCR) Analysis **(Accuracy)**	Prepared independently from calibration standards and analyzed at the beginning and end of each analytical batch.	Recovery must be within 77-123%.	1. Reanalyze and examine results of other QC analyses. 2. If other QC criteria have not been met, stop analysis, locate and correct problem, recalibrate and reanalyze samples since last satisfactory OCR. 3. Document any observation or corrective action in the case narrative.
Matrix Spike Analysis / Matrix Spike Duplicate **(Accuracy and Precision)**	One for each batch of 10 samples of similar matrix.	1. Recovery must be within 71-125%. 2. RPD must be ≤24	1. Reanalyze and examine results of other QC analyses. 2. Document any observation or corrective action in the case narrative.

Table 3-14. Mercury using USEPA Modified Method 1631 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Field Duplicate Analysis **(Precision)**	Collected per the QAPP	Validation criteria: 30% RPD for waters, 50% RPD for solids. For sample results that are less than or equal to five times the RL, the criterion of plus or minus two times the RL will be applied to evaluate field duplicate.	No corrective action required of the laboratory since the laboratory will not know the identity of the field duplicate samples. If these criteria are not met, sample results will be evaluated on a case-by-case basis.
Laboratory control limits	Generated with results for an analyte from a minimum of 5-10 sample analyses. The average of the sample results and the standard deviation are calculated. The internal warning limits are established at 2 times the standard deviation and the control limits are established at 3 times the standard deviation. The control limits are updated annually.	Not applicable	Not applicable
MDL Determination	Each time this Method is modified, the laboratory is required to repeat the procedure to demonstrate that an MDL (40 CFR Part 136, Appendix B) less than or equal to one-third the regulatory compliance level or less than or equal to the MDL of this Method, whichever is greater, can be achieved.	Not applicable	Not applicable

Table 3-14. Mercury using USEPA Modified Method 1631 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Preparation Batch / Analytical Run	An analytical run is a set of samples/QC prepared with the same batch of analytical reagents, and analyzed during the same 12-hour shift. For a water preparation batch may be from 1 to 20 samples and only the method blanks with the samples as this is a preservation step only. The LCS/LCSD, analytical duplicates and analytical matrix spikes/spike duplicates are created during the analytical run for the matrix A solid preparation batch may be from 1 to 20 samples. Each batch must be accompanied by at least three blanks, a LCS/LCSD, . In addition, there must be one MS and one MSD sample for every 10 samples (a frequency of 10%).	Not applicable	Not applicable
Sample Batching	The laboratory will batch project samples together along with QC samples specified from the project. Non-project information will not be included in the data packages.	Not applicable	Not applicable
Dilutions	When target analyte concentration exceed upper limit of calibration curve. When matrix interference demonstrated by lab and documented in the case narrative. Laboratory will note in the data deliverables which analytical runs were reported.	Not applicable	Not applicable

Table 3-14. Mercury using USEPA Modified Method 1631 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Deliverables as required	Full NJDEP deliverables must be provided to document each audit item for easy reference and inspection. An example calculation will be provided for each analysis, for each type of matrix in the data package using samples from the project. Any laboratory abbreviations or notations presented in the raw data or summary information will be explained or referenced in the case narrative. Final spiking concentrations will be presented in summary form. Standard tracing information will be provided. Cooler temperatures will be provided in the data packages. Run logs will be provided in the data packages.	Not applicable	Provide missing or additional deliverables for validation purposes.
Method and QAPP requirements	The laboratory will perform the method as presented in this QAPP and will adhere to the QAPP requirements presented herein. Otherwise the laboratory will specifically note any procedures that differ from the method or the QAPP in the data package case narrative.	Not applicable	Not applicable

Note

Data validation will be performed in accordance with QA/QC criteria established in these tables and the analytical methods that are currently used by the laboratory. Excursions from QA/QC criteria will be qualified based on guidance provided in this QAPP.

Communications with the QAO will be documented and included in the data packages.

Source: O'Brien & Gere

Table 3-15. Arsenic Speciation using USEPA Modified Method 1632 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous samples: cooler temperature ≤6°C. For solid samples: cooler temperature ≤6°C. See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Method Summary – Arsenic Speciation or Solid Media, USEPA Modified Method 1632, Based on Eurofins Frontier Global Sciences SOP **EFAFS-T-AFS-SOP2987**	Arsenic Speciation in aqueous and solids by Hydride Generation Cryogenic Trapping Gas Chromatography- Atomic Absorption Spectrophotometry (HG-CT-GC-AAS). Applied to arsenite [As(III)], total inorganic arsenic (TIA), and arsenate [As(V)] by calculation. Arsenic species (TIAs/MMA/DMA) are selectively volatilized from solution by controlling the pH then reducing to corresponding hydrides with borohydride in the reaction vessel. The arsines are purged from the solution by a helium gas flow then trapped onto a liquid nitrogen cooled 'U' column. Heating the column re-volatilizes the arsines and allows for chromatographic separation based on increasing boiling points. The arsines are carried into a quartz furnace with a hydrogen-air flame where they are atomized and detected via atomic absorption spectrophotometry. The elution order is as follows: TIAs eluting first and MMA and DMA a several minutes later. As(III) is selectively volatilized from solution by adding a tris buffer to the reaction vessel.		
Holding times (Sensitivity)	Samples must be digested and analyzed within holding time.	Aqueous samples are acidified to pH <2 with hydrochloric acid and stored in polyethylene bags at 0-6°C from the time of collection until analysis. Analyze 28 days from collection. Solid samples are collected into plastic zip type bags (double bagged) or wide-mouth jars with Teflon lined lids. Analyze 180 days from collection at < -11 °C.	1. If holding times are exceeded for initial or any reanalysis required due to QC excursions, notify the QAO since re-sampling may be required. 2. Document any observation or corrective action in the case narrative.
Initial Calibration **(Accuracy)**	Initial calibration consists of at least three calibration standards (0.01 to 0.5 µg/L) for arsenite (AsIII) and total inorganic arsenic (TIAs) and one instrument calibration blank (IBL) following ICV. The lowest calibration point must be at the quantitation limit (QL).	Calculate the calibration factor for Hg in each of the three standards. Criteria for the calibration: 1. RSD ≤ 20% or correlation coefficient ≥ 0.995.	1. If RSD ≤ 20% or correlation coefficient ≥ 0.995, calculate sample results using the average response factor. 2. If RSD > 20% or correlation coefficient < 0.995 recalibrate the analytical system and repeat the calibration check. 3. Document any observation or corrective action in the case narrative - samples cannot be analyzed until calibration control limit criteria have been met.

Table 3-15. Arsenic Speciation using USEPA Modified Method 1632 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Initial Calibration Verification and Calibration Verification **(ICV/CCV)** **(Accuracy)**	Analyze the ICV after initial calibration and CCV solution at mid-level concentration after every 10 analyses and at the end of the sequence.	ICV/CCV Criteria: As III/– ICV/CCV - Recovery must be within 70-130%. TIAs (Total Inorganic Arsenic)/– ICV/CCV - Recovery must be within 80-120%.	1. Reanalyze. 2. If criteria are still not met, identify and correct problem, recalibrate and re-analyze samples. 3. Document any observation or corrective action in the case narrative – samples cannot be reported until ICV/CCV criteria have been met at the beginning and end of each batch.
Instrument Calibration Blank (ICB) **(Sensitivity)**	Instrument calibration blanks are analyzed to demonstrate freedom from system contamination.	1. If the blank is greater than the RL the system is out of control.	1. The problem must be investigated and remedied, and the associated samples must be reanalyzed. 2. Document any observation or corrective action in the case narrative – samples cannot be analyzed until blank criteria have been met.
Method Blank **(Sensitivity)**	Method blank is used to demonstrate that the analytical system is free from contamination that could otherwise compromise sample results and is prepared and analyzed using sample containers, labware, reagents, and analytical procedures identical to those used to prepare and analyze the samples.	The method blanks must be less than the RL or the system is out of control.	1. The problem must be investigated and remedied and samples re-analyzed. 2. Document any observation or corrective action in the case narrative – samples cannot be analyzed until method blank control limit criteria have been met.
Field Blank Analysis **(Sensitivity)**	Field collected - Field blank(s) are samples collected as per the QAPP, from the same site at the same time, to a maximum of 10 samples. Analyze the blank immediately before analyzing the samples in the batch.	If found in the field blank at a concentration equal to or greater than the RL, results for associated samples may be the result of contamination and may not be reported.	If contamination of the field blank and associated samples is known or suspected, the laboratory should communicate this to the sampling team so that the source of contamination can be identified.

Table 3-15. Arsenic Speciation using USEPA Modified Method 1632 quality control requirements and corrective actions

Audit	Frequency	Control Limits	Corrective Action
Equipment Blank Analysis **(Sensitivity)**	Before any sampling equipment is used at a given site equipment blanks are generated on all sampling equipment that will be used to demonstrate that the sampling equipment is free from contamination.	1. If found in the equipment blank at a concentration equal to or greater than the RL, results for associated samples may be the result of contamination and may not be reported.	If contamination of the equipment blank and associated samples is known or suspected, the laboratory should communicate this to the sampling team so that the source of contamination can be identified.
Quality Control Sample (QCS) / Laboratory Control/LCSD Sample Analysis **(Accuracy)**	Prepared independently from calibration standards at mid-point of the concentration range or at the CCV concentration and analyzed at the mid-point of the analytical batch.	As III – Recovery must be within 30-170%. RPD <35.	1. Reanalyze LCS and examine results of other QC analyses. 2. If other QC criteria have not been met, stop analysis, locate and correct problem, recalibrate and reanalyze samples since last satisfactory LCS. 3. Document any observation or corrective action in the case narrative.
Matrix Spike Analysis/Matrix Spike Duplicate **(Accuracy and Precision)**	One for each batch of 10 samples of similar matrix.	As III – Recovery must be within 30-170%. RPD <35.	1. Reanalyze and examine results of other QC analyses. 2. Document any observation or corrective action in the case narrative.
Field Duplicate Analysis **(Precision)**	Collected per the QAPP	Validation criteria: 30% RPD for waters, 50% RPD for solids. For sample results that are less than or equal to five times the RL, the criterion of plus or minus two times the RL will be applied to evaluate field duplicate.	No corrective action required of the laboratory since the laboratory will not know the identity of the field duplicate samples. If these criteria are not met, sample results will be evaluated on a case-by-case basis.

Table 3-16. AVS/SEM using USEPA 821-R-91-100 quality control requirements and corrective actions.

Audit Parameter (DQI)	Frequency	Control Limits	Corrective Action
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous and solid samples: cooler temperature ≤6°C. See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Holding times (Sensitivity)	Samples must be prepared and analyzed within holding time.	1. Preserve at 4°C (± 2°C) as soon as possible after sample collection. 2. Analyze within 14 days from collection. 3. Sulfide ion is unstable in the presence of oxygen. Protect samples from exposure to oxygen during sample collection and handling. 4. During storage sulfide can be formed or lost due to biological activity and sulfide can be lost by volatilization or oxidation. Metal species can change as a result of changes in sulfide concentration and as a result of other changes to the sample. 5. Samples should be collected in wide mouth jars with a minimum of air space above the sediment. If possible, the headspace should be filled with oxygen-free nitrogen or argon. The jar lids must have Teflon or polyethylene liners.	If holding times are exceeded for initial or any re-analyses required due to QC excursions, notify QAO since re-sampling may be required. Document corrective action in the case narrative.
Calibration for AVS (Accuracy)	Initial calibration using five standard calibration curve every three months. Continuing calibration analyzed with each sample batch.	90-110 % Recovery	1. Reanalyze. 2. If criteria are still not met, identify and correct problem, recalibrate. 3. Document corrective action in the case narrative - samples cannot be analyzed until calibration control limit criteria have been met.

Table 3-16. AVS/SEM using USEPA 821-R-91-100 quality control requirements and corrective actions.

Audit Parameter (DQI)	Frequency	Control Limits	Corrective Action
Calibration for SEM- Metals **(ICV, CCV)** **(Accuracy)**	Calibrate daily or once every 24 hours using a blank and at least three standards. An ICV is analyzed following the calibration using an independent standard at a concentration within the calibration range. A CCV standard at the mid-range level concentration, is analyzed at the beginning of the run, every 2 hours or at a frequency of 10%, and at the end of each run.	90-110 % Recovery	1. Reanalyze. 2. If criteria are still not met, identify and correct problem, recalibrate. 3. Document corrective action in the case narrative - samples cannot be analyzed until calibration control limit criteria have been met.
SEM- LLQC Standard for ICP. **(Accuracy)**	For ICP, spiked at the Reporting Limit.	70-130% recovery	1. If recovery is outside of 70-130 % Recovery, stop analysis. 2. Identify and correct problem, recalibrate if necessary, re-verify calibration, and reanalyze affected samples.
SEM- Calibration **Blank** **(Sensitivity)**	ICB must be analyzed after ICV. CCB must be analyzed after CCV, at beginning and end of run and at a rate of 10% or every 2 hours during analysis sequence.	Evaluate whether ICB or CCB exceeds the RL.	If CCB or ICB exceeds the RL, stop analysis. Identify and correct problem, recalibrate and reanalyze affected samples. Document corrective action - **samples cannot be analyzed until blank criteria have been met.**
AVS- Preparation Blank Analysis **(Sensitivity)**	One prepared with every batch of samples prepared.	Evaluate whether preparation blank exceeds the RL.	1. If preparation blank exceeds the RL, stop analysis. 2. Identify and correct problem, re-prepare and reanalyze affected samples. Document corrective action - **samples cannot be analyzed until blank criteria have been met.**

Table 3-16. AVS/SEM using USEPA 821-R-91-100 quality control requirements and corrective actions.

Audit Parameter (DQI)	Frequency	Control Limits	Corrective Action
SEM- Preparation Blank Analysis **(Sensitivity)**	One prepared with every batch of samples prepared.	Evaluate whether ICB or CCB exceeds the RL.	1. If preparation blank exceeds the RL, and if concentration of the analyte in the associated samples is greater than the RL and less than 10 times the blank concentration, stop analysis. 2. If preparation blank is less than the negative RL, and the concentration of the analyte in the associated samples is less than 10 times the RL, stop analysis 3. Identify and correct problem, re-prepare and reanalyze affected samples. Document corrective action - **samples cannot be analyzed until blank criteria have been met.**
Field/ **Equipment Blank Analysis** **(Sensitivity)**	At the frequency listed in the QAPP.	Evaluate whether blank exceeds the RL.	blank exceeds the RL investigate problem and contact QAO. ocument in case narrative.
AVS- LCS Analysis **(Accuracy)**	Every 20 samples or each preparation batch. Prepared independently from calibration standards.	Recovery must be within laboratory control limits. If laboratory limits not established, use 85-105 %Recovery.	If recovery is outside of 50 –150 %Recovery, stop analysis. Correct problem. Re-prepare and reanalyze samples since last satisfactory LCS. Document corrective action.
SEM- LCS Analysis **(Accuracy)**	Every 20 samples or each preparation batch. Prepared independently from calibration standards.	Recovery must be within laboratory control limits.	1. If recovery is outside of 50 –150 %Recovery, stop analysis. 2. Correct problem. - prepare and reanalyze samples since last satisfactory LCS. - Document corrective action.
SEM- ICP Serial Dilution Analysis **(Accuracy)**	Every group of samples of similar matrix. Only required when analyte concentration is >50 times the IDL in the original sample.	Must agree within 10% of the original determination.	Report result

Table 3-16. AVS/SEM using USEPA 821-R-91-100 quality control requirements and corrective actions.

Audit Parameter (DQI)	Frequency	Control Limits	Corrective Action
SEM- ICP Interference Check Sample Analysis **(Accuracy)**	Beginning and end of each analytical run or twice during every 8 hours, whichever is more frequent for ICP.	Results for Solution AB – 80-120% Recovery	Stop analysis. Correct problem and recalibrate. Reanalyze samples analyzed since last satisfactory ICS. Document corrective action.
AVS- MS/MSD Analysis **(Accuracy and Precision)**	One per group of similar concentration and matrix, every 20 samples.	If spike concentration is greater than 10% of the un-spiked sample concentration, recovery must be within laboratory control limits. If laboratory limits not established, use 85-105 %Recovery.	If recovery is outside of 50 –150 %Recovery, stop analysis. Investigate. Re-prepare and reanalyze samples one time. Document corrective action.
SEM- MS/MSD Analysis **(Accuracy and Precision)**	One per group of similar concentration and matrix.	If sample concentration does not exceed the spike concentration by a factor of four or more, 75-125% Recovery	If recovery is outside of 50-150 % Recovery, reanalyze. For ICP, if recovery is outside of 75-125 % Recovery, analyze post-digestion spike at two times the CRRL or two times the indigenous level, whichever is greater. Document corrective action.
SEM- MS/MSD or Laboratory Duplicate Analysis **(Precision)**	One per group of similar concentration and matrix.	20% RPD for values greater than or equal to 5 times the RL. For values less than 5 times the CRRL, .± the RL	Report result.
Field Duplicate Analysis **(Precision)**	At the frequency listed in the QAPP.	Validation criteria: 30% RPD for waters, 50% RPD for solids. For sample results that are less than or equal to five times the RL, the criterion of plus or minus two times the RL will be applied to evaluate field duplicates.	No corrective action required of the laboratory since the laboratory will not know the identity of the field duplicate samples. If these criteria are not met, sample results will be evaluated on a case by case basis during the validation process.
AVS- colorimetric method procedure	Between 30 minutes and 120 minutes after adding mixed diamine reagent to develop the color, measure the absorbance.	If the absorbance is greater than 0.6, dilute 10f-fold and compare to the high range concentration curve.	NA
AVS- MDL or IDL Determination	Performed annually	Prepared as per method	NA
SEM- IDL Determination	Within 30 days of the start of analysis and semiannually.	Prepared as per method.	NA

Table 3-16. AVS/SEM using USEPA 821-R-91-100 quality control requirements and corrective actions.

Audit Parameter (DQI)	Frequency	Control Limits	Corrective Action
AVS - Linear Range Analysis	Not required for AVS	Performed as per method	NA
SEM- Linear Range Analysis	Every 6 months.	Within 5% of the true value.	NA
SEM- Interelement Correction For ICP	Within 6 months of the start of analysis and annually. Correction factors for Al, Ca, Fe, and Mg must be reported and for others if they are applied.	As per method procedures.	NA
Sample Batching	The laboratory will batch project samples together along with QC samples specified from the project. Non-project information will not be included in the data packages.	Not applicable	1. Identify and correct problem. 2. If criteria are still not met, recalibrate. 3. Document corrective action in the case narrative 4. Samples cannot be analyzed until blank control limit criteria have been met.
Dilutions	Dilute and reanalyze samples with concentrations that are greater than the linear range of the instrument or method technique. The laboratory will note in the data package which analytical runs were used to report the sample results.	Not applicable	Not applicable. .
Sample Batching	The laboratory will batch project samples together along with QC samples specified from the project. Non-project information will not be included in the data packages.	Not applicable	Not applicable
Laboratory control limits	Generated with results for an analyte from a minimum of 20 sample analyses. The average of the sample results and the standard deviation are calculated. Table 3-17. Nitrate and Nitrite using USEPA Methods 9056A, 353.2 and 300.0 quality control requirements and corrective actions

Audit (Where applicable)	Frequency (Where applicable)	Control Limits (Where applicable)	Corrective Action (Where applicable)
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous and solid samples: cooler temperature ≤6°C, See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Holding Times	Samples must be prepared and analyzed within holding time.	Nitrate, Nitrite: Analyze 48 hours from collection.	1. If holding times are exceeded for initial or any reanalysis required due to QC excursions, notify the QAO since re-sampling may be required. 2. Document corrective action in the case narrative.
Initial Calibration	Three to six point calibration standards prior to sample analysis. One standard must be at the QL concentration.	Linear calibration using response factor with RSD less than or equal to 10%. If RSD <10% the average calibration factor (external calibration) is used for quantitation. For compounds with RSD greater than 10% use linear calibration that does not pass through the origin with least squares regression (r for un-weighted least squares regression, Coefficient of Determination or r2 must be greater than 0.990) or non-linear calibration using no more than third order with seven standards, (COD or r2 must be greater than 0.990).	1. Reanalyze. 2. If criteria are still not met, identify and correct problem, recalibrate. 3. Document corrective action in the case narrative - samples cannot be analyzed until calibration control limit criteria have been met.
Initial and Continuing Calibration Verification **(ICV, CCV)**	ICV analyzed following calibration and CCV after every 10 samples and at the end of the sequence. CCV is also analyzed daily in lieu of a full initial calibration.	ICV, CCV recovery must be within 90-110% of the true value.	1. Reanalyze. 2. If criteria are still not met, identify and correct problem, recalibrate. 3. Document corrective action in the case narrative - samples cannot be analyzed until calibration control limit criteria have been met.

Table 3-17. Nitrate and Nitrite using USEPA Methods 9056A, 353.2 and 300.0 quality control requirements and corrective actions

Audit (Where applicable)	Frequency (Where applicable)	Control Limits (Where applicable)	Corrective Action (Where applicable)
Initial and Continuing Calibration Blank (ICB/CCB)	After ICV/CCV at beginning and end of run and at a rate of 10%.	The absolute value of the ICB and CCB must not exceed the QL.	1. Identify and correct problem. 2. If criteria are still not met, recalibrate and reanalyze affected samples. 3. Document corrective action in the case narrative - samples cannot be analyzed until blank control limit criteria have been met.
Preparation Blank Analysis	1 per batch of samples prepared or 1 in 20, whichever is greater.	The absolute value of the method blank must not exceed the QL. Preparation blank for turbidity and color interference check is subtracted for phosphate analysis.	1. Reanalyze blank. 2. If limits are still exceeded, re-prepare and reanalyze affected samples. 3. Document corrective action in the case narrative - samples cannot be analyzed until blank criteria are met.
Laboratory Control Sample Analysis	Every 20 samples or each preparation batch. Prepared independently from calibration standards.	Recovery within laboratory control limits. The lowest acceptable control limits for recovery will be 10%.	1. Reanalyze LCS and examine results of other QC analyses. 2. If recovery is still outside limits, and other QC criteria are met, report both runs. 3. If other QC criteria have not been met, stop analysis, locate and correct problem, reanalyze samples since last satisfactory LCS. 4. Document corrective action in the case narrative.
Matrix Spike Analysis	Collected at the frequency listed in the QAPP. Samples from the investigation must be used for MS/MSD or MS/Duplicate analysis.	Recovery within laboratory control limits or 75-125%. Recovery does not apply if sample concentration > 4 X spike concentration. Spike must contain all analytes. The lowest acceptable laboratory control limits for recovery will be 10%.	1. If LCS criteria are met, document in the case narrative. 2. If LCS criteria are not met, examine other QC data to identify the source of the problem. 3. Re-prepare/ reanalyze samples associated with the matrix spike and LCS. 4. Document corrective action.

Table 3-17. Nitrate and Nitrite using USEPA Methods 9056A, 353.2 and 300.0 quality control requirements and corrective actions

Audit (Where applicable)	Frequency (Where applicable)	Control Limits (Where applicable)	Corrective Action (Where applicable)
Laboratory Duplicate or Matrix Spike Duplicate Analysis	Collected at the frequency listed in the QAPP. Samples from the investigation must be used for Laboratory Duplicate and MSD analysis	RPD within laboratory control limits or 20% for RPD shall be used for original and duplicate sample values greater than or equal to five times the QL. A control limit of the QL value shall be used if either the sample or duplicate value is less than five times the CRQL.	1. Investigate problem and reanalyze. 2. Document corrective action.
Field/Equipment Blank Analysis	Collected at the frequency listed in the QAPP.	Less than QL	1. Investigate problem. 2. Document in the case narrative.
Field Duplicate Analysis	Collected at the frequency listed in the QAPP. The field duplicate identification will not be provided to the laboratory.	Validation criteria: 50% RPD for waters. For sample results that are less than or equal to five times the QL, the criterion of plus or minus two times the QL will be applied to evaluate field duplicates.	No corrective action required of the laboratory since the laboratory will not know the identity of the field duplicate samples. If these criteria are not met, sample results will be evaluated on a case-by-case basis.
Sample Batching	The laboratory will batch project samples together along with QC samples specified from the project. Non-project information will not be included in the data packages.	Not applicable	Not applicable
Dilutions	1. Dilute and reanalyze samples with concentrations that are greater than the linear range of the instrument. 2. The laboratory will note in the data package which analytical runs were used to report the sample results.	Not applicable	Not applicable. .

Audit (Where applicable)	Frequency (Where applicable)	Control Limits (Where applicable)	Corrective Action (Where applicable)
Deliverables	1.Full NJDEP deliverables must be provided to document each audit item for easy reference and inspection. 2. An example calculation may be requested for each analysis, for each type of matrix in the data package using samples from the project. 3. Any laboratory abbreviations or notations presented in the raw data or summary information will be explained or referenced in the case narrative. 4. Final spiking concentrations will be presented in summary form. 5. Standard tracing information will be provided. 6. Cooler temperatures will be provided in the data packages. 7. Run logs will be provided in the data packages.	Not applicable	Provide missing or additional deliverables for validation purposes.
Method and QAPP requirements	The laboratory will perform the method as presented in this QAPP and will adhere to the QAPP requirements presented herein. Otherwise the laboratory will specifically note any procedures that differ from the method or the QAPP in the data package case narrative.	Not applicable	Not applicable

Note

Data validation will be performed in accordance with QA/QC criteria established in these tables and the analytical methods. Excursions from QA/QC criteria will be qualified based on guidance provided in this QAPP.

Communications with O'Brien & Gere will be documented and included in the data packages.

Source: O'Brien & Gere

Table 3-18. Ammonia using USEPA Method 350.1 quality control requirements and corrective actions.

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous and soil samples: cooler temperature 4°C, H_2SO_4 to pH<2. See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Holding times (Sensitivity)	Samples must be prepared and analyzed within holding time.	Ammonia: Analyze 28 days from collection.	1. If holding times are exceeded for initial or any re-analyses required due to QC excursions, notify the Quality Assurance Officer (QAO) since re-sampling may be required.
Initial Calibration and Calibration Verification **(ICV, CCV)** **(Accuracy)**	At a minimum three to six standards (depending on method requirements) and a blank, prior to sample analysis and when calibration verification criteria are not met.. One standard must be at the QL concentration. ICV accompanies each initial calibration. CCV is analyzed following calibration, after every 10 samples and at the end of the sequence to bracket sample analyses.	Linear calibration using response factor with RSD less than or equal to 10%. If RSD <10% the average calibration factor (external calibration) is used for quantitation. For compounds with RSD greater than 10% use linear calibration that does not pass through the origin with least squares regression (r for un-weighted least squares regression, Coefficient of Determination or r2 must be greater than 0.995) or non-linear calibration using no more than third order with seven standards, (COD or r2 must be greater than 0.995). For ICV, CCV - 90% to 110% of expected value.	1. Reanalyze. 2. If criteria are still not met, identify and correct problem, recalibrate. 3. Document corrective action in the case narrative - samples cannot be analyzed until calibration criteria have been met.
Calibration Blank **(Sensitivity)**	At beginning and end of run and at a rate of 10% during run.	The absolute value of the target analyte must be less than QL.	1. Identify and correct problem. 2. If criteria are still not met, recalibrate. 3. Document corrective action in the case narrative 4. Samples cannot be analyzed until blank control limit criteria have been met.

Table 3-18. Ammonia using USEPA Method 350.1 quality control requirements and corrective actions.

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Preparation / Method Blank Analysis **(Sensitivity)**	1 per batch of samples prepared in the sample batch.	Target analytes less than QL.	1. Reanalyze blank. 2. If limits are still exceeded, clean instrument and recalibrate analytical system and re-preparation and reanalyze affected samples if detected. 3. Document corrective action - samples cannot be analyzed until blank criteria are met.
Laboratory Control Sample Analysis **(Accuracy)**	Every 20 samples or each preparation batch. Prepared independently from calibration standards.	Recovery within laboratory control limits or 80% to 120%. The lowest acceptable control limits for recovery will be 10%.	1. If recovery failures are above control limits and these target analytes are not detected in the associated samples, no corrective action is required. 2. If recovery failures are below the control limits, reanalyze LCS and examine results of other QC analyses. 3. If other QC criteria have not been met, stop analysis, locate and correct problem, recalibrate instrument and reanalyze samples since last satisfactory LCS. 4. Document corrective action in the case narrative.
Matrix Spike Analysis **(Accuracy**	Collected per project requirements. Samples from the investigation must be used for MS/MSD analysis. If samples were not designated as MS/MSD samples, contact QAO upon receipt of samples at the laboratory.	Recovery within laboratory control limits or 75-125%. Recovery does not apply if sample concentration > 4 X spike concentration. Spike must contain all analytes. The lowest acceptable laboratory control limits for recovery will be 10%.	1. Document corrective action in the case narrative.

Table 3-18. Ammonia using USEPA Method 350.1 quality control requirements and corrective actions.

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Laboratory Duplicate or Matrix Spike Duplicate Analysis **(Precision)**	Collected per project requirements. Samples from the investigation must be used for Laboratory Duplicate and MSD analysis. If samples were not designated as QC samples, contact QAO upon receipt of samples at the laboratory.	Laboratory control limit or 20% for RPD shall be used for original and duplicate sample values greater than or equal to five times the QL. A control limit of the QL value shall be used if either the sample or duplicate value is less than five times the QL.	1. Investigate problem and reanalyze. 2. Document corrective action in the case narrative.
Field / Equipment Blank Analysis **(Sensitivity)**	Collected per project requirements.	Target analytes less than QL.	1. Investigate problem. 2. Document in the case narrative.
Field Duplicate Analysis **(Precision)**	Collected per project requirements.	Validation criteria: 50% RPD for waters, 100% RPD for solids. For sample results that are less than or equal to five times the QL, the criterion of plus or minus two times the QL will be applied to evaluate field duplicates.	No corrective action required of the laboratory since the laboratory will not know the identity of the field duplicate samples. If these criteria are not met, sample results will be evaluated on a case-by-case basis.
Dilutions	Dilute and reanalyze samples with concentrations that are greater than the linear range of the instrument or method technique. The laboratory will note in the data package which analytical runs were used to report the sample results.	Not applicable	Not applicable. .
Sample Batching	The laboratory will batch project samples together along with QC samples specified from the project. Non-project information will not be included in the data packages.	Not applicable	Not applicable

Table 3-18. Ammonia using USEPA Method 350.1 quality control requirements and corrective actions.

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Laboratory control limits	Generated with results for an analyte from a minimum of 20 sample analyses. The average of the sample results and the standard deviation are calculated. The internal warning limits are established at 2 times the standard deviation and the control limits are established at 3 times the standard deviation. The control limits are updated annually.	Not applicable	Not applicable
Deliverables as required	Full NJDEP deliverables must be provided to document each audit item for easy reference and inspection. An example calculation may be requested for each analysis, for each type of matrix in the data package using samples from the project. Any laboratory abbreviations or notations presented in the raw data or summary information will be explained or referenced in the case narrative. Final spiking concentrations will be presented in summary form. Standard tracing information will be provided. Cooler temperatures will be provided in the data packages. Run logs will be provided in the data packages.	Not applicable	Provide missing or additional deliverables for validation purposes.
Method and QAPP Requirements	The laboratory will perform the method as presented in this QAPP and will adhere to the QAPP requirements presented herein. Otherwise the laboratory will specifically note any procedures that differ from the method or the QAPP in the data package case narrative.	Not applicable	Not applicable

Table 3-19. Ignitability using USEPA Method 1010A, corrosivity using USEPA Method 9040C/9045D, total sulfide using USEPA Method 9030B/9034 and paint filter using USEPA Method 9095B quality control requirements and corrective actions

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Sample preservation	Samples must be preserved based on method and QAPP requirements	For aqueous and soil samples: cooler temperature 4°C. See Table 1 for sample preservation information.	Notify Project Manager since re-sampling may be required. Document corrective action in the case narrative.
Holding times (Sensitivity)	Samples must be prepared and analyzed within holding time.	Ignitability, corrosivity, total sulfide: Analyze 2 days from collection. Paint Filter- Analyze 28 days from collection.	1. If holding times are exceeded for initial or any reanalysis required due to QC excursions, notify the QAO since re-sampling may be required. 2. Document corrective action in the case narrative.
Initial Calibration **(Accuracy)**	Three to five point calibration standards prior to sample analysis. One standard must be at the QL concentration.	1. Linear calibration using response factor with RSD less than or equal to 10%. If RSD <10% the average calibration factor (external calibration) is used for quantitation. 2. For compounds with RSD greater than 10% use linear calibration that does not pass through the origin with least squares regression (r for un-weighted least squares regression, Coefficient of Determination or r^2 must be greater than 0.990) or non-linear calibration using no more than third order with seven standards, (COD or r^2 must be greater than 0.990).	1. Reanalyze. 2. If criteria are still not met, identify and correct problem, recalibrate. 3. Document corrective action in the case narrative - samples cannot be analyzed until calibration control limit criteria have been met.
Initial Calibration and Calibration Verification **(ICV, CCV)** **(Accuracy)**	ICV analyzed following calibration and CCV after every 10 samples and at the end of the sequence.	ICV, CCV recovery must be within 90-110% of the true value.	1. Reanalyze. 2. If criteria are still not met, identify and correct problem, recalibrate. 3. Document corrective action in the case narrative - samples cannot be analyzed until calibration control limit criteria have been met.

Table 3-19. Ignitability using USEPA Method 1010A, corrosivity using USEPA Method 9040C/9045D, total sulfide using USEPA Method 9030B/9034 and paint filter using USEPA Method 9095B quality control requirements and corrective actions

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Initial and Continuing Calibration Blank (ICB/CCB) (Sensitivity)	After ICV/CCV at beginning and end of run and at a rate of 10% or every 2 hours during run.	The absolute value of the ICB and CCB must not exceed the QL.	1. Identify and correct problem. 2. If criteria are still not met, recalibrate and reanalyze affected samples. 3. Document corrective action in the case narrative - samples cannot be analyzed until blank control limit criteria have been met.
Preparation Blank Analysis (Sensitivity)	1 per batch of samples prepared or 1 in 20, whichever is greater.	The absolute value of the method blank must not exceed the QL. Preparation blank for turbidity and color interference check is subtracted for phosphate analysis.	1. Reanalyze blank. 2. If limits are still exceeded, re-prepare and reanalyze affected samples. 3. Document corrective action in the case narrative - samples cannot be analyzed until blank criteria are met.
Laboratory Control Sample Analysis (Accuracy)	Every 20 samples or each preparation batch. Prepared independently from calibration standards.	Recovery within laboratory control limits. The lowest acceptable control limits for recovery will be 10%.	1. Reanalyze LCS and examine results of other QC analyses. 2. If recovery is still outside limits, and other QC criteria are met, report both runs. 3. If other QC criteria have not been met, stop analysis, locate and correct problem, reanalyze samples since last satisfactory LCS. 4. Document corrective action in the case narrative.
Matrix Spike Analysis (Accuracy)	Collected one per 20 samples or one per matrix (for less than 20 samples) Samples from the investigation must be used for MS/MSD or MS/Duplicate analysis.	Recovery within laboratory control limits or 75-125%. Recovery does not apply if sample concentration > 4 X spike concentration. Spike must contain all analytes. The lowest acceptable laboratory control limits for recovery will be 10%.	1. If LCS criteria are met, document in the case narrative. 2. If LCS criteria are not met, examine other QC data to identify the source of the problem. 3. Re-prepare/ reanalyze samples associated with the matrix spike and LCS. 4. Document corrective action.

Table 3-19. Ignitability using USEPA Method 1010A, corrosivity using USEPA Method 9040C/9045D, total sulfide using USEPA Method 9030B/9034 and paint filter using USEPA Method 9095B quality control requirements and corrective actions

Audit (DQI) (where applicable)	Frequency	Control Limits	Corrective Action
Laboratory Duplicate or Matrix Spike Duplicate Analysis (Precision)	Collected one per 20 samples or one per matrix (for less than 20 samples) Samples from the investigation must be used for Laboratory Duplicate and MSD analysis	RPD within laboratory control limits or 20% for RPD shall be used for original and duplicate sample values greater than or equal to five times the QL. A control limit of the QL value shall be used if either the sample or duplicate value is less than five times the CRQL.	Investigate problem 2. Document corrective action.
Field/Equipment Blank Analysis (Sensitivity)	Collected one per sampling event, or one per 20 samples or one per matrix (for less than 20 samples)	Less than QL	1. Investigate problem. 2. Document in the case narrative.
Field Duplicate Analysis (Precision)	Collected 1 per matrix; every 20 samples of similar matrix. The field duplicate identification will not be provided to the laboratory.	Validation criteria: 50% RPD for waters. For sample results that are less than or equal to five times the QL, the criterion of plus or minus two times the QL will be applied to evaluate field duplicates.	No corrective action required of the laboratory since the laboratory will not know the identity of the field duplicate samples. If these criteria are not met, sample results will be evaluated on a case-by-case basis.
Sample Batching	The laboratory will batch project samples together along with QC samples specified from the project. Non-project information will not be included in the data packages.	Not applicable	Not applicable
Dilutions	1. Dilute and reanalyze samples with concentrations that are greater than the linear range of the instrument. 2. The laboratory will note in the data package which analytical runs were used to report the sample results.	Not applicable	Not applicable. .
Laboratory control limits	Generated with results for an analyte from a minimum of 20 sample analyses. The average of the sample results and the standard deviation are calculated. The internal warning limits are established at 2 times the standard deviation and the control limits are established at 3 times the standard deviation. The control limits are updated annually.	Not applicable	Not applicable

CT Laboratories Terms and Conditions

Where a purchaser (Client) places an order for laboratory, consulting or sampling services from CT Laboratories (CTL), CTL shall provide the ordered services pursuant to these Terms and Conditions, and the related Quotation, or as agreed in a negotiated contract. In the absence of a written agreement to the contrary, the Order constitutes an acceptance by the Client of CTL's offer to do business under these Terms and Conditions, and an agreement to be bound by these Terms and Conditions. No contrary or additional terms and conditions expressed in a Client's document shall be deemed to become a part of the contract created upon acceptance of these Terms and Conditions, unless accepted by CTL in advance of the start of the project and in writing.

1. ORDERS AND RECEIPT OF SAMPLES (Sample Acceptance Policy)

1.1 The Client may place the Order (i.e., specify a Scope of Work) either by submitting a purchase order to CTL in writing, by telephone (confirmed in writing) or by negotiated contract. Whichever option the Client selects for placing the Order, the Order shall not be valid unless it contains sufficient specification to enable CTL to carry out the Client's requirements. It is the policy of CT Laboratories that samples not meeting the acceptance criteria, outlined in the NELAC standards and Section 5.8.3.2 of the DOD QSM, will not be accepted by the laboratory or will be qualified on the final report. All samples submitted to the laboratory must: (1) be accompanied by proper, full and complete documentation, including sample identification, location, date and time of collection, the collector's name, type of preservation (if any), type of sample, any special comments concerning the sample and any additional pertinent fields on the chain-of-custody. In the absence of any of the required information, the laboratory will attempt to contact the client to obtain the information; if unable to obtain the necessary information, the final report will be qualified. (2) be labeled appropriately with a unique sample identification written with indelible ink on water resistant labels. If the laboratory cannot determine the identity of a sample, it will be rejected and the client will be contacted for further instructions or resampling. (3) be in an appropriate sample container. If the container is inappropriate, the client will be contacted for further instructions or resampling. If analysis is possible, the final report will be qualified. CT Laboratories can provide a sampling guide containing approved containers and preservations for analytical methods requested. (4) adhere to specified holding times. If samples are received with less than ½ the holding time remaining for the requested test, CT Laboratories will make its best effort to analyze the samples and notify the client. If holding times are exceeded, the final report will be qualified. (5) contain adequate sample volume to perform the necessary testing. If sufficient volume is not present, the sample will be rejected and the client will be contacted for further instructions or resampling. If samples show signs of damage, contamination or inadequate preservation, the client will be notified. If analysis can be performed, the final report will be qualified. If not, the samples will be rejected and the client notified for further instructions or resampling.

1.2 CT Laboratories must be supplied with complete written disclosure of the known or suspected presence of any hazardous substances, as defined by applicable federal or state law. Where any samples which were not accompanied by the required disclosure, cause interruptions in the lab's ability to process work due to contamination of instruments or work areas, the Client will be responsible for the costs of clean up and recovery.

1.3 Prior to Sample Acceptance, the entire risk of loss or damage to samples remains with the Client. In no event will CTL have any responsibility or liability for the action or inaction of any carrier shipping or delivering any sample to or from CTL's premises. Client is responsible to assure that any sample containing any hazardous substance which is to be delivered to CTL's premises will be packaged, labeled, transported and delivered properly and in accordance with applicable laws.

2. PAYMENT TERMS

2.1 Services performed by CTL will be in accordance with prices quoted and later confirmed in writing or as stated in the Price Schedule. Invoices may be submitted to Client upon completion of any sample delivery group. Payment in advance is required for all Clients except those whose credit has been established with CTL. For Clients with approved credit, payment terms are net 30 days from the date of invoice by CTL. All overdue payments are subject to an additional interest and service charge of one and one-half percent (1.5%) (or the maximum rate permissible by law, whichever is lesser) per month or portion thereof from the due date until the date of payment. All fees are charged or billed directly to the Client. The billing of a third party will not be accepted without a statement, signed by the third party that acknowledges and accepts payment responsibility. CTL may suspend work and withhold delivery of data under this order at any time in the event Client fails to make timely payment of its invoices. Client shall be responsible for all costs and expenses of collection including reasonable attorney's fees. CTL reserves the right to refuse to proceed with work at any time based upon an unfavorable Client credit report.

3. CHANGE ORDERS, TERMINATION

3.1 Changes to the Scope of Work, price, or result delivery date may be initiated by CTL after Sample Acceptance due to any condition which conflicts with analytical, QA or other protocols warranted in these Terms and Conditions. CTL will not proceed with such changes until an agreement with the Client is reached on the amount of any cost, schedule change or technical change to the Scope of Work, and such agreement is documented in writing.

3.2 Changes to the Scope of Work, including but not limited to increasing or decreasing the work, changing test and analysis specification or acceleration in the performance of the work may be initiated by the Client after sample acceptance. Such a change will be documented in writing and may result in a change in cost and turnaround time commitment. CTL's acceptance of such changes is contingent upon technical feasibility and operational capacity.

3.3 Suspension or termination of all or any part of the work may be initiated by the Client. CTL will be compensated consistent with Section 2 of these Terms and Conditions. CTL will complete all work in progress and be paid in full for all work completed.

4. WARRANTIES AND LIABILITY

4.1 Where applicable, CTL will use analytical methodologies which are in substantial conformity with published test methods. CTL has implemented these methods in its Laboratory Quality Manuals and referenced Standard Operating Procedures and where the nature or composition of the sample requires it, CTL reserves the right to deviate from these methodologies as necessary or appropriate, based on the reasonable judgment of CTL, which deviations, if any, will be made on a basis consistent with recognized standards of the industry and/or CTL's Laboratory Quality Manuals. Client may request that CTL perform according to a mutually agreed Quality Assurance Project Plan (QAPP). In the event that samples arrive prior to agreement on a QAPP, CTL will proceed with analyses under its standard Quality Manuals then in effect, and CTL will not be responsible for any resampling or other charges if work must be repeated to comply with a subsequently finalized QAPP.

4.2 CTL shall start preparation and/or analysis within holding times provided that Sample Acceptance occurs within 48 hours of sampling or 1/2 of the holding time for the test, whichever is less. Where resolution of inconsistencies leading to Sample Acceptance does not occur within this period, CTL will use its best efforts to meet holding times and will proceed with the work provided that, in CTL's judgment, the chain-of-custody or definition of the Scope of Work provide sufficient guidance. Reanalysis of samples to comply with CTL's Quality Manuals will be deemed to have met holding times provided the initial analysis was performed within the applicable holding time. Where reanalysis demonstrates that sample matrix interference is the cause of failure to meet any Quality Manual requirements, the warranty will be deemed to have been met.

4.3 CTL warrants that it possesses and maintains all licenses and certifications which are required to perform services under these Terms and Conditions provided that such requirements are specified in writing to CTL prior to Sample Acceptance. CTL will notify the Client in writing of any decertification or revocation of any license, or notice of either, which affects work in progress.

4.4 The warranty obligations set forth in Sections 4.1, 4.2 and 4.3 are the sole and exclusive warranties given by CTL in connection with any services performed by CTL or any Results generated from such services, and CTL gives and makes NO OTHER REPRESENTATION OR WARRANTY OF ANY KIND, EXPRESS OR IMPLIED. No representative of CTL is authorized to give or make any other representation or warranty or modify this warranty in any way.

4.5 Client's sole and exclusive remedy for the breach of warranty in connection with any services performed by CTL, will be limited to repeating any services performed, contingent on the Client's providing, at the request of CTL and at the Client's expense, additional sample(s) if necessary. Any reanalysis requested by the Client generating Results consistent with the original Results will be at the Client's expense. If resampling is necessary, CTL's liability for resampling costs will be limited to actual cost or one hundred or one hundred fifty dollars ($150) per sample, whichever is less.

4.6 CTL's liability for any and all causes of action arising hereunder, whether based in contract, tort, warranty, negligence or otherwise, shall be limited to the lesser amount of compensation for the services performed or $100,000. All claims, including those for negligence, shall be deemed waived unless suit thereon is filed within one year after CTL's completion of the services. Under no circumstances, whether arising in contract, tort (including negligence), or otherwise, shall CTL be responsible for loss of use, loss of profits, or for any special, indirect, incidental or consequential damages occasioned by the services performed or by application or use of the reports prepared.

4.7 In no event shall CTL have any responsibility or liability to the Client for any failure or delay in performance by CTL which results, directly or indirectly, in whole or in part, from any cause or circumstance beyond the reasonable control of CTL. Such causes and circumstances shall include, but not be limited to, acts of God, acts of Client, acts or orders of any governmental authority, strikes or other labor disputes, natural disasters, accidents, wars, civil disturbances, equipment breakdown, matrix interference or unknown highly contaminated samples that impact instrument operation, unavailability of supplies from usual suppliers, difficulties or delays in transportation, mail or delivery services, or any other cause beyond CTL's reasonable control.

5. RESULTS, WORK PRODUCT

5.1 Data or information provided to CTL or generated by services performed under this agreement shall only become the property of the Client upon receipt in full by CTL of payment for the whole Order. Ownership of any analytical method, QA/QC protocols, software programs or equipment developed by CTL for performance of work will be retained by CTL, and Client shall not disclose such information to any third party.

5.2 Data and sample materials provided by Client or at Client's request, and the result obtained by CTL shall be held in confidence (unless such information is generally available to the public or is in the public domain or Client has failed to pay CTL for all services rendered or is otherwise in breach of these Terms and Conditions), subject to any disclosure required by law or legal process.

5.3 Should the Results delivered by CTL be used by the Client or Client's client, even though subsequently determined not to meet the warranties described in these Terms and Conditions, then the compensation will be adjusted based upon mutual agreement. In no case shall the Client unreasonably withhold CTL's right to independently defend its data.

5.4 CTL reserves the right to subcontract services ordered by the Client to another laboratory or laboratories, if, in CTL's sole judgment, it is reasonably necessary, appropriate or advisable to do so, and with the Client's permission. CTL will in no way be liable for any subcontracted services and all applicable warranties, guarantees and insurance are those of the subcontracted laboratory.

5.5 CTL shall dispose of the Client's samples 30 days after the analytical report is issued, unless instructed to store them for an alternate period of time or to return such samples to the Client, in a manner consistent with U.S. Environmental Protection Agency regulations or other applicable Federal, state or local requirements. Any samples for projects that are canceled or not accepted, or for which return was requested, will be returned to the Client at their own expense. CTL reserves the right to return to the Client any sample or unused portion of a sample that is not within CTL's permitted capability or the capabilities of CTL's designated waste disposal vendor(s).

5.6 Unless a different time period is agreed to in any order under these Terms and Conditions, CTL agrees to retain all records for five (5) years.

5.7 In the event that CTL is required to respond to legal process related to services for Client, Client agrees to reimburse CTL for hourly charges for personnel involved in the response and attorney fees reasonably incurred in obtaining advice concerning the response, preparation to testify, and appearances related to the legal process, travel and all reasonable expenses associated with the litigation.

6. INSURANCE

6.1 CTL shall maintain in force during the performance of services under these Terms and Conditions, Workers' Compensation and Employer's Liability Insurance in accordance with the laws of the states having jurisdiction over CTL's employees who are engaged in the performance of the work. CTL shall also maintain during such period, Comprehensive General and Contractual Liability (limit of $2,000,000 per occurrence/ aggregate), Comprehensive Automobile Liability, owned and hired, ($1,000,000 combined single limit), and Professional/Pollution Liability Insurance (limit of $5,000,000 per occurrence/aggregate). Any Client required changes to these limits or conditions may result in a change in cost to the Client.

7. AUDIT

7.1 Upon prior notice to CTL, the Client may audit and inspect CTL's records and accounts covering reimbursable costs related to work done for the Client, for a period of one (1) year after completion of the work. The purpose of any such audit shall be only for verification of such costs, and CTL shall not be required to provide access to cost records where prices are expressed as fixed fees or published unit prices

Instructions for completing Chain of Custody (COC)

1. **Section A and B:** Complete all Client information at top of sheet: company name, address, phone, fax, contact (the person to contact if there are questions, and who will receive the final report.), e-mail address (if available), PO#, Project Name and/or Project Number as you would like to see it appear on the report.

2. **Section C:** Invoice Information: Billing information is included in this section. This information should include the name and address of the person receiving the invoice.

3. Quote Reference should be completed if a quotation was provided by Pace Analytical. The Project Manager, and Profile No. will be completed by Pace Analytical Services.

4. **Site Location:** A separate COC must be filled out for each day of sample collection. Record the two letter postal code for the US state in which the samples were collected.

5. **Regulatory Agency:** List the program that is guiding the work to ensure proper regulations are followed.

6. **Section D:** Complete a Sample Description in the "SAMPLE ID' section as you would like it to appear on the laboratory report. The following information should also be included: the sample matrix, sample type (G (grab) or C (composite). When collecting a composite, the start time and end time should be documented in the respective boxes. The collection time for a grab (G) sample should be entered in the boxes marked 'Composite End/Grab'), Sample temp at collection (if required by state), the total number of containers, and preservative used.

7. Mark if the sample was filtered in the field by marking Y or N in 'Filtered' row by the Analysis requested.

8. Requested Analysis: List the required analysis and methods on the lines provided and place a check in the column for the samples requiring the analysis. Additional comments should be referenced in the bottom left hand corner or include attachments for extended lists of parameters.

9. The sampler should print their name in the space provided and sign their name followed by the date of the sampling event at the bottom of the COC in the spaces designated for 'SAMPLER NAME AND SIGNATURE'.

10. When relinquishing custody of the samples to a representative of the laboratory or other organization, indicate the Item Numbers of those samples being transferred; sign relinquished by, date and time, and include your affiliation.

***Important Note:**

Standard Turnaround Time is 2 Weeks/10 business days. Results will be delivered by end of business on the date due unless other arrangements have been made with your project manager.

Special Project Requirements such as Low Level Detection Limits or level of QC reported must be included on the chain of custody in the Additional Comments section.

APPENDIX A
LABORATORY CERTIFICATIONS

STATE OF LOUISIANA
DEPARTMENT OF ENVIRONMENTAL QUALITY

Is hereby granting a Louisiana Environmental Laboratory Accreditation to

CT Laboratories LLC
1230 Lange Court
Baraboo, Wisconsin 53913

Agency Interest No. 115843
Activity No. ACC20170002

According to the Louisiana Administrative Code, Title 33, Part I, Subpart 3, LABORATORY ACCREDITATION, the State of Louisiana formally recognizes that this laboratory is technically competent to perform the environmental analyses listed on the scope of accreditation detailed in the attachment.

The laboratory agrees to perform all analyses listed on this scope of accreditation according to the Part I, Subpart 3 requirements and agrees to adapt to any changes in the requirements. It also acknowledges that continued accreditation is dependent on successful ongoing compliance with the applicable requirements of Part I and the 2009 TNI Standard by which the laboratory was assessed. Please contact the Department of Environmental Quality, Louisiana Environmental Laboratory Accreditation Program (LELAP) to verify the laboratory's scope of accreditation and accreditation status.

Accreditation by the State of Louisiana is not an endorsement or a guarantee of validity of the data generated by the laboratory. To be accredited initially and maintain accreditation, the laboratory agrees to participate in two single-blind, single-concentration PT studies, where available, per year for each field of testing for which it seeks accreditation or maintains accreditation as required in LAC 33:I.4711.

State of New Jersey
Department of Environmental Protection
Certifies That

EUROFINS FRONTIER GLOBAL SCIENCES

Laboratory Certification ID # WA014
is hereby approved as a
Nationally Accredited Environmental Laboratory
to perform the analyses as indicated on the Annual Certified Parameter List
which must accompany this certificate to be valid

having duly met the requirements of the
Regulations Governing the Certification of
Laboratories and Environmental Measurements N.J.A.C. 7:18 et. seq.
and
having been found compliant with the 2009 TNI Standard approved by the
The NELAC Institute

Expires June 30, 2018

NELAP RECOGNIZED TNI ACCREDITATION BODY

Michele M. Potter
Manager

THE GREAT SEAL OF THE STATE OF NEW JERSEY

NJDEP is a NELAP Recognized Accreditation Body

This certificate is to be conspicuously displayed at the laboratory with the annual certified parameter list in a location on the premises visible to the public. Consumers are urged to verify the laboratory's current accreditation status with the State of NJ, NELAP.

New Jersey Department of Environment Protection
Environmental Laboratory Certification Program

Category: AE04 --Organics Analysis

Status	Eligible to Report NJ Data	Code	Parameter	Technique	Aproved Methods	Primary State
Certified	Yes	AE04.03580	Allyl chloride	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03600	Benzene	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03610	Benzyl chloride	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03640	Bromodichloromethane	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03650	Bromoform	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03660	Bromomethane	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03670	Butadiene (1,3-)	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03690	Butylbenzene (n-)	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03700	Carbon disulfide	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03720	Carbon tetrachloride	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03750	Chlorobenzene	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03760	Chloroethane	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03770	Chloroform	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03780	Chloromethane	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03800	Chlorotoluene (2-)	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03820	Cyclohexane	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03840	Dibromo-3-chloropropane (1,2-)	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03850	Dibromochloromethane	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03860	Dibromoethane (1,2-) (EDB)	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03870	Dichlorobenzene (1,2-)	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03880	Dichlorobenzene (1,3-)	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03890	Dichlorobenzene (1,4-)	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03900	Dichlorodifluoromethane	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03910	Dichloroethane (1,1-)	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03920	Dichloroethane (1,2-)	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03930	Dichloroethene (1,1-)	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03940	Dichloroethene (cis-1,2-)	GC/MS, Canisters	EPA TO-15	LA
Certified	Yes	AE04.03950	Dichloroethene (trans-1,2-)	GC/MS, Canisters	EPA TO-15	LA

Environmental Laboratory Certification Program

Annual Certified Parameter List and Current Status

Effective as of 12/06/2017 until 6/30/2018

Laboratory Name: EUROFINS LANCASTER LABS ENVIRONMENTAL Laboratory Number: PA011 Activity ID: NLC 170004
2425 NEW HOLLAND PK
LANCASTER PA 176015994

Category: NPW11--Organic Parameters - Chromatography/MS

Status	Eligible to Report NJ Data	Code	Parameter	Technique	Aproved Methods	Primary State
Certified	Yes	NPW11.04480	Octachlorobiphenyl (2,2',3,3',4,5', 6,6'-) (PCB 201)	Extraction, SIM, GC/MS	EPA 1668A	PA
Certified	Yes	NPW11.04490	Octachlorobiphenyl (2,2',3,3',5,5', 6,6'-) (PCB 202)	Extraction, SIM, GC/MS	EPA 1668A	PA
Certified	Yes	NPW11.04500	Octachlorobiphenyl (2,2',3,4,4',5,5', 6-) (PCB 203)	Extraction, SIM, GC/MS	EPA 1668A	PA
Certified	Yes	NPW11.04510	Octachlorobiphenyl (2,2',3,4,4', 5,6,6'-) (PCB 204)	Extraction, SIM, GC/MS	EPA 1668A	PA
Certified	Yes	NPW11.04520	Octachlorobiphenyl (2,3,3',4,4',5,5', 6-) (PCB 205)	Extraction, SIM, GC/MS	EPA 1668A	PA
Certified	Yes	NPW11.04530	Nonachlorobiphenyl (2,2',3,3',4,4', 5,5',6-) (PCB 206)	Extraction, SIM, GC/MS	EPA 1668A	PA
Certified	Yes	NPW11.04540	Nonachlorobiphenyl (2,2',3,3',4,4', 5,6,6'-) (PCB 207)	Extraction, SIM, GC/MS	EPA 1668A	PA
Certified	Yes	NPW11.04550	Nonachlorobiphenyl (2,2',3,3',4,5,5', 6,6'-) (PCB 208)	Extraction, SIM, GC/MS	EPA 1668A	PA
Certified	Yes	NPW11.04560	Decachlorobiphenyl (PCB 209)	Extraction, SIM, GC/MS	EPA 1668A	PA
Certified	Yes	NPW11.07870	Acetone	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.07880	Acetonitrile	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.07890	Acrolein	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.07900	Acrylonitrile	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.07910	Allyl chloride	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.07940	Benzene	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.07950	Bromobenzene	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.07960	Bromochloromethane	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.07970	Bromodichloromethane	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.07990	Bromoform	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08000	Bromomethane	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08030	Butanone (2-) [Methyl ethyl ketone]	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08040	Butyl acetate (n-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08070	Butylbenzene (n-)	GC/MS, P & T, Capillary Column	EPA 624	PA

Status	Eligible to Report NJ Data	Code	Parameter	Technique	Aproved Methods	Primary State
Certified	Yes	NPW11.08080	Carbon disulfide	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08090	Carbon tetrachloride	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08100	Chlorobenzene	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08110	Chloroethane	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08120	Chloroethyl vinyl ether (2-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08130	Chloroform	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08140	Chloromethane	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08150	Chlorotoluene (2-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08160	Chlorotoluene (4-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08180	Cyclohexane	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08200	Dibromo-3-chloropropane (1,2-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08210	Dibromochloromethane	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08220	Dibromoethane (1,2-) (EDB)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08230	Dibromomethane	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08260	Dichlorobenzene (1,2-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08270	Dichlorobenzene (1,3-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08280	Dichlorobenzene (1,4-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08290	Dichloroethane (1,1-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08300	Dichloroethane (1,2-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08310	Dichloroethene (1,1-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08320	Dichloroethene (cis-1,2-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08330	Dichloroethene (trans-1,2-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08340	Dichloropropane (1,2-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08350	Dichloropropane (1,3-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08360	Dichloropropane (2,2-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08370	Dichloropropene (1,1-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08380	Dichloropropene (cis-1,3-)	GC/MS, P & T, Capillary Column	EPA 624	PA
Certified	Yes	NPW11.08390	Dichloropropene (trans-1,3-)	GC/MS, P & T, Capillary Column	EPA 624	PA

Re: Annual Scope of Accreditation

Dear Mr. Letterer:

The Louisiana Department of Environmental Quality's laboratory accreditation program, in accordance with Louisiana Administrative Code, Title 33, Part I, Subpart 3, Laboratory Accreditation, accredits this laboratory for Fiscal Year 2018. This accreditation does not constitute an endorsement of the suitability of the listed methods for any specific purpose. The laboratory is accredited for the method as identified on the application for accreditation; if the method is partially identified on the application for accreditation, the laboratory is accredited for the versions listed on the current application or referenced in the laboratory standard operating procedure.

National Environmental Laboratory Accreditation Program (NELAP) accreditation is granted **only** for those methods/analytes for which "NELAP" is indicated as the type of accreditation. "STATE" is indicated as the type of accreditation for those methods/analytes for which accreditation by the Louisiana Environmental Laboratory Accreditation Program (LELAP) is granted. Accreditation is dependent on the laboratory's successful ongoing compliance with regulations as outlined in the Louisiana Administrative Code, Title 33, Part I, Subpart 3, Laboratory Accreditation, and with the standards adopted by the NELAP Accreditation Council.

The accreditation certificate is the property of the State of Louisiana. Should your accreditation be suspended or revoked, your laboratory must return the certificate of accreditation to the department and delete any electronic copies until your accreditation status is restored.

LAC 33:I.5313.A and/or the 2009 TNI Standard require that the laboratory report include all relevant information. Therefore, the certificate number shall be placed in the upper right corner of all laboratory reports. If the test report includes results of any test for which the laboratory is not accredited, the unaccredited results must be clearly identified as such.

We request that you examine the scope of accreditation attachment for accuracy and completeness. If you find that an analyte for which you expected to be accredited is not listed, please examine your records to ensure that:

1. You have met the requirements for successful participation in proficiency test studies as outlined in LAC 33:I.4711 and in the 2009 TNI Standard.

2. In the case of accreditation by recognition, the requested analyte must be listed for the requested method and matrix on both the certificate issued by the Primary Accreditation Body ***and*** on the Louisiana application form.

If after reviewing this information, the scope and/or certificate are inaccurate, please notify us immediately.

If you have any questions, please contact your assigned assessor Grant Aucoin, Environmental Scientist at (225) 219-3301.

Sincerely,

Cheryl Sonnier Nolan
Administrator
Public Participation and Permit Support Services Division

STATE OF LOUISIANA
DEPARTMENT OF ENVIRONMENTAL QUALITY

Is hereby granting a Louisiana Environmental Laboratory Accreditation to

Pace Analytical Services LLC - Mobile Lab Services
2525 Advance Rd
Madison, Wisconsin 53718-6774

Agency Interest No. 152019
Activity No. ACC20170003

According to the Louisiana Administrative Code, Title 33, Part I, Subpart 3, LABORATORY ACCREDITATION, the State of Louisiana formally recognizes that this laboratory is technically competent to perform the environmental analyses listed on the scope of accreditation detailed in the attachment.

The laboratory agrees to perform all analyses listed on this scope of accreditation according to the Part I, Subpart 3 requirements and agrees to adapt to any changes in the requirements. It also acknowledges that continued accreditation is dependent on successful ongoing compliance with the applicable requirements of Part I and the 2009 TNI Standard by which the laboratory was assessed. Please contact the Department of Environmental Quality, Louisiana Environmental Laboratory Accreditation Program (LELAP) to verify the laboratory's scope of accreditation and accreditation status.

Accreditation by the State of Louisiana is not an endorsement or a guarantee of validity of the data generated by the laboratory. To be accredited initially and maintain accreditation, the laboratory agrees to participate in two single-blind, single-concentration PT studies, where available, per year for each field of testing for which it seeks accreditation or maintains accreditation as required in LAC 33:I.4711.

CATHERINE R. McCABE
Commissioner

June 3, 2019

Dear Laboratory Manager:

Your fiscal year 2020 (FY20) laboratory certification renewal application has been processed and a Certificate and Annual Certified Parameter List (ACPL) that reflects the current status of your facility are enclosed. If there are any discrepancies, please contact your Laboratory Certification Officer to verify information and make arrangements for a new ACPL. If the Office of Quality Assurance does not receive documentation of any discrepancies before July 10, 2019 this ACPL will be considered final and any changes received thereafter will be treated as a modification application. Effective with the receipt of this letter, your facility's certification status is valid through June 30, 2020. Both the ACPL and Certificate must be conspicuously displayed at your facility in a location on the premises that is visible to the public.

As always, we are available to discuss any comments or questions. Please do not hesitate to contact your laboratory certification officer or me.

Sincerely,

Michele M. Potter
Manager

Enclosures: ACPL; Certificate

RE:	Phase II Remedial Investigations		
FILE:	2420/46425		
DATE:	October 4, 2013		

INTRODUCTION

This memorandum has been prepared to document planned Phase II Remedial Investigations (RI) at Hercules Incorporated's (Hercules) Former Kenvil Works facility in Kenvil, New Jersey (the Site). These investigations will be conducted to delineate the extent of constituents detected a concentrations exceeding the applicable remediation standards in the various media present at the Site. This memorandum has been prepared in accordance with the scope of work detailed in Hercules's March 26, 2010 Request for bid and subsequent meetings between Hercules and O'Brien & Gere. O'Brien & Gere assumes the scope of work detailed below, the planned investigation methods, and subsequent reports will be reviewed by Hercules' Licensed Site Remediation Professional (LSRP).

The additional RI planned for Site will include the following:

- Groundwater Sampling
- Monitoring Well Installation
- Surface Water Sampling
- Sediment Sampling
- Soil Screening for Dioxins at Former Burning Grounds
- Down-Gradient (off-Site) Delineation of the TNT Area Groundwater Plume Using Waterloo Sampling Techniques
- Soil Sampling to Delineate the Extent of Constituents at Concentrations above applicable Standards

The remedial investigations will be conducted in accordance with the procedures detailed in the following New Jersey Department of Protection (NJDEP) approved documents prepared by MWH Americas, Inc. (MWH) on behalf of Hercules:

- 2005 Revised Field Quality Assurance Project Plan (FQAPP)
- 2006 Revised Site-Wide Remedial Investigation Work Plan (RIWP)

Additionally, laboratory analysis and sample handling will be conducted in accordance with 2013 *Quality Assurance Project Plan* (QAPP) prepared by O'Brien & Gere.

Sample locations were selected based on the data provided in the following reports and correspondence:

- Remedial Investigation Report Volume A - Summary (May 2007) by MWH
- Remedial Investigation Report Volume B - Soil - Text, Figures, Tables and Appendices (April 2007) by MWH
- Remedial Investigation Report Volume C - Groundwater - Text, Figures, Tables and Appendices (February 2007) by MWH
- Remedial Investigation Report Volume D - Sediment - Text, Figures, Tables and Appendices (December 2006) by MWH
- Remedial Investigation Report Volume E - Surfacewater - Text, Figures, Tables and Appendices (March 2007) by MWH
- Additional Groundwater Remedial Investigation Sampling Report (June 2009) by Environmental Alliance (EA)
- November 18, 2010 Letter from the NJDEP

PDF versions of these documents are provided on CD in Attachment 1

The following tables and figures detailing sampling locations and required laboratory analysis are provided:

Tables

Table 1 – Groundwater Screening Plan for E&E Compounds
Table 2 – Proposed Monitoring Well Construction Details
Table 3 - Surfacewater Sampling Plan
Table 4 - Sediment Sampling Plan
Table 5 – Groundwater Sampling Plan
Table 6 - Burning Grounds Soil Screening Plan
Table 7 – Off-Site TNT Groundwater Sampling Plan
Table 8 – Soil Sampling Plan

Figures

Figure 1 - Site Plan Showing Monitoring Well Locations
Figure 2 - Site Plan Showing Surface Water Sample Locations
Figure 3 - Site Plan Showing Sediment Sample Locations
Figure 4 - Site Plan Showing Burning Grounds Soil Boring Locations
Figure 5 - Off-Site TNT Groundwater Sampling Locations

Additional information provided in this memorandum include:

- Project organization/contact
- Procedures for equipment decontamination
- Sample handling and field custody procedures
- Field logbook procedures

PROJECT ORGANIZATION/CONTACT INFORMATION

O'Brien & Gere will be responsible for project management, sample collection, data reduction and reporting. LSRP services will be provided by WSP Environment & Energy. The LSRP will oversee and approve the development of work plan related documents and the Remedial Investigation Report. Responsibilities for key project team members are summarized below.

Regulatory Agency and Client Key Personnel

An independent LSRP, contracted by Hercules, has oversight authority on behalf of Hercules for corresponding with NJDEP.

The LSRP contact information is as follows:

Mark Foley -LSRP
Senior Project Director
WSP Environment & Energy
200 Cottontail Lane, Suite A112W
Somerset, NJ 08873
mark.foley@wspgroup.com
(732) 564-0888 ext. 16 - Office

Hercules Representative

Mr. Edward Meeks is the primary contacts at Hercules and is responsible for the execution of each phase of the project, including any correspondence and coordinating activities with NJDEP.

Hercules's contact information is as follows:

Edward Meeks - Project Manager
Remediation Project Manager
500 Hercules Road
Building 8139/130
Wilmington, DE 19808-1599
edmeeks@ashland.com
(302) 995-3433 – Office

O'Brien & Gere Key Personnel

O'Brien & Gere Project Officer

Mike Kozar, P.G. is the O'Brien & Gere Project Officer and has overall responsibility for meeting the stated project objectives. In addition, he is responsible for providing the O'Brien & Gere Project Manager with access to O'Brien & Gere corporate resources.

The O'Brien & Gere Project Officer contact information is as follows:

Michael Kozar – Vice President
O'Brien & Gere Project Officer
Bentwood Campus

301 East Germantown Pike/3rd floor
East Norriton, PA 19401
Michael.Kozar@obg.com
(484) 804-7212 – Office

O'Brien & Gere Project Manager

John Lucey, P.G. is the O'Brien & Gere Project Manager and is responsible for implementing the project and has the authority to commit the resources necessary to meet project objectives and requirements. His primary function is to meet the technical, financial, and scheduling objectives and will provide direction to O'Brien & Gere Project Team.

The O'Brien & Gere Project Manager contact information is as follows:

John Lucey –Project Associate
O'Brien & Gere Project Manager
200 Biddle Avenue
Suite 203
Newark, DE 19702
John.Lucey@obg.com
(302) 804-7212 – Office

O'Brien & Gere QA Officer

Karen Storne is the O'Brien & Gere QA Officer (QAO) for this project. She will manage and be responsible for QA/QC review of data generated during the sample collection activities. If QA problems or deficiencies requiring special action are identified, the O'Brien & Gere QAO, Project Manager, and Project Officer will determine the appropriate corrective action. The QAO will then be responsible for follow-up and oversight of corrective action implementation, to the satisfaction of Hercules and the NJDEP representative.

The O'Brien & QA Officer contact information is as follows:

Karen Storne–Technical Associate
O'Brien & Gere QA Officer
333 West Washington Street
Syracuse, NY 13202
Karen.Storne@obg.com
(315) 662-3458

O'Brien & Gere Field Investigation Manager

The O'Brien & Gere Field Investigation Manager will be responsible for directing and coordinating the day-to-day activities while field activities are underway.

O'Brien & Gere Field Sampling Personnel

O'Brien & Gere field sampling personnel will be responsible for collection, packaging, preservation, and shipping of environmental samples in accordance with the QAPP and applicable NJDEP requirements. Field sampling personnel will also collect field data and monitor Site health and safety.

Health and Safety Coordinator

Karin Robachefski, CHST, OHST is the O'Brien & Gere Health & Safety Coordinator and will be responsible for monitoring Site health and safety during the sampling events.

The O'Brien & Gere Health and Safety Coordinator contact information is as follows:

Karin Robachefski
Health & Safety Specialist
1090 King Georges Post Road
Suite 904

Laboratory Management

Eurofins Lancaster Laboratories of Lancaster, Pennsylvania will analyze samples collected during the sampling activities. The laboratory contact information is as follows:

Eurofins Lancaster Laboratories
2425 New Holland Pike
Lancaster, Pennsylvania 17601
717-656-2300

Laboratory Project Manager

Wendy Kozma is the Laboratory Project Manager for Eurofins Lancaster Laboratories and will be responsible for:

- Coordinating sample bottle delivery and sample pickups from the Site
- Supervising the in-house chain-of-custodies.
- Scheduling sample analysis.
- Overseeing data review.
- Overseeing preparation of analytical reports.

It will be the responsibility of the Lancaster Laboratory Project Manager to approve final analytical reports prior to submission to O'Brien & Gere.

Monitoring Well Installation

Drilling Services

Drilling services will be provided by Summit Drilling Co., Inc. The drilling services will include monitoring well installation, monitoring well development, soil boring installation, management of investigation derived waste, monitoring well permitting, and preparation of monitoring well Forms A.

Summit Drilling Co., Inc contact information is as follows:

David Adams
Project Manager
81 Chimney Rock Road
Bridgewater, NJ 08807
908-722-4266

Surveying Services

Surveying services will be provided by Vargo Associates. The surveying services will include surveying locations and elevations of newly installed monitoring wells, soil borings, dioxin screening locations, and Waterloo sampling locations. The surveyor will prepare monitoring well Forms B and provide the elevation and location data in electronic format (MS Excel).

Vargo Associates contact information is as follows:

Mike Vargo
Vargo Associates Surveying Manager
2771 Delsea Drive, Franklinville, NJ 08322
Franklinville, NJ 08322
(856) 694-1716

REMEDIAL INVESTIGATION ACTIVITIES

Task 1 - Groundwater E&E Screening

Groundwater sampling results from 2006 and 2008 indicated the cyclotrimethylenetrinitramine (RDX) plume has migrated approximately 500 feet in two years. To accurately locate the leading edge of the RDX plume, 16 monitoring wells (MW-15 through MW-18, MW-23, MW-25, MW-33 through MW-37, MW-41, and MW-J2 through MW-J5) will be sampled for explosive and energetic (E&E) compounds (see Table 1) prior to installing monitoring wells MW-52 and MD-52D, which are intended to monitor the downgradient edge of the RDX plume. The groundwater E&E screening activities will be conducted prior to mobilizing to the Site to for monitoring well installation.

Purging and Sampling Methods

Prior to commencing well purging and groundwater sample collection, the depth to groundwater and depth to bottom of each monitoring well in the vicinity of the RDX plume will be obtained and recorded. These measurements will be used to calculate monitoring well purge volumes and groundwater flow in the vicinity of the RDX plume. The depth to water will be measured in each well by slowly lowering a decontaminated electronic water level meter to the nearest 0.01 foot and will be recorded in the field notebook.

The monitoring wells will be purged and sampled using conventional groundwater sampling techniques. The monitoring well purging activities will be accomplished by removing three casing volumes of water with a submersible electric pump with new dedicated polyethylene discharge tubing. Pumping rates will be kept as low as is reasonably (See well sampling data forms in MHW's *RI Report Volume C*) to avoid pumping the well dry. If the well is pumped at a rate of 0.5 gallons per minute (gpm) or less and purged dry, no additional purging will be considered necessary and the well will be allowed to recover until a sufficient quantity of water is present in the well to collect the groundwater sample. Purge water will be discharged to the ground surface down gradient of the well. The field parameters pH, specific conductance, temperature, dissolved oxygen, oxidation reduction potential, and turbidity will be measured at the start of the purge, after each well volume has been removed and at the time of sampling. After each well is purged a groundwater sample will be collected with a dedicated, disposable Teflon® bailer.

Field procedures, including groundwater depth measurements (for elevation calculations and purge volume calculations), monitoring well purging and field testing of groundwater quality (including pH, specific conductance, temperature, dissolved oxygen, oxidation reduction potential, and turbidity), decontamination of purging and sampling equipment and groundwater sampling, will be conducted in accordance with the procedures detailed in the FQAPP.

Laboratory Analysis

The groundwater and associated quality control samples generated will be submitted to Eurofins Lancaster Laboratories, a New Jersey certified laboratory, for analysis. The samples will be analyzed for E&E compounds, as indicated in Table 1.

Sample bottle requirements and preservation methods are detailed in Table 1 of the QAPP.

QA/QC samples that will be collected as part of the E&E screening program will include the following:

- One duplicate sample per each 10 field samples
- One field blank per each 10 field samples
- One MS/MSD sample per sample delivery group

Task 2 - Monitoring Well Installation

O'Brien & Gere will install ten (10) additional unconsolidated monitoring wells to complete the delineation of constituents of concern (COCs) in groundwater. The monitoring wells will be used to evaluate groundwater quality along the eastern edge of B-Line, delineate the southern extent of the TNT plume at the site boundary, delineate the depth of groundwater impact in the TNT Area groundwater plume, and evaluate groundwater quality downgradient of the RDX plume. Proposed monitoring well locations are indicated on Figure 1.

The rational for the installation of each well, anticipated well depths, and selected drilling methods are provided in Table 2. The locations for monitoring wells MW-52 and MD-52D, which are intended to monitor the downgradient edge of the RDX plume, may change based on the results of the E&E groundwater screening activities described above. Monitoring well installation, development, and surveying activities are summarized below.

Preparatory Activities

A minimum of three weeks prior to the installation of the monitoring wells, the selected driller will submit monitoring permits to the NJDEP. The driller will notify New Jersey One Call of the planned drilling activities, a minimum of 72 hours prior to drilling, to obtain a utility mark out. Monitoring wells locations will be cleared by Hercules, prior to mobilization of the drill rig.

Monitoring Well Installation Activities

The monitoring wells will be installed using either hollow stem auger (shallow wells) or mud rotary (deep wells) drilling techniques. Continuous split spoon samples will be collected during the installation of the pilot boring at each monitoring well location. The split spoon samples will be screened by an O'Brien & Gere geologist using a photo ionization detector (PID). The O'Brien & Gere geologist will also describe the soil cuttings using the *Burmeister Soil Classification* System. Soil cuttings generated during the well installation process will be spread across the ground surface, in proximity to the well. Standard Operating Procedures for monitoring well installation are provided in the February 2006 FQAPP prepared by MWH.

The monitoring wells will be constructed using Schedule 40 PVC casing and 0.010-inch, slotted PVC well screen, in accordance with the specifications provided in Table 2. Screen zone length will not exceed 10 feet. Morie No. 0 gravel pack will be placed from the bottom of the boring to five feet above the top of the screen zone. The remainder of the annular space will be tremie grouted using a cement-bentonite grout. The monitoring well installations will be completed with locking, steel casings. Detailed monitoring well installation procedures are provided in Section 3.3.1 of the RIWP.

After monitoring well activities have been completed, the driller will prepare Monitoring Well Forms A for the newly installed wells.

Monitoring Well Development

The monitoring wells will be developed using pumping and surging techniques until the discharge is clear. Water quality parameters (pH, conductivity, temperature, dissolved oxygen, and turbidity) along with the discharge rate will be measured periodically during the development process and recorded in the field

notebook. Well development water will be discharged to the ground surface down gradient from the well head. Detailed monitoring well development procedures are provided in Section 3.3.2 of the RIWP.

Monitoring Well Surveying

A New Jersey licensed surveyor will establish the horizontal location and elevation of the newly installed wells. Horizontal control will be established to the nearest 0.1 ft and referenced to the New Jersey State Plane Coordinate system (NAD 83). Vertical control will be established to the nearest 0.01 ft and referenced to the NGVD 1929. The surveyor will prepare Monitoring Well Forms B for the newly surveyed wells.

Task 3 - Surface Water Sampling

The surface water sample collection program will include the collection of 25 surface water samples to evaluate surface water outside defined channels, confirm surface water quality exiting site, and to evaluate dissolved constituents present in surface water adjacent to Duck Pond. The surface water sample locations are indicated on Figure 2. Analytical parameters and rationale for the collection of the surface water samples are provided on Table 3. Surface water sampling procedures are summarized below.

Surface water samples will be collected from the Eastern, Central and Western Drainage Areas and Tributaries to Duck Pond by walking into the selected areas (downstream to upstream), as water depths in these areas are typically less than two feet. The collection of surface water samples from Duck Pond may require the use of a boat as water depths can be in excess of four feet.

Surface Water Sampling Access

Access to surface water sampling locations can be achieved by utilizing a small raft or boat (to be provided by Hercules), a temporary bridge placed over narrow stream channels, and hip waders in shallow wetland areas.

Surface Water Sampling Methods

Two types of surface water sampling will be conducted (discrete depth sampling and surface sampling). Discrete depth sampling will be conducted at one location (See Location F on Table 3 and Figure 2). Surface sampling will be conducted in shallower water bodies such as the southern wetlands. The surface water sampling procedures are summarized below.

Discrete Depth Sampling

Discrete depth samples will be collected with a weighted bottle sampler. The weighted bottle sampler consists of a glass bottle equipped with a stopper that can be remotely removed from the surface, and weights to carry the bottle to the desired sampling depth. The discrete depth surface water sampling activities will be conducted in accordance with the procedures summarized below:

- The weighted bottle sampler will be lowered to the desired sampling depth
- The stopper will be removed from the bottle to allow it to fill with water
- The stopper is replaced in the bottle
- The sampler is retrieved and the collected sample is transferred to laboratory provided sample containers

Detailed discrete depth surface water sampling procedures are provided in Section 10.1 of the FQAPP.

Shallow Surface Water Sampling

Shallow surface water samples will be collected using a dip sampler. Deeper, discrete depth, surface water samples (greater than one foot) will be collected using a weighted bottle sampler. Shallow surface water samples will be collected by slowly submerging a laboratory-provided glass sample bottle horizontally into the water at the designated sample collection point. The bottle will be gradually turned upright, keeping the lip just under the surface so that only surface water is collected. Care will be taken to minimize surface disturbance throughout the sampling process. If the water is not deep enough to turn the bottle upright, the bottle will be held at an angle as steep as possible with the lip remaining just under the surface. In the event field personnel cannot easily access the sampling point or disturbance of the sediment is expected, the glass sample collection container will be attached to a pole of sufficient length to reach the sampling point.

Detailed surface water sampling procedures are provided in Section 10.2 of the FQAPP

Co-Located Samples

When surface water and sediment samples are taken at the same locations, the surface water sample will be collected first to minimize turbidity and reduce the potential of contaminating the surface water sample with disturbed sediment. Where samples are collected at multiple depth intervals, the samples will be collected in descending order from shallowest to deepest. In addition, down-stream samples will be collected prior to up-stream samples.

Laboratory Analysis

The surface water and associated quality control samples generated will be submitted to Eurofins Lancaster Laboratories, a New Jersey certified laboratory, for analysis. The samples will be analyzed for the following parameter, as indicated in Table 3:

- Semi-volatile organic compounds (SVOCs)
- E&E Compounds
- Target Analyte List (TAL) Metals
- Hardness
- pH

Sample bottle requirements and preservation methods are detailed in Table 1 of the QAPP.

QA/QC samples that will be collected as part of the surface water sampling program will include the following:

- One duplicate sample per each 20 field samples
- One field blank per each 10 field samples but no more than one per day
- One MS/MSD sample per sample delivery group

Surface Water Sampling Point Documentation

Surface water sampling locations will be documented using GPS methodologies. After each surface water sample has been collected horizontal location will be established and referenced to the New Jersey State Plane Coordinate system (NAD 83). Horizontal coordinates will be recorded in the field book.

Task 4 - Sediment Sampling

The sediment sample collection program will include the collection of 25 sediment samples to confirm depth of constituents at concentrations above applicable standards, confirm sediment quality adjacent to site outfall, and evaluate sediment quality outside defined channels within wetland areas. The sediment samples with be collected from the streams, wetlands and ponds present at the Site. The sediment sample locations are indicated on Figure 4. Analytical parameters and rationale for the collection of the sediment samples are provided on Table 4.

Sediment samples will be collected from the Eastern, Central and Western Drainage Areas and Tributaries to Duck Pond by walking into the selected areas (downstream to upstream) as water depths in these areas are typically less than two feet. The collection of sediment samples from Duck Pond may require the use of a boat as water depths can be in excess of four feet. Sediment sampling procedures are summarized below.

Sediment Sampling Access

Access to sediment sampling locations can be achieved by utilizing a small raft or boat (to be provided by Hercules), a temporary bridge placed over narrow stream channels, and hip waders in shallow wetland areas.

Sediment Sample Collection Methods

Sediment samples will be collected using one of two sampling devices. The two sediment sampling techniques involve the soil coring device/bucket auger (cohesive/compact sediments) and the silver bullet sampler (liquefied sediments). The soil coring device/bucket auger and silver bullet sampling procedures are described below.

Soil Coring Device/Bucket Auger

Shallow sediment samples can be collected with a bucket auger, provided the sediment is sufficiently cohesive or competent to be held within the bucket auger without losing the fine grained components of the sediment. The soil bucket auger will be advanced by hand at each sampling location for classification and sample collection. The bucket auger will be advanced at 6-inch intervals and then removed from the borehole for evaluation. Sediment sample collection procedures using a bucket auger are summarized below:

- Sample intervals will be selected for analyses as specified in Table 4.
- The bucket auger will be advanced to the desired depth and removed for sediment classification and sample collection.
- The sample material collected will be placed into a decontaminated stainless steel bowl and homogenized.
- Sample material will be transferred from the stainless steel bowl to the laboratory-supplied sample containers

Detailed procedures for collecting sediment samples using a bucket auger are provided in Section 8.2.1 of the FQAPP.

Silver Bullet Sampler

The silver bullet sampler is an aluminum alloy cylinder into which a laboratory provided clean glass collection tube is inserted. The silver bullet sampler is generally utilized to collect samples of liquefied sediments. The top of the sampler is equipped with a T-handle which is used to push the sampler to the desired depth within the sediment. Once the desired sampling depth is reached, the sampler is rotated 360° counter clockwise filling the collection jar with sediment. After the silver bullet sampler is retrieved, sediment samples will be collected in the following manner:

- The contents of the silver bullet sampler will then be emptied into a decontaminated stainless steel bowl and homogenized.
- Sample material for non-VOC analysis will transferred from the stainless steel bowl to the laboratory-supplied sample containers

Detailed procedures for collecting sediment samples using a silver bullet sampler are provided in Section 8.2.2 of the FQAPP.

Co-Located Samples

When surface water and sediment samples are taken at the same locations, the surface water sample will be collected first to minimize turbidity and reduce the potential of contaminating the surface water sample with disturbed sediment. Where sediment samples are collected at multiple depth intervals, the sediment samples will be collected in descending order from shallowest to deepest. In addition, sediment samples from down-stream locations will be collected prior to those from up-stream locations.

Laboratory Analysis

The sediment and associated quality control samples generated will be submitted to Eurofins Lancaster Laboratories, a New Jersey certified laboratory, for analysis. The samples will be analyzed for the following parameter, as indicated in Table 4:

- Polynuclear aromatic hydrocarbons (PAHs)
- E&E Compounds
- TAL Metals
- Moisture
- Percent solids
- Total organic carbons (TOC)

Sample bottle requirements and preservation methods are detailed in Table 1 of the QAPP.

QA/QC samples that will be collected as part of the sediment sampling program will include the following:

- One duplicate sample per each 20 field samples
- One field blank per each 10 field samples but no more than one per day
- One MS/MSD sample per sample delivery group

E&E Screening

Prior to shipping sediment samples to the laboratory, the samples will be screened for E&E compounds. If the screening indicates E&E compounds are not present, the sediments will shipped to the laboratory. Field screening for E&E compounds will be conducted in accordance with Section 5.1 of the FQAPP. E&E field screening kits will be provided by Hercules.

Sediment Sampling Point Documentation

Sediment sampling points will be documented using GPS methodologies. After each sediment sample has been collected horizontal location will be established and referenced to the New Jersey State Plane Coordinate system (NAD 83). Horizontal coordinates will be recorded in the field book.

Task 5 - Groundwater Sampling

At least two weeks after the new monitoring wells have been developed; O'Brien & Gere will collect groundwater samples from the 10 newly-installed monitoring wells (MW-43D, MW-49, MW-49D, MW-50, MW-50D, MW-51, MW-52, MW-52D, MW-53, and MW-53D) using low-flow sampling techniques. One groundwater sample will be collected from each wetted 5-foot section of screen length (i.e., two samples per well), consistent with NJDEP policy. The samples will be analyzed for VOCs, SVOCs, TAL metals, and E&E compounds. The groundwater samples will be collected to delineate the extent of COCs in groundwater

The *Additional GW-RI Report* (June 2009) prepared by Environmental Alliance identified 17 monitoring wells with lead present in groundwater samples at concentrations exceeding the NJDEP Class IIA GWQC. The previous groundwater sampling activities at the Site only identified two monitoring wells with lead present in the samples at concentrations exceeding the Class IIA GWQC. To further evaluate lead concentrations at these locations additional groundwater samples will be collected from the following 17 monitoring wells using low-flow sampling techniques: (MW-3A , MW-5, MW-7PD, MW-10, MW-12, MW-12D, MW-16, MW-21, MW-26D, MW-34, MW-37, MW-40, MW-44, MW-44D, MW-47, MW-J1D, and MW-J2).

The analytical parameters for the groundwater samples and pump depth settings are provided on Table 5. Monitoring well locations are indicated on Figure 1. Groundwater sampling procedures are summarized below.

Well Purging Methodology

Groundwater sampling will be conducted in accordance with the low-flow sampling procedures detailed in the February FQAPP prepared by MWH, as modified below. Each well will be purged minimum of two hours to reduce turbidity. A Grundfos® 2-inch diameter adjustable speed submersible pump and new, dedicated tubing Teflon®-lined tubing will be used to purge each monitoring well prior to sampling. The pump will be lowered into the well until the pump intake is at the required sampling interval (see above tables). The wells will be pumped at a rate to prevent drawdown from exceeding 0.3 feet (less than 0.5 L/min). Discharge from the pump will be diverted to a flow-through cell with a multi-meter probe capable of measuring pH, temperature, conductivity, dissolved oxygen (DO), oxidation-reduction potential and (ORP. Turbidity will be measured using a separate meter external to the flow-through cell. Stabilization parameters are as follow:

- ± 0.1 pH units
- ± 3 percent for temperature
- ± 3 percent for conductivity
- ± 10 percent for dissolved oxygen
- ± 10 millivolts (mV) for ORP

- ± 10 percent for turbidity, with the maximum turbidity less than 40 Nephelometric Turbidity Units
- <0.3 feet of water level drawdown

If these parameters have not stabilized after two hours, the LSRP will be notified. Based on information provided by O'Brien & Gere, the LSRP will decide which of the following three options should be considered:

- Continue purging in an attempt to achieve stabilization
- Discontinue purging, do not collect samples, and document attempts to reach stabilization in the log book
- Discontinue purging, collect samples, and document attempts to reach stabilization in the log book

For wells with two sampling intervals, the sample from the upper interval will be collected first. After that sample has been collected, the pump will be lowered to second sample interval and purging will commence. Pumps will be decontaminated between wells in accordance with the procedures detailed in the FQAPP.

Laboratory Analysis

Groundwater samples for newly installed monitoring well will be analyzed for the following parameters:

- VOCs
- SVOCs
- E&E compounds
- TAL Metals

Groundwater samples to be collected from existing monitoring wells will be analyzed for total and dissolved lead. The analytical parameters for the groundwater are summarized in Table 5. Following stabilization of water-quality parameters, as described above, the discharge from the well pump will be removed from the flow-through cell. At this point, the pumping rate and depth to water will be measured to ensure that a rate increase has not occurred due to the drop in hydraulic head associated with the closed flow-through cell. If necessary, the pumping rate will be reduced to match the purge rate.

Groundwater samples will be collected in appropriate sample containers as listed in QAPP. Sample bottles will be filled from each monitoring well in the following order:

- VOCs
- SVOCs
- E&E Compounds
- TAL Metals

Sample bottle requirements and preservation methods are detailed in Table 1 of the QAPP.

QA/QC samples that will be collected as part of the groundwater sampling program will include the following:

- One trip blank sample per sample shipment that require analysis for VOCs
- One duplicate sample per each 20 field samples
- One field blank per each 10 field samples but no more than one per day
- One MS/MSD sample per sample delivery group

Task 6 - Soil Sampling At Open Burning Grounds

O'Brien & Gere will collect 20 soil samples from around four former open burning grounds present at the Site to screen for the presence of dioxins and furans. These samples were requested by the NJDEP to evaluate if dioxin and furan compounds are present around the former burning grounds. The former open burning ground soil sample locations are indicated on Figure 4. Sampling depth and analytical methods are provided on Table 6. Soil sampling procedures are summarized below.

Soil Sampling

An O'Brien & Gere geologist will collect these dioxin/furan screening samples from shallow soil borings installed using direct push techniques. One soil sample will be collected from each soil boring biased to depth based on the presence of visible ash and analyzed for dioxins and furans. If ash is not observed, a soil sample will be collected from 0 to 0.5 foot below ground surface.

Soil borings will be backfilled to grade with original cuttings. After abandonment, a stake will be driven at each soil sample location.

Laboratory Analysis

The soil and associated quality control samples generated will be submitted to Eurofins Lancaster Laboratories, a New Jersey certified laboratory, for analysis. The samples will be analyzed for dioxins and dibenzofurans as indicated in Table 6.

Sample bottle requirements and preservation methods are detailed in Table 1 of the QAPP.

QA/QC samples that will be collected as part of the soil sampling program will include the following:

- One duplicate sample per each 20 field samples
- One field blank per each 10 field samples but no more than one per day
- One MS/MSD sample per sample delivery group

E&E Screening

Prior to shipping of the soil samples to the laboratory, the samples will be screened for E&E compounds. If the screening indicates concentrated E&E compounds (greater than 10%) are not present, the sediments will shipped to the laboratory. Field screening for E&E compounds will be conducted in accordance with Section 5.1 of the FQAPP.

Burning Ground Sampling Point Documentation

The locations of the Burning Ground soil boring locations will be established using a hand held GPS unit with sub-meter accuracy. Horizontal control will be referenced to the New Jersey State Plane Coordinate system (NAD 83). Vertical control will be referenced to the NGVD 1929.

Task 7 - Down-Gradient Delineation of the TNT Area Groundwater Plume

To define the maximum extent of trinitrotoluene (TNT) and its degradation products, 2-amino-4,6-dinitrotoluene (2A-DNT) and 4-amino-2,6-dinitrotoluene (4A-DNT) in groundwater, O'Brien & Gere will supervise the collection of downgradient groundwater samples from six off-Site boring locations. These

samples will be collected from soil borings installed on private (commercial) properties located southwest of the Site. The groundwater samples will be collected using a Waterloo Profiler ™ operated by Stone Environmental. O'Brien & Gere will supervise the drilling and collection of down-gradient groundwater samples. The Waterloo sample locations are indicated on the aerial photograph provided as Figure 5. Sampling depth and analytical methods are provided on Table 7. Waterloo sampling procedures are described below.

Waterloo Sampling Procedures

Groundwater samples will be collected using a modified Waterloo Profiler™ in accordance with procedures detailed in the NJDEP's 1994 *Alternative Ground Water Sampling Techniques Guide and* in the Stone SOP provided in Exhibit 2 of the QAPP. The Waterloo Profiler™ consists of a probe containing integrated sensors and sampling ports that is driven into the subsurface using direct push techniques. The integrated sensors are capable of measuring the hydraulic conductivity of the formation, hydraulic head, and physiochemical properties (pH, specific conductance, DO, and ORP). The Waterloo Profiler™ will be used to collect real time hydrostratigraphic data which will be used to ensure samples are being collected from sandy intervals. After the sampling interval is selected, the interval will be purged using an internal nitrogen gas drive pump. Physiochemical properties will be measured during the purging process to ensure formation stability prior to collecting a groundwater sample. A Geoprobe™ 66235 CPT direct push rig will be used to advance a modified Waterloo Profiler™ with minimal disturbance (i.e. minimal use of the hydraulic hammer imparting energy into the subsurface).

Groundwater samples will be collected by the modified Waterloo Profiler™ from the following discrete intervals at each location:

- 15 ft bgs,
- 30 ft bgs,
- 60 ft bgs,
- 90 ft bgs,
- 120 ft bgs.

Sampling depths may be adjusted based on hydrostratigraphic information obtained during boring installation.

Preparatory Activities

A minimum of three weeks prior to the Waterloo Profiling activities, the selected driller will submit soil boring permits to the NJDEP. The driller will notify New Jersey One Call of the planned drilling activities, a minimum of 72 hours prior to drilling, to obtain a utility mark out. Waterloo Profiling locations will be cleared by Hercules, prior to mobilization of the drill rig, to ensure drill rig access.

Laboratory Analysis

The groundwater and associated quality control samples generated will be submitted to Eurofins Lancaster Laboratories, a New Jersey certified laboratory, for analysis. The samples will be analyzed for E&E compounds as indicated on Table 7.

Sample bottle requirements and preservation methods are detailed in Table 1 of the QAPP.

QA/QC samples that will be collected as part of the off-Site groundwater sampling program will include the following:

- One duplicate sample per each 20 field samples
- One field blank per each 10 field samples but no more than one per day
- One matrix spike (MS) and one matrix spike duplicate (MSD) sample per sample delivery group

Waterloo Sampling Point Documentation

The locations of the Waterloo sample points will be established using a hand held GPS unit with sub-meter accuracy. Horizontal control will be referenced to the New Jersey State Plane Coordinate system (NAD 83). Vertical control will be referenced to the NGVD 1929.

Task 8 - Soil Sampling

Soil sampling will be conducted to delineate the vertical extent of constituents at concentrations above applicable standards, delineate the outbound extent of constituents at concentrations above applicable standards, and refine the extent of constituents at concentrations above applicable standards between individual AOCs. A total of 76 soil samples will be collected from a series of 38 soil borings. The soil borings will be installed by a New Jersey-licensed driller. The soil sample locations are indicated on Figure 4. Analytical parameter, sample depths and the rationale for the collection of the soil samples are provided on Table 8. Soil sampling procedures are summarized below.

Soil Sampling

Soil cores will be collected using a combination of hand auger and direct push (Geoprobe ™) sampling methods. Direct push soil sampling methods utilize a hydraulic hammer mounted on a truck or an all terrain vehicle to advance sampling devices into the subsurface. Soil samples collected using direct push methods will be obtained using the Macro Core (MC) sampling system. The MC sampling system consists of an open, steel tube that houses an acetate liner. The liner is held in place with a drive cap at the top and a cutting shoe at the bottom and is designed for continuous soil sample collection. If probe hole "cave-in" is significant, it may be necessary to use a closed piston assembly that fits into the MC. The closed piston assembly MC sampler remains completely closed when driven to depth and are opened by releasing a stop pin from the surface. Releasing the stop pin allows a piston to retract inside of the sample tube as it is being displaced by the sample core. The anticipated maximum depth of the soil borings is 10 feet. Direct push sampling procedures are detailed in Section 7.3.2 of the FQAPP.

After the MC sampler is retrieved, the liner will be removed and cut open to allow access to the soil core for field screening and sample collection. The soil core will be screened with a photoionization detector and logged by a geologist using the using the *Burmeister Soil Classification System*. Field screening procedures are detailed in Section 5.2 of the FQAPP.

Two soil samples will be collected from each soil boring. One soil sample will be collected from the 0 to 0.5 foot interval below the ground surface or the concrete, asphalt, or crushed stone, if the area is paved. The second sample will be taken from one of the following intervals:

- Sample depths will be biased based on visual observations and field screening with a PID
- The six-inch interval above the water table if no anthropogenic feature warranting biasing (e.g. stained soil, ash, etc.) is observed
- The base (9.5 to 10 ft bg interval) of the boring if no anthropogenic feature warranting biasing is observed and the water table is not encountered

Soil samples that will be analyzed for VOCs will be collected directly from the soil core using an Encore sampler. After the VOC sample is collected, the remaining portion of the selected sampling interval will be placed into a

decontaminated stainless steel bowl and homogenized. The soils will then be transferred from the bowl to the appropriate sample containers.

Soil borings will be backfilled to grade with original cuttings. If the soil boring extends below the water table, the portion of the soil boring below the water table will be sealed with a bentonite slurry. After abandonment, a stake will be driven at each soil sample location for later use by a New Jersey-licensed surveyor.

Laboratory Analysis

The soil and associated quality control samples generated will be submitted to Eurofins Lancaster Laboratories, a New Jersey certified laboratory, for analysis. The samples will be analyzed for VOCs, SVOCs, E&E Compounds, TAL Metals as indicated on Table 8.

Sample bottle requirements and preservation methods are detailed in Table 1 of the QAPP.

QA/QC samples that will be collected as part of the soil sampling program will include the following:

- One trip blank sample per sample shipment that requires analysis for VOCs
- One duplicate sample per each 20 field samples
- One field blank per each 10 field samples but no more than one per day
- One MS/MSD sample per sample delivery group

E&E Screening

Prior to shipping soil samples to the laboratory, the soil samples will be screened for E&E compounds. If the screening indicates significant E&E compounds are not present (greater than 10%), the sediments will shipped to the laboratory. Field screening for E&E compounds will be conducted in accordance with Section 5.1 of the FQAPP.

Soil Sampling Point Documentation

The locations of the soil borings points will be established using a hand held GPS unit with sub-meter accuracy. Horizontal control will be referenced to the New Jersey State Plane Coordinate system (NAD 83). Vertical control will be referenced to the NGVD 1929.

EQUIPMENT DECONTAMINATION PROCEDURES

All non-disposable equipment used in field sampling activities will be decontaminated before and after use. Dedicated, disposable equipment used for aqueous sampling will be decontaminated by the manufacturer. The Field Investigation Manager will ensure that appropriate decontamination procedures are followed.

Drill Rig

The drill rig and associated sampling equipment (i.e., augers, drill rods, etc.) will be decontaminated prior to arrival at the site and between at each monitoring well location prior to mobilization to the next monitoring drilling site. Decontamination of this equipment will be performed at a centralized decontamination pad. The following procedures will be used to decontaminate the drill rig and associated sampling equipment:

- The drill rig will be driven on to the decontamination pad and parked
- The associated drilling equipment (i.e. drill rods, augers, split spoons) will be staged on metal stands off the ground
- The drill rig and associated equipment will be thoroughly cleaned on the decontamination pad using a high-pressure steam cleaner and potable water
- Decontaminated equipment will be staged in a clean location prior to use

Direct Push Sampling Equipment

All direct push sampling equipment used to advance soil sampling equipment (i.e., The direct push rig, drill rods, MC etc.) will be decontaminated prior to arrival at and upon leaving the Site. Between each subsurface sampling location the drill rods and MC will be decontaminated. Decontamination of the drill rods and MC equipment can be done at the boring location.

Prior to leaving the site, the direct push rig will be thoroughly cleaned at the last boring location using a high-pressure steam cleaner and potable water. Since acetate liners are being used, the MC system and drill rods will be decontaminated by washing with a non phosphate detergent and rinsing with potable water. The drill rods and MC system will then be rinsed with distilled water. The decontaminated equipment will be placed in a clean location protected from fugitive dust prior to field use

Non-Disposable Sampling Equipment

All non-disposable sampling equipment (i.e. soil coring devices, sediment samplers, spoons, bowls, surface water samplers etc.) will be decontaminated prior to mobilization to each sampling location. The following procedures will be used to decontaminate the aqueous and manual sampling equipment:

- Equipment will be washed with potable water and non-phosphate detergent.
- Equipment will be thoroughly rinsed with potable water
- Equipment will be rinsed with distilled water
- Equipment used to collect samples for metals analysis will be rinsed with a 10 percent solution of laboratory grade nitric acid followed by another rinse with distilled water
- Equipment used to collect samples for organic analysis will be rinsed with pesticide-grade acetone rinse and air dried followed by another rinse with distilled water.
- Equipment will be wrapped in aluminum foil, shiny side out
- Information concerning decontamination methodology, date, time, and personnel will be recorded in the field logbook.

Field Measurement and Standard Purging Equipment

All field measurement equipment (i.e., static water level indicator, pH meter, conductivity meter or submersible pump) will be decontaminated prior to each use. Decontamination of this equipment will be conducted as described below:

- Equipment will be washed with potable water and non-phosphate detergent and a potable water rinse
- Submersible pumps will be cleaned with a non-phosphate detergent and a potable water rinse followed by a 10 gallon flush of potable water through the pump.
- Equipment will be rinsed with distilled water and allowed to air dry
- The decontaminated equipment will be placed in a clean location protected from fugitive dust prior to field use

.

Low Flow Groundwater Sampling Equipment Decontamination

New tubing will be dedicated for use in each well and will not require decontamination. The pumps, however, will require decontamination prior to and following use. If existing tubing is present in the well, O'Brien & Gere will remove and dispose of the tubing prior to installing the new tubing. Non-disposable sampling equipment, including the pump and support cable and electrical wires which contact the sample, must be decontaminated thoroughly each day before use ("daily decon") and after each well is sampled ("between-well decon"). Decon procedures are summarized below.

Daily decontamination of pumps will be conducted in the following manner:

- Pre-rinse: Operate pump in a deep basin containing 8 to 10 gallons of potable water for 5 minutes.
- Wash: Operate pump in a deep basin containing 8 to 10 gallons of a non-phosphate detergent solution, such as Alconox, for 5 minutes. Use the detergent sparingly.
- Rinse: Operate pump in a deep basin of potable water for 5 minutes.
- Disassemble pump.
- Wash pump parts: Place the disassembled parts of the pump into a deep basin containing 8 to 10 gallons of non-phosphate detergent solution. Scrub all pump parts with a brush.
- Rinse pump parts with potable water.
- Rinse the following pump parts with distilled/ deionized water: inlet screen, the shaft, the suction interconnector, the motor lead assembly, and the stator housing.
- Place impeller assembly in a large glass beaker and rinse with 1% nitric acid (HNO_3).
- Rinse impeller assembly with potable water.
- Rinse impeller assembly with distilled/deionized water.

Between-well decontamination of pumps will be conducted in the following manner:

- Pre-rinse: Operate pump in a deep basin containing 8 to 10 gallons of potable water for 5 minutes.
- Wash: Operate pump in a deep basin containing 8 to 10 gallons of a non-phosphate detergent solution, such as Alconox, for 5 minutes. Use the detergent sparingly.
- Rinse: Operate pump in a deep basin of potable water for 5 minutes.
- Final Rinse: Operate pump in a deep basin of distilled/deionized water to pump out 1 to 2 gallons of this final rinse water.

SAMPLE HANDLING, FIELD CUSTODY AND SAMPLE DOCUMENTATION PROCEDURES

Sample Handling Procedures

The following sample handling procedures will be utilized for all sampling events conducted at the facility:

- New disposable nitrile gloves will be used when collecting samples for chemical analysis
- As applicable, sample containers will be filled in the following order: VOCs, SVOCs, pesticides/PCBs, dioxins, metals, and water quality parameters (e.g. hardness).
- All aqueous VOC containers will be filled to zero headspace

After collection, the will be immediately placed in appropriate laboratory-supplied containers, labeled, maintained in coolers at 4°C, and will be maintained under a chain-of-custody (see below) at all times.

Environmental samples will be packed prior to shipment using the following procedures:

- Use only clean, sturdy coolers in good repair.
- Secure and tape the drain plug
- Be sure the lids on all bottles are tight (will not leak), place the bottles inside Ziploc plastic baggies and seal the baggies
- Put ice that has been placed in heavy-duty polyethylene Ziploc plastic baggies sealed on top of and between the samples to maintain the inside temperature at approximately 4 °C ±2 °C
- Pack samples securely to eliminate breakage during shipment
- When possible, sample container preparation and packing for shipment will be completed in a well-organized and clean area. Sample containers will be prepared for shipment by wiping containers clean of debris/water using paper towels. Paper towels will be disposed with the personal protective equipment (PPE).
- Place chain-of-custody record into a Ziploc plastic bag, tape the bag to the inner side of the cooler lid, and close the cooler and securely tape the top of the cooler shut.
- Two custody seals will be affixed to the latch and lid of the cooler. The number of the security seal will be recorded on the chain-of-custody form. The custody seals will consist of adhesive-backed tape that easily rips if it is disturbed. The field sampler will initial and date the seal. The seals must be broken to open the cooler and will indicate tampering if the seal is broken before receipt at the laboratory.
- A label containing the name and address of the shipper will be placed on the outside of the container.

The coolers will be delivered to the laboratory via a courier service. Prior to shipment of sample coolers, the field sampling team will contact the laboratory to notify the laboratory of the shipment.

Samples will remain in the custody of the sampler until transfer of custody is completed. Transfer consists of:

- Delivery of samples to courier and
- Signature of the courier on the chain-of-custody form as receiving the samples and signature of sampler as relinquishing the samples.

Sample Labeling

A completed sample identification label or tag will be attached to each investigative or QC sample. The identification on the label must be sufficient to enable cross-reference with the logbook. The sample label will be

filled out using waterproof, non-erasable ink and will be attached to the sample container using adhesive. The sample labels/tags will contain the following information:

- Sample location/number identification
- Site/Project name
- Date and time of sample collection
- Designation of the sample as a grab or composite
- Type of sample matrix
- Name/initials of the sampler
- Whether the sample is preserved or unpreserved
- Aanlyses to be performed

Unique sample identifications (IDs) will be provided for each sample. The sample IDs will include the matrix type, an indication they were collected during the second phase of the remedial investigation (R2), a grid square location and serial sample ID for surface water, sediment and soil samples, and monitoring well location for groundwater samples. Matrix types will be abbreviated as described below:

- GW for groundwater
- SW for surface water
- SO for soil
- SD for sediment

A typical sample ID would be SW-R2-E-16-3. This ID indicates the following:

- The sample is a surface water sample
- The sample was collected during the second phase of the remedial investigation
- the sample was collected from grid square E-16
- the sample is the third surface water sample collected from grid square E-16 during the second phase of the remedial investigation

Chain-of-Custody Procedures

Chain-of-custody procedures will be instituted and followed throughout the sampling collection process. Samples are physical evidence and will be handled according to strict chain-of-custody protocols. The O'Brien & Gere QAO must be prepared to produce documentation that traces the samples from the field to the laboratory and through analysis. USEPA has defined custody of evidence as follows:

- In actual possession
- In view after being in physical possession
- In a locked laboratory or in a secure, restricted area.

The field sampler is personally responsible for the care and custody of the sample until transferred.

Chain-of-custody records will be kept starting at the time that sample containers are placed in the coolers for transportation to the laboratory. One completed chain-of-custody record must be kept with each sample cooler at all times.

Example chain-of-custody forms are provided in the laboratory's Quality Assurance Manual (Exhibit 1 of the QAPP). The following measures will be taken when completing a chain-of-custody record:

- Chain-of-custody forms will be completed in waterproof, non-erasable ink.
- Chain-of-custody forms will be completed neatly using printed text.
- If a simple mistake is made, the error will be lined out with a single line and initialed and dated.
- Each separate sample entry will be sequentially numbered.
- The use of "Ditto" or quotation marks to indicate repetitive information in columnar entries should be avoided. If numerous repetitive entries must be made in the same column, a continuous vertical arrow will be used between the first entry and the next different entry.
- When more than one chain-of-custody form is used for a single shipment, each form will be consecutively numbered using the "Page ___ of ___" format.
- If necessary, additional instructions will be placed directly onto the chain-of-custody form.
- Acronyms used on a chain-of-custody form will be defined.

The chain-of-custody form will contain the following information:

- Project identification and number;
- Sample description/location;
- Required analysis;
- Date and time of sample collection;
- Type and matrix of sample;
- Number of sample containers;
- Analysis requested/comments;
- Sampler signature/date/time;
- Date and signature of the field representative;
- Date and signature of the laboratory representative;
- Carrier used to ship coolers; and
- Air bill number (if shipped by a commercial carrier).

In the case that high concentrations are suspected to be present in the samples, a note to that effect will be included on the chain-of-custody form.

Field Logbook Procedures

The field logbook will be used to note information regarding collection of samples and any observations. All entries will be signed and dated. Field logbooks will be waterproof and bound. The logbook will be dedicated to the project and pages will not be removed. Corrections will be made by drawing a single line through the incorrect data and initialing and dating the correction that was made to the side of the error. An initialed diagonal line will be used to indicate the end of an entry or the end of the day's activities.

The following information will be recorded in the field logbook by the field sampling team:

- Name and title of author, date, and time of site entry, physical/environmental conditions during the field activity and meteorological data;
- Project number, client name, Site name, names of field crew members, and names of visitors
- Sample media, sample collection method, including equipment utilized
- Date and time of sample collection, number and volume of samples collected, sample and QA/QC identification numbers, and required analyses
- Description of sample locations and the sampling process
- Field observations including field measurements made, equipment used, and soil logs
- Calculations, results, and calibration data for field sampling and measurements

- References for maps and photographs of the sample location
- Dates and method of sample shipments

After a field activity has been completed, copies of the field notes will be made and stored in the project file.

NOTES:

1. THESE FILES ARE IN THE NORTH AMERICAN DATUM 1983 NEW JERSEY STATE PLANE COORDINATE SYSTEM. THE TOPOGRAPHIC FILE REFERENCES THE NORTH AMERICAN VERTICAL DATUM 1988.
2. THE BOUNDARY LINE AS DELINEATED IS APPROXIMATE AND HAS BEEN DIGITIZED FROM A MAP ENTITLED "HERCULES INCORPORATED, KENVIL PLANT PROPERTY MAP, PLANT 080, ACCOUNT 9500, CLASSIFICATION 21045, FILE CODE 5WE REVISION 1" REVISED TO JUNE 11, 1970 PROVIDED BY REPRESENTATIVES OF HERCULES, INC., AND THE TAX MAP OF THE TOWNSHIP OF ROXBURY AND NOT FROM AN ACTUAL FIELD SURVEY OR WITH THE BENEFIT OF A TITLE SEARCH.
3. GROUNDWATER REMEDIAL INVESTIGATION SAMPLE LOCATIONS WERE SELECTED BASED ON ANALYTICAL RESULTS PRESENTED IN THE GROUNDWATER SITE INCESTIGATION(GW–SI) REPORT (MWH, 2004). SURFACE WATER REMEDIAL INVESTIGATION SAMPLE LOCATIONS WERE SELECTED BASED ON ANALYTICAL RESULTS PRESENTED IN THE SURFACE WATER/SEDIMENT SITE INVESTIGATION (SW/SD–SI) REPORT (MWH, 2004).
4. SAMPLE LOCATIONS PRESENTED IN THIS FIGURE WERE COLLECTED DURING THE REMEDIAL INVESTIGATION.
5. SOLID BROWN LINES REPRESENT DRY STREAM SEDIMENTS OR FORMER DITCHES THAT NO LONGER CONVEY WATER SINCE MANUFACTURING OPERATIONS HAVE CEASED. THESE AREAS ARE NO LONGER CONSIDERED SURFACE WATER OR SEDIMENT BODIES AND ARE CONSIDERED SOIL IN THE REMEDIAL INVESTIGATION REPORT.
6. DASHED BROWN LINES REPRESENT STREAM SEDIMENTS OR AREAS WITHOUT SUFFICIENT WATER PRESENT FOR SURFACE WATER SAMPLE COLLECTION, HOWEVER SATURATED SEDIMENTS ARE PRESENT.
7. MW–5P AND MW–22 COULD NOT BE SAMPLED DUE TO DAMAGE INCURRED DURING DEMOLITION EFFORTS.
8. PLAN ADAPTED FROM DRAWING TITLED "GROUNDWATER – SAMPLE LOCATION MAP" AS PRESENTED IN THE REMEDIAL INVESTIGATION REPORT, VOLUME C – GROUNDWATER FIGURE C–1 PRODUCED BY MWH AMERICAS, INC..

NOTES:

1. THESE FILES ARE IN THE NORTH AMERICAN DATUM 1983 NEW JERSEY STATE PLANE COORDINATE SYSTEM. THE TOPOGRAPHIC FILE REFERENCES THE NORTH AMERICAN VERTICAL DATUM 1988.
2. THE BOUNDARY LINE AS DELINEATED IS APPROXIMATE AND HAS BEEN DIGITIZED FROM A MAP ENTITLED "HERCULES INCORPORATED, KENVIL PLANT PROPERTY MAP, PLANT 080, ACCOUNT 9500, CLASSIFICATION 21045, FILE CODE 5WE REVISION 1" REVISED TO JUNE 11, 1970 PROVIDED BY REPRESENTATIVES OF HERCULES, INC., AND THE TAX MAP OF THE TOWNSHIP OF ROXBURY AND NOT FROM AN ACTUAL FIELD SURVEY OR WITH THE BENEFIT OF A TITLE SEARCH.
3. DASHED TOPOGRAPHIC CONTOURS INDICATE AREAS WHERE THE GROUND IS OBSCURED BY DENSE TREES OR SHADOWS. THESE AREAS MAY NOT CONFORM TO ACCURACY STANDARDS.
4. SEDIMENT REMEDIAL INVESTIGATION SAMPLE LOCATIONS WERE SELECTED BASED ON ANALYTICAL RESULTS PRESENTED IN THE SURFACE WATER/SEDIMENT SITE INVESTIGATION (SW/SD-SI) REPORT (MWH, 2004).
5. FOURTEEN SEDIMENT SAMPLES WERE PROPOSED IN THE REMEDIAL ACTION WORK PLAN THAT WERE NOT COLLECTED BECAUSE THESE SAMPLES WERE LOCATED IN AREAS WHICH WERE BACKFILLED DURING SITE IMPROVEMENT ACTIVITIES OR WERE LOCATED OFF-SITE. THESE SAMPLES ARE: A1SED-001, D-001, D-004, D-016, M-037, M-038, NGP-002, NGP-004, TNT-010, TNT-011, TNT-012, TNT-013, MIS-049, MIS-058.
6. SOLID BROWN LINES REPRESENT DRY STREAM SEDIMENTS OR FORMER DITCHES THAT NO LONGER CONVEY WATER SINCE MANUFACTURING OPERATIONS HAVE CEASED. THESE AREAS ARE NO LONGER CONSIDERED SURFACE WATER OR SEDIMENT BODIES AND ARE CONSIDERED SOIL IN THE REMEDIAL INVESTIGATION REPORT.
7. DASHED BROWN LINES REPRESENT STREAM SEDIMENTS OR AREAS WITHOUT SUFFICIENT WATER PRESENT FOR SURFACE WATER SAMPLE COLLECTION, HOWEVER SATURATED SEDIMENTS ARE PRESENT.
8. SITE INVESTIGATION SEDIMENT SAMPLE LOCATIONS DENOTED IN PURPLE ARE INCLUDED IN VOLUME B - SOIL REMEDIAL INVESTIGATION. THESE SAMPLES ARE NO LONGER CONSIDERED AS SEDIMENTS AND ARE MORE PROPERLY DEFINED AS SOILS.
9. PLAN ADAPTED FROM DRAWING TITLED "SEDIMENT - SITE WIDE AREAL EXTENT OF EXCEEDANCES" AS PRESENTED IN THE REMEDIAL INVESTIGATION REPORT, VOLUME D - SEDIMENT FIGURE D-1 PRODUCED BY MWH AMERICAS, INC..

1.0 INTRODUCTION

Hercules Incorporated (Hercules) proposes to conduct a facility-wide site investigation of the Kenvil Works facility to fulfill obligations of a Remedial Agreement (RA) with the New Jersey Department of Environmental Protection (NJDEP). The RA was signed on March 10, 1995. The facility-wide investigation is designed to comply with New Jersey Administrative Code (N.J.A.C.) 7.26E-3.3 through 3.12 and will include a series of phases addressing each media. Sampling and analysis requirements for each investigation phase will be described in a Phase-specific Sampling and Analysis Plan (SAP). Figure 1-1 illustrates the relationship of the FQAAP to all other project workplan documents.

The objective of the facility-wide investigation is to systematically assess the site to identify evidence of facility-related contamination. The investigation will include the following phases:

- Phase I - Site Screening
- Phase II - Confirmation/Delineation
- Phase III - Groundwater Assessment/Monitoring
- Phase IV - Remedial Investigation and Related Studies

This Field *Quality Assurance Project Plan* (FQAPP) describes the field procedures and protocols to be followed during the implementation of all Industrial Site Recovery Act (ISRA) related site investigation activities conducted at the Kenvil Works Facility (facility) located in Kenvil, New Jersey. This document is intended to solely address field sampling and screening methodologies in support of the facility-wide investigation described in the Technical Memorandum submitted to the NJDEP in July, 1998. The *Analytical Quality Assurance Project Plan* (AQAPP), companion document to the FQAPP and previously submitted under separate cover, describes the quality assurance/quality control (QA/QC) procedures for all analytical activities conducted for the facility-wide investigation.

This document has been prepared following requirements set forth in the *NJDEP Technical Requirements for Site Remediation* (N.J.A.C. 7:26*E,* 1997) and *the NJDEP Field Sampling Procedures Manual,* (NJDEP, 1992). Significant future modifications to the procedures

outlined in this FQAPP will be promptly reported to the Project Manager and Investigation Manager. As necessary, the Project Manager/Investigation Manager will submit significant modifications for final approval to Hercules. Upon approval, Hercules will submit these modifications to NJDEP for review and approval.

2.0 KENVIL WORKS FACILITY BACKGROUND

The facility dates back to the 1870's when it was opened for the manufacture of dynamite primarily to support the iron ore mining operations in the surrounding area. The facility was operated by various companies until 1912 when Hercules became the sole owner.

The facility is located on Howard Boulevard approximately 0.5 miles northwest of the center of Kenvil in Morris County, New Jersey. Figure 2-1 illustrates the location of the site with respect to Roxbury Township. Figure 2-2 provides a general layout of the plant Areas of Investigation (AOI). The plant is located approximately 40 miles west of New York City and 30 miles east of the Delaware Water Gap.

The plant's production areas are centrally located in a relatively flat area with a slope extending to Howard Boulevard on the north side and a ridge on the south side that separates the production area from the Berkshire Valley area. The property contains wet areas and has a lake known as "Duck Pond" which is approximately 7 acres in size.

The facility has produced a variety of explosive and propellant (energetic) related products for both military and commercial applications. In the early 1900's, the plant produced trinitrotoluene (TNT) in support of World War I activities along with other ordnance-related materials. The production of materials for military applications was expanded during World War II to include smokeless powder for both the United States and Great Britain. During the 1980's, the explosive industry began using Ammonium Nitrate/Fuel Oil (ANFO) in many explosive applications. Ammonium Nitrate manufacturing operations were installed and slurry explosive trucks operated out of the facility. The facility has also maintained a research and development area and has produced special products such as initiating materials, ingredients for medical applications, and materials for actuating devices.

The principal product over the last 20 years, smokeless powder, was most recently produced by Alliant Techsystems (Alliant) under a facility lease agreement. The principal processing areas for this activity include the Nitroglycerin (NG) Area, the A-Line production area, the B-Line production area, and the Finishing Area. Material handling areas at the facility include both loading and unloading areas which were used to unload incoming raw

materials and load finished product for shipment by truck. Support areas at the facility included office space, plant laboratories, maintenance areas, a power house, mixed acid areas, drum storage areas, a wastewater treatment plant (WWTP) and warehouses.

In 1995, Hercules sold the smokeless powder business to Alliant, who operated the facility until December 31, 1996. Hercules re-acquired control of the facility on January 1, 1997 and as the property owner is responsible for the remediation and closure of the facility for sale or reuse.

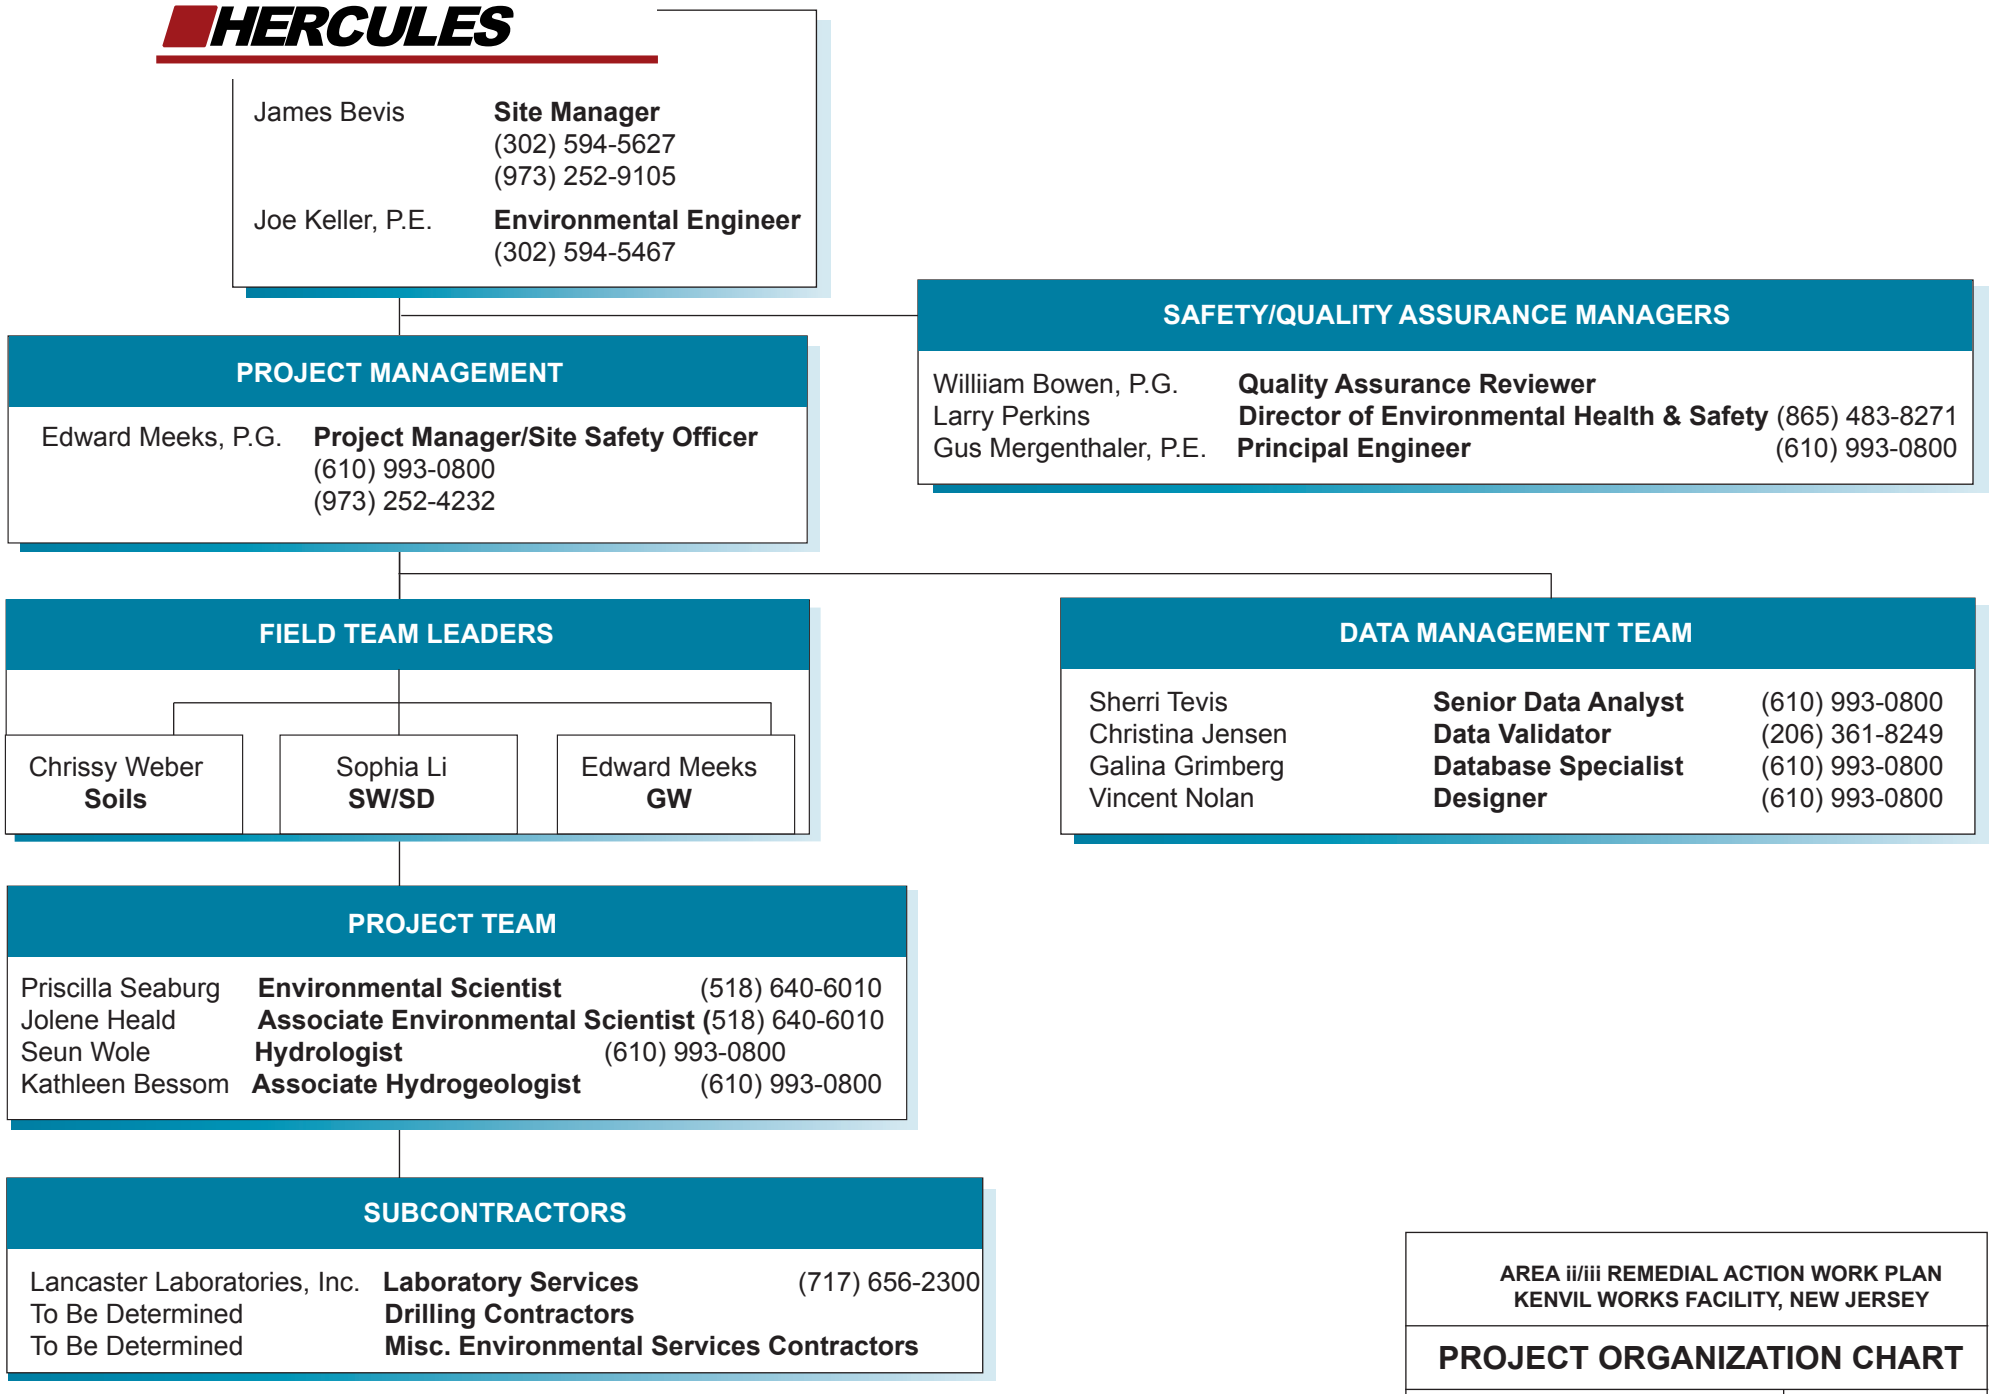
During the time Alliant operated the facility, Hercules entered into a voluntary agreement with the State of New Jersey to investigate the contamination level at the TNT area. The ISRA requirements were triggered when Alliant terminated the lease for the facility.

3.0 KEY PERSONNEL AND RESPONSIBILITIES

The project team consists of personnel from Hercules, MWH and various subcontractors. The work outlined in this FQAPP will be managed and primarily conducted by MWH, Hercules' environmental consultant for the project. Figure 3-1 presents the project organization, outlining key assignments that have been designated for this project, and the individual responsible for each assignment. A summary of the assignment responsibilities is provided below:

Project Manager: The Project Manager is responsible for the overall direction, coordination, technical consistency, and review of the entire program. The Project Manager will monitor the performance of project staff with the assistance of the Investigation Manager and Safety/Quality Assurance Managers. The Project Manager will serve as the primary point of contact for Hercules, and be responsible for contractual obligations, management oversight and problem resolution, monitoring schedule and cost, and progress reporting. The Project Manager will also serve as the primary MWH representative for critical regulatory interactions.

Investigation Manager: The Investigation Manager reports directly to the Project Manager and acts as the day-to-day point of contact for the investigation development and implementation activities. The Investigation Manager will be fully responsible and accountable for implementation of technical and scheduling activities. In coordination with the Field Team Leader, the Investigation Manager will oversee project tasks, coordinate subcontractors, and monitor the schedule and costs of major investigation-related project elements. The Investigation Manager will also ensure that necessary resources are made available (including personnel, materials, and equipment), and potential problems or conflicts are identified and resolved in a timely manner. The Investigation Manager will be responsible for technical implementation of the project and application of project quality control (QC) procedures.



AREA ii/iii REMEDIAL ACTION WORK PLAN
KENVIL WORKS FACILITY, NEW JERSEY

PROJECT ORGANIZATION CHART

MWH

FIGURE 3-1

Field Team Leader: The Field Team Leader reports to the Investigation Manager and is responsible for project set-up of field support services. The Field Team Leader will provide oversight of field investigation tasks.

Technical Reviewers: The Technical Reviewers will, as necessary, provide technical assistance and review and other functions as necessary to ensure compliance with the QAPP. The technical reviewers will be responsible for the overall quality of deliverables.

Data Validator: The Data Validator will review all analytical data reported by the laboratory to identify errors and to flag or qualify suspect data prior to its use in making decisions about the site. Specifics concerning the data validation process are presented in Section 4.2 of the AQAPP.

Project Safety Officer (PSO): The PSO has been responsible for the preparation of the Site Specific Health and Safety Plan (SSHSP), and will be responsible for the implementation of the SSHSP. The PSO will provide the overall direction regarding matters of environmental protection, fire protection, occupational safety and health, industrial hygiene, personal protection from hazardous chemical exposure, and health and safety monitoring for this project. The PSO has the organizational authority to require changes to work practices, identify problems and propose solutions and, if necessary, stop work activities that could pose a threat to personnel or the environment. The PSO will coordinate activities with the Project Manager or Investigation Manager, as appropriate.

Site Safety Officer (SSO): The SSO is responsible for field implementation of the SSHSP and enforcement of safety rules and regulations. The SSO activities may be performed by the PSO. The SSO will handle liaison with subcontractors on matters relating to health and safety. Other site-specific SSO functions include:

- Verify that utility clearance has been performed.
- Oversee day-to-day implementation of the FQAPP by subcontractor employees.
- Interact with subcontractor project personnel on health and safety matters.
- Determine levels of protection.

- Verify that MWH and subcontractor site personnel have received proper training and participate in a medical surveillance program.
- Provide on-site training to MWH and subcontractor site personnel on health and safety matters that develop during the project.
- Modify the FQAPP as needed and notify appropriate persons of changes.
- Inspect and maintain (daily) safety equipment including calibration of air monitoring instrumentation.
- Perform or direct ambient air quality monitoring as warranted.
- Investigate and report on-site accidents/incidents.
- If MWH employees enter excavations, act as the competent person and ensure OSHA excavation requirements are enacted.
- Verify that MWH and subcontractor site personnel are familiar with the hospital route, and that the route map is posted in the work trailer or site vehicles.
- Establish detailed procedures and routes for evacuation from the site.
- Establish the Exclusion, Decontamination and Support Zones at the site, as necessary, and provide means of securing the work area.
- Implement and direct confined space entry procedures, as necessary.

The SSO will report accidents such as injury, overexposure, or property damage to the PSO, and will consult with the PSO on specific health and safety issues arising over the course of the project.

4.0 FIELD DATA QUALITY OBJECTIVES

The success of sampling activities performed during the field investigation program will be evaluated based on specific data quality objectives (DQOs). These DQOs are quantitative and qualitative statements that stipulate the level of data quality required of the project and each component of the project. Quantitatively, DQOs are expressed in terms of precision, accuracy, representativeness, completeness and comparability (PARCC). In general, DQOs measure the performance of the sampling and analytical procedures.

For example, the data quality associated with environmental measurements can be considered a function of sampling variability. This includes the sampling plan rationale, sample collection procedures and analytical variability, the latter which may be attributed to analytical performance and the instrumentation used in making the measurements. The sampling and analytical activities may introduce potential sources of uncertainty or biases that may affect the overall confidence in the analytical measurement.

When reviewing field sampling DQOs, the evaluation is partially qualitative and its primary purpose is to address the impact of field method nonconformances on the associated data. This section addresses PARCC criteria specifically associated with field sampling activities. The PARCC criteria as they relate to the field investigation are described in the following sections and summarized in Table 4-1.

4.1 PRECISION

The evaluation of sampling precision is based on sample collection, handling and transportation procedures. During the field sampling program, changes or nonconformances in the planned collection, handling and transportation procedures may cause variability in the resulting analytical data. To reduce sampling-derived variability, detailed planning and field protocols will be developed in the phase-specific SAPs. For example, field duplicate samples do not specifically address field variability, such as sample heterogeneity, but do provide general information on the overall precision of sampling and analytical measurements. In this regard, the evaluation of sampling precision for the field investigation program is qualitative and identifies possible sampling problems that may induce variability

Table 4-1

Data Quality Objectives (DQO) Summary
Field Quality Assurance Project Plan

Kenvil, New Jersey

Parameter	DQO Goal	Actual	DQO met?	Comments
Field Measurments (Non Water Level) To Within 0.1 Foot.	100%	*TBD	*TBD	*TBD
Water Level Measurements To Within 0.01 foot.	100%	*TBD	*TBD	*TBD
Water Level Measurements Collected From Consistent Reference Point.	100%	*TBD	*TBD	*TBD
Perform All Aspects Of Well Design And Development.	100%	*TBD	*TBD	*TBD
Consistent Soil Logging Procedures.	100%	*TBD	*TBD	*TBD
Measuring All Specified Parameters During Sampling.	100%	*TBD	*TBD	*TBD
Consistent Criteria Used For Selecting Samples For Chemical Analysis.	100%	*TBD	*TBD	*TBD
Completely Filling Out Field Documentation.	100%	*TBD	*TBD	*TBD
Entering Precise Measurements Into Field Documentation.	100%	*TBD	*TBD	*TBD
Calibrate Field Measurement Equipment To Manufactures Specifications.	100%	*TBD	*TBD	*TBD
Consistent Utilization Of Field Measurement Instruments.	100%	*TBD	*TBD	*TBD

in the analytical data. This precision evaluation includes assessing whether the correct number of field duplicate and field QA/QC samples required by the AQAPP were collected during the field investigation program. All of these aspects will allow the overall precision of the data to be evaluated after the analytical program is completed and laboratory data results are compared to the laboratory DQOs established in the AQAPP.

Specifically, however, precision of field data can be ensured by adhering to standards of precision established for each field measurement procedure. Examples of this include:

- measuring water levels to a certain level of precision;
- calibrating field measurement instruments to manufacturer's standards;
- making measurements from consistent measuring points; and
- entering precise measurements on all field documentation forms, including the use of consistent descriptive terminology.

4.2 ACCURACY

Sampling program accuracy, or the bias in the measurement systems inherent to the program, will be evaluated through the collection and analysis of matrix spike (MS) and matrix spike duplicate (MSD) samples during the field investigation program at the frequency identified in the AQAPP. The results from MS and MSD samples, Laboratory Control Samples (LCS) and surrogate spike samples, that are prepared in the laboratory, will be used to assist in the assessment of the accuracy of the field program.

Although the evaluation of field investigation program sampling accuracy is partially limited to a qualitative evaluation of field performance, satisfactory field performance will also be evaluated based on the quantitative standards of accuracy adhered to in conducting specific field measurements. Accuracy of field measurements will be ensured by:

- Maintaining accurate drilling logs, Chain of Custody Records (COCs), monitoring well diagrams and other field data forms;
- Properly calibrating and maintaining field measurement instruments to ensure accurate measurements are taken; and
- Properly implementing field measurement instruments in a consistent manner to ensure accurate measurement.

4.3 REPRESENTATIVENESS

The representativeness of the sampling program will be based on whether or not the resulting analytical data are characteristic of conditions and compound concentrations present at the site. In order to obtain data representative of the site, field samples will be collected from potentially contaminated environmental media. Samples will be collected using procedures and methods that attempt to maintain the integrity and consistency of the sampling process. The evaluation of representativeness will be qualitative with respect to the design of the sampling program and will serve to provide confidence that contaminant concentrations detected in field samples represent actual concentrations present in each respective media.

Representativeness will be evaluated quantitatively through the use of trip blanks. Trip blanks, as specified in the AQAPP, will be prepared in the laboratory and kept with other sample containers for the duration of their shipment, or "trip" from the laboratory to the field and back to the laboratory. The trip blank samples will provide an indication of contamination that may have been introduced during the collection, handling and transportation of the sample. In addition, lithologic descriptions will be made of each soil sampling interval to ensure that analytical data can be associated with stratigraphic information. The lithologic characteristics of the samples will be important for resolving analytical anomalies and for evaluating the representativeness of the data in terms of site conditions and contamination distribution.

4.4 COMPLETENESS

The completeness of the sampling activities is a quantitative measure which will be measured as a percentage of the total samples, including QA/QC samples, collected versus the total samples planned for collection in the SSSAP. Missing data can result from many unforeseen circumstances, including sample collection problems, sampling location accessibility problems and sample breakage. Incomplete sample sets (i.e., field and QC samples) may affect sample completeness and the degree of confidence that contamination may or may not exist within a given medium in a specific location.

Field data completeness will be evaluated to ensure that an appropriate quantity of field measurements are taken and recorded. Field data will be used to develop a conceptual understanding of the site and to provide supporting information for resolving any sampling-related concerns generated by laboratory analytical results. Completeness will be ensured in the field by thoroughly conducting sampling and measuring activities in accordance with established procedures. This will include activities such as:

- Consistently logging soil samples at predesignated intervals;
- Selecting soils for chemical analysis using the same criteria for selection;
- Performing all aspects of well design construction and development;
- Measuring all specified parameters during sampling; and
- Filling out all field data forms fully and correctly.

4.5 COMPARABILITY

The comparability of field investigation program data will be evaluated qualitatively and will consider the confidence with which one data set can be compared with another. Comparability is an evaluation of whether field data, as a function of the field sampling techniques and measurement units of the field equipment, can be directly compared with data collected during previous or future sampling events at the same site. Comparability will be ideally achieved by developing and consistently using approved sample collection, handling and analytical procedures. Sample collection and handling procedures, and the consistent use of these procedures, are discussed in the following sections.

5.0 FIELD SCREENING METHODS

Field screening methods will be used throughout the facility-wide investigation to evaluate the major site media for explosive and energetic (E&E) safety and the presence of specific non-E&E contaminants. Screening data will be generated by rapid, lower precision methods of analysis than the definitive data produced by fixed based laboratory analysis and will be documented within the field notebooks. Screening data will be utilized to bias analytical samples to locations of highest potential contamination and determine the vertical and horizontal limits of areas for which remediation and analysis by a certified laboratory is necessary. At least 10 percent of the screening data will be confirmed by a certified fixed based laboratory. The specific use of the screening methods will be identified in the phase-specific SAPs that will be prepared for each phase of investigation. Table 5-1 presents the field screening methods and identifies the uses of each method. The following subsections describe the field screening methods that may be utilized during the facility-wide investigation.

5.1 EXPLOSIVE AND ENERGETIC COMPOUNDS

To ensure the safety of field and laboratory personnel field screening for the presence of E&E compounds will be conducted prior to the collection of any soil, sediment, waste, or unknown material sample. Field screening will be required since the facility has manufactured, or otherwise managed, E&E compounds at various locations for more than 100 years. Figure 5-1 depicts the E&E compound screening process.

Field screening for E&E compounds will be conducted as follows:

- Upon arriving at the selected sample location, the field team will visually inspect the ground surface for the presence of E&E compounds. If E&E compounds are visually identified, the area will be isolated for future remedial efforts and no sample will be collected. If no E&E compounds are visually identified, then the proposed sampling can be initiated. Isolation will consist of placing temporary barriers fixed with red danger barricade tape around the impacted area to alert personnel of the potential danger associated with the E&E compounds.
- Once the surface soils are visually determined to be free of E&E compounds, the area to be sampled will be wetted with distilled water. The distilled water will

SVOCs - Semi-Volatile Organic Compounds
E&E - Explosives and Energetics

help desensitize potential E&E compounds not identified below the ground surface, allowing safe sample collection to begin. Sample collection methods are described in Section 6.0.

- Visual observation for the presence of E&E compounds must be conducted throughout the entire sample collection activity. If E&E compounds are visually identified at any time during the sampling event, the sampling activity will be discontinued immediately and the area will be isolated with red barricade tape for future remedial efforts and no sample will be collected. If no explosives are visually identified during the sampling event, the sample material will be evaluated for the presence of E&E compounds using the EX-PRAY® E&E compounds detection test kit.

- The EX-PRAY® E&E compound detection test kit is an aerosol based technique that utilizes a patented paper and colorimetric reaction to identify E&E compounds at residual levels. This kit can differentiate between polynitro-aromatics (TNT, picric acid, etc.), nitrate esters (nitroglycerin (NG), nitrocellulose (NC), etc.), and Nitramines {cyclotrimethylenetrinitramine (RDX), cyclotetramethylenetetranitramine (HMX), etc.}. The EX-PRAY® kit, however, does not provide contaminant concentration data, it is designed only to determine if E&E compounds are present in ranges from residual levels to near percentage concentrations. The manufacturers' information and instructions for performing the EX-PRAY® tests is included as Appendix A. If no E&E compounds are detected, it will be considered safe to fill the appropriate sample containers and ship the samples to the laboratory. If E&E compounds are detected, the collected sample will then be screened with the Dtech® E&E compounds test kit.

- The Dtech® E&E compounds test kit is an immunoassay technology that utilizes an antibody specific to TNT and related compounds to determine the relative concentration of E&E compounds. While the Dtech® test kit was first developed to identify TNT in soil and water, it has been successfully utilized to determine the relative concentration of other E&E compounds in relation to a TNT equivalent. The Dtech® test kit utilizes a color developing solution that is inversely proportional to the concentration of TNT equivalents. The concentration of the TNT or equivalent is determined by comparing the color of the test kit to a standardized color chart. The Dtech® manufactures' information and instructions for performing the Dtech® tests is included as Appendix B. If the sample material contains less than 1% E&E compounds it will be considered safe to fill the appropriate sample containers and ship the samples to the laboratory. If greater than 10% E&E compounds are present, the material will be considered unsafe to ship to the laboratory for analysis and the area will be isolated for future remedial efforts. If the sample material contains between 1% and 10% E&E compounds, spot tests for NG, pentaerythritol tetranitrate (PETN), and Diazodinitrophenol (Diazo) must be performed. Spot tests for NG, PETN, and Diazo are required because these compounds are more sensitive than most E&E compounds and for safety reasons will not be shipped for analysis if they are present above a concentration of 1%.

- Spot tests are a variety of specific reagent-based colorimetric analyses developed by the U.S. Department of Defense (DOD) to facilitate a quick and effective procedure to identify unknown E&E compounds. Since NG, PETN, and Diazo are the only explosive compounds that represent a safety concern between 1% and 10%, the spot tests will be limited to these compounds. The procedures for spot testing for NG, PETN, and Diazo are described in Chapter 12 of the Military Explosives Manual, which is included as Appendix C. If NG, PETN, or Diazo are detected the sample material will be considered unsafe to ship to the laboratory for analysis and the area will be isolated for future remedial efforts. If NG, PETN, or Diazo are not detected, the sample material will be considered to be comprised of secondary explosives and, therefore, safe to ship to the laboratory for analysis since the total concentration of E&E compounds will be below the established safe limit of 10%.

If a sample is determined to be unsafe for shipment to or analysis by a laboratory the sample will be immediately returned to the collection point. The area will be marked by fencing or suitable flagging to identify the area as containing explosive hazards and will be restricted to authorized personnel only. The area containing the explosives will be immediately evaluated to determine if an interim remedial measure (IRM) is warranted or if the area poses minimal potential for imminent physical hazard, contaminant migration, and impact to groundwater. If it is determined that the explosive constituents do not pose an imminent physical hazard, are not mobile, and will not impact site groundwater the remedial efforts will be deferred until a Site-Wide Phase II Confirmation/Delineation effort is conducted.

Personnel involved in site activities conducted at the facility will receive initial or refresher E&E compound safety education prior to commencement of any work. The site E&E compound safety education will be directed by the MWH PSO and the Hercules PSO. This education will be designed to provide employees with a thorough knowledge and the ability to identify E&E compounds that may potentially be encountered on-site. All personnel new to the site will be required to receive this training before they are permitted to undertake field activities.

5.2 VOLATILE ORGANIC COMPOUNDS

Field screening for the presence of volatile organic compounds (VOCs) will be conducted continuously during the collection of soil, sediment, waste or unknown material samples. The field screening will be accomplished with a flameionization (FID)/photoionization detector (PID) utilizing a standard 10.6 electron volt lamp. In the event VOC constituents with a greater than 10.6 electron volt ionization potential, such as methane, are anticipated a suitable lamp will be exchanged or an alternate screening device will be utilized. The results of the field screening will be documented in the field logbook.

The primary advantage to screening soil samples with the FID/PID is rapid determination of the presence of VOC constituents so that appropriate field decisions can conducted.

5.3 SEMI-VOLATILE ORGANIC COMPOUNDS

Immunoassay tests may be utilized during the field investigation to screen for the presence of semivolatile organic compounds (SVOCs). The test involves utilizing laboratory provided antibody-coated test tubes specifically designed for a particular class of SVOC compounds. An aliquot of sample material is placed into the test tubes and reacts with the antibody coating on the test tube inducing a color change within the test tube. The concentration of the targeted analyte is determined by comparing the color of the material within the test tube to a color standard calibrated to various concentrations of the targeted analyte.

The advantage of using immunoassay tests is the high sensitivity and specificity bias filters compounds not being tested for and produces detection results at the ppm, ppb, and ppt levels so that appropriate field decisions can be made. Appendix D contains the manufacturers' information on SVOC immunoassay test kits.

5.4 INORGANIC COMPOUNDS (METALS)

X-Ray Fluorescence (XRF) spectrophotometry has been identified as the most applicable screening methodology for identification of metals that may be employed during the proposed facility-wide investigations.

Field XRF analysis is used to produce real time data (i.e., provide analytical data within minutes to tens of minutes) to assess subsequent courses of action during the delineation of the vertical and lateral extent of contamination. Developed in the early 1970's, XRF is a flexible elemental analysis method used for qualitative and quantitative composition determinations of solid, liquid, thin film and powder samples. XRF spectrophotometry is capable of analyzing elements with atomic number 11 (sodium) and higher in the periodic table in concentrations ranging from a few ppm to 100 percent by weight.

Several advantages of the XRF method compared to other elemental analysis techniques are non-destructiveness, little or no sample preparation, rapid analysis turnaround time, and straightforward interpretation of X-Ray emission spectra acquired from a sample. Appendix E contains the MWH standard operating procedure (SOP) for performing XRF analysis.

5.5 PESTICIDE AND POLYCHLORINATED BIPHENYL (PCB) COMPOUNDS

Immunoassay tests may be utilized during the field investigation to screen for the presence of pesticides and PCBs. The tests are similar to the SVOC screening test kits and involve utilizing laboratory provided antibody-coated test tubes specifically designed for a particular class of pesticide and PCB compounds. An aliquot of sample material is placed into the test tubes and reacts with the antibody coating on the test tube inducing a color change within the test tube. The concentration of the targeted analyte is determined by comparing the color of the material within the test tube to a color standard calibrated to various concentrations of the targeted analyte.

The advantage of using immunoassay tests is the high sensitivity and specificity bias filters compounds not being tested for and produces detection results at the ppm, ppb, and ppt levels so that appropriate field decisions can be made. Appendix D contains the manufacturers' information concerning SVOC immunoassay test kits.

6.0 REMOTE SENSING TECHNIQUES

Remote sensing techniques may be used during the facility-wide investigation to help define subsurface conditions utilizing terrestrial, borehole and aqueous geophysical techniques. The objective of the remote sensing techniques is to safely define subsurface geology, locate buried objects, define remnant subsurface features such as former ditches, and potentially locate groundwater contaminant plumes. Table 6-1 presents the remote sensing techniques and their various uses. This section describes the major remote sensing geophysical techniques that may be utilized during site investigation activities at the facility.

6.1 TERRESTRIAL TECHNIQUES

The terrestrial techniques consist of remote sensing methods that are conducted at the ground surface with the purpose of broadly evaluating subsurface conditions. The following is a description of the terrestrial techniques that may be employed during the facility-wide investigation.

6.1.1 Ground Penetrating Radar Method

The Ground Penetrating Radar (GPR) method utilizes high frequency radio waves to obtain subsurface information to identify buried objects or define shallow subsurface stratigraphy. The process involves slowly pulling across the ground surface a small antenna (generally mounted on a sled) that emits high frequency radio waves. The radio waves penetrate the subsurface and are reflected back to the surface and collected by a receiving antenna, also located on the sled. The variations within the return radio wave signal are continuously recorded and provide a cross-sectional view of the shallow subsurface.

The depth of penetration for the high frequency radio waves are highly site-specific and are primarily affected by moisture, density and conductivity of the soils encountered. Generally, GPR has a functional depth from 1 to 10 meters below grade.

Table 6-1

Summary of Terrestrial Geophysical Techniques
Field Quality Assurance Project Plan
Facility-wide Investigation
Kenvil Works Facility, New Jersey

Geophysical Method	Locate Buried Objects	Define Subsurface Geology/Stratigraphy	Identify Contaminant Plumes
Ground Penetrating Radar	□√	□√	
Electromagnetics	□√	□√ [1]	√
Resistivity	□√	√	□√
Seismic Refraction	□√ [2]	√	
Seismic Reflection	□√ [2]	√	
Magnetometer	□√		

(1) Method mainly used to differentiate overburden from bedrock.
(2) Method can locate large buried objects.

6.1.2 Electromagnetic Method

The electromagnetic (EM) method measures differences within the electrical conductivity of subsurface soils to locate buried objects, former ditches, and potential groundwater contaminant plumes. This method utilizes a transmitter coil emitting an electromagnetic field into the subsurface that induces currents of electromagnetic energy within the subsurface. Each of these currents generates a secondary electromagnetic field proportional to the magnitude of the primary current. A portion of the secondary electromagnetic field generated is measured by a second receiver coil located at the ground surface. The measurement collected by the receiver coil is a bulk conductivity measurement of the total sampling depth.

The sampling depth of the electromagnetic method is controlled by the spacing of the instrument's coil. The common sampling depths are 1, 4, 10, 20, and 40 meters below the instrument.

6.1.3 Resistivity Method

The resistivity method measures the electrical resistivity of the subsurface to differentiate geologic media, locate buried wastes, and locate groundwater contaminant plumes. Application of this method requires that an electrical current be introduced into the subsurface from a pair of surface electrodes. A second pair of surface electrodes measures the voltage of the electrical field introduced by the first pair of electrodes. The resistivity is then calculated by using the electrode separation, geometry of electrodes, applied current, and measured voltage.

The sampling depth of the resistivity method is controlled by the porosity and permeability of the subsurface, amount of pore water, concentration of constituents within the pore water and the geometry of the electrodes. Sampling depths are possible to 100 meters below the instrument, if conditions are favorable.

6.1.4 Seismic Refraction Method

The seismic refraction method measures the length of time required for seismic waves to leave the energy source, travel to and refract off subsurface interfaces, and return to the ground surface. This method is used to define subsurface horizons such as the water table, stratigraphic boundaries, or top of bedrock. In addition to natural properties, seismic refraction methods have historically been used to detect the existence of large anomalies within discrete layers, such as drum disposal areas.

Utilization of this method requires an energy source to initiate a seismic impulse directed downward into the subsurface. Once transmitted, the wave travels to subsurface interfaces and is refracted back to the surface. Geophones (seismic recorders) are arranged on the surface to receive and translate the wave energy into an electric signal. Signals are then enhanced and recorded by a seismograph. Analysis of seismic wave travel time as a function of distance from the seismic source is used to define the subsurface conditions. The limiting factor of the seismic refraction method is that overall geophone line-length must be three to five times the maximum depth of interest and seismic velocity must increase with depth. Seismic refraction can be useful from less than 10 meters to several hundred meters below the instrument.

6.1.5 Seismic Reflection Method

The seismic reflection method is similar to the seismic refraction method, with the exception that seismic waves reflected from subsurface interfaces are targeted and the geophone line length is not nearly as long. This method is also used to define subsurface horizons such as the water table, stratigraphic boundaries, or top of bedrock. The seismic impulse directed downward is reflected from subsurface horizons such as lithological boundaries or erosional surfaces. Generally reflected seismic waves are lower in energy than refracted seismic waves and require a significant amount of computer amplification and filtering to be useful. Cross sections constructed from the seismic reflection data can yield subsurface information from the near surface to several hundred meters below surface.

6.1.6 Magnetometer Method

The magnetometer method measures the intensity of the earth's magnetic field to locate the presence of ferrous metal objects such as buried drums, pipes, or other metal debris. This method is based on the principle that ferrous metals create localized variations in the earth's magnetic field measurable by the magnetometer.

The effectiveness of the magnetometer can be reduced by natural changes in the earth's magnetic field, magnetic minerals in the subsurface, and nearby ferrous objects such as buildings or pipes. Typically, the magnetometer can be used define ferrous objects the size of a typical 55-gallon drum to a depth of 6 meters. If a large mass of ferrous material is present, such as a multiple drum disposal area or a large tank, detection depths to 20 meters are possible.

6.2 BOREHOLE LOGGING TECHNIQUES

The borehole logging techniques consist of remote sensing instruments lowered down a well casing or open borehole primarily to determine the geologic and hydrogeologic properties of the subsurface. Borehole logging techniques are also employed to evaluate the condition of monitoring and pumping wells. Table 6-2 presents the borehole logging tools and their respective uses. The following is a description of the borehole logging techniques that may be utilized during the facility-wide investigation.

6.2.1 Caliper Tool

The caliper tool consists of a minimum of three arms that continuously measures the diameter of the borehole or well casing. The primary use of this tool is to verify casing integrity, locate voids in boreholes, and ensure there is sufficient clearance within the borehole or casing for larger geophysical tools to be utilized.

6.2.2 Natural Gamma Tool

The natural gamma tool records natural gamma radiation emitted from the formation adjacent to the borehole. The source of the gamma radiation is the decay of naturally occurring

Table 6-2

Summary of Borehole Geophysical Techniques
Field Quality Assurance Project Plan
Facility-wide Investigation
Kenvil Works Facility, New Jersey

Geophysical Logging Method Tool	Method Objective				Method Requirements		
	Determine Well Casing Integrity	Locate Borehole Voids	Determine Stratigraphy	Determine Formation Porosity	Cased Borehole Operation	Open Borehole Operation	Fluid Filled Borehole Required
Caliper	√	√			√	√	
Natural Gamma			√		√	√	
Neutron				√	√	√	√
Single Point Resistivity		√	√			√	√
Spontaneous Potential			√			√	√
Down Hole Video	√	√	√		√	√	

radioactive elements within the formation. This tool can be used in both an open borehole and cased wells. The primary use of this tool is correlation of hydrostratigraphic units.

6.2.3 Neutron Tool

The neutron tool directly measures hydrogen saturation within the formation pore spaces by emitting high energy neutrons. This tool can be used in both open boreholes or cased wells. The primary use of this tool is to determine the porosity of the adjacent formation.

6.2.4 Single-Point Resistivity Tool

The single point resistivity tool induces an electric current that directly measures point contact resistance of the formation in Ohms. This tool can only be used in uncased boreholes with minimal cavities or washouts. The primary use of this tool is to precisely locate formation contacts.

6.2.5 Spontaneous Potential Tool

The spontaneous potential tool is similar to the single point resistivity tool with the exception that the tool measures the natural electrochemical potential between the borehole fluid and pore fluid. This tool can only be used in fluid filled uncased boreholes. The primary use of this tool, similar to single point resistivity, is to locate formation contacts.

6.2.6 Downhole Video Survey Tool

The downhole video survey tool consists of a video camera and light source to videotape borehole conditions. This tool can be used in cased and uncased boreholes, provided the drilling fluid or formation water has sufficient visibility to observe the sidewall of the formation or casing. The primary uses of this tool are to verify well integrity, identify formation horizons, and locate voids and fractures.

6.3 AQUEOUS TECHNIQUES

The primary remote sensing techniques used for aqueous scenarios include sound navigation ranging (SONAR), shallow aqueous seismic reflection, under water video and staff gauges.

SONAR is similar to seismic reflection in that energy is directed downward through the water column and is reflected back to the surface by bottom sediments or objects located on or beneath the sediment. The various SONAR methods primarily differ in the number of receivers (sonobuoys), the configuration of sonobuoys, sensitivity of sonobuoys, and number of energy sources utilized. The primary uses of SONAR will be to determine bathymetry and to locate potential explosives or explosive devices on or beneath the sediment within the major surface water bodies and to define, as best possible, the stratigraphy of the sediment.

Shallow aqueous seismic reflection provides bathymetric information as well as subsurface stratigraphic information. The typical aqueous shallow seismic reflection systems are pontoon-based rafts which are towed behind a water craft in concert with an array of linear sonobuoys.

Underwater video will provide visual confirmation of bottom surface characteristics and debris identification.

Staff gauges will be permanently installed and surveyed to North American Vertical Datum (NAVD 1988) to provide surface water elevation data.

7.0 SOIL SAMPLING METHODS

Multiple soil sampling methods may be required during the facility-wide investigation, primarily due to the large and diverse nature of the facility. Soil sampling methods consist of either mechanical (Section 7.1) or manual (Section 7.2) sampling methods. Section 7.3 describes the method-specific soil sampling procedures.

7.1 MECHANICAL SAMPLING METHODS

The following sections describe each mechanical soil sampling method. Section 7.3 describes the method-specific soil sampling procedures. Table 7-1 lists the various mechanical soil sampling methods and their respective uses.

7.1.1 Continuous Flight Hollow Stem Auger Drilling Method

The continuous flight hollow stem auger (HSA) drilling method generally utilizes a truck or all terrain vehicle to mount the drilling rig. The HSA method will be used for collecting soil samples, installing monitoring wells, and advancing Hydropunch^{TM} sampling equipment. The augers are rotated by the drilling rig, which advances the boring into the subsurface. The continuous flights of the augers extract the subsurface sediment and carry it to the surface. Center plugs are placed within the HSA to prevent the formation material from entering the hollow stem of the augers. Soil sampling is performed by removing the center plug and utilizing split spoon samplers. This method is used in unconsolidated formations and is not effective if heaving sands are encountered.

7.1.2 Tripod Drilling Method

The tripod drilling rig is a highly mobile drilling method which will be used in difficult access areas for collecting soil samples and installing monitoring wells to a maximum depth of approximately 30 feet below grade. This method utilizes an approximately 10 ft tall tripod with a pulley system centered in the middle of the three legs. A small gas powered cat-head is attached to one of the legs and is utilized to hoist equipment and a 140-pound free-fall drive hammer. Soil sampling is accomplished with split spoon samplers. In the event the borehole is expected to slough or cave-in, a 3 to 4-inch drive casing is advanced utilizing the

Table 7-1

Summary of Mechanical Sampling Methods
Field Quality Assurance Project Plan
Facility-wide Investigation
Kenvil Works Facility, New Jersey

Method Attributes	Mechanical Sampling Method							
	Continuous Flight Hollow Stem Auger	**Tripod**	**Direct Fluid Rotary**	**Air Rotary/Air Hammer**	**Odex (1)**	**Direct Push**	**Cone Penetrometer Technology**	**Test Pit (Backhoe/Trackhoe)**
Utilized in Unconsolidated Sediments	YES	YES	YES	POSSIBLE (2)	YES	YES	YES	YES
Utilized in Bedrock Formations	YES (3)	NO	POSSIBLE (4)	YES	NO	NO	NO	NO
Practical in Running Sands	NO	NO	YES	YES	YES	YES	YES	NO

Remote Operation Possible	YES	NO	YES	YES	YES	YES	YES	YES

Footnotes:

(1) Odex is used primarily for well installation.
(2) Can be utilized in unconsolidated sediments but generally requires driving temporary casing.
(3) When used in conjuction with rock corer.
(4) Can be used in weathered formations.
(5) When mounted on an all terrain vehicle.
(6) Highly fractured zones will produce large volumes of groundwater during drilling activities.

drive hammer behind the split spoon sampler to stabilize the boring. This method is used in unconsolidated formations and is not effective if heaving sands are encountered.

7.1.3 Direct Fluid Rotary Drilling Method

The direct fluid rotary drilling method (mud rotary) also utilizes trucks and all terrain vehicles to mount the drilling rig. Mud rotary methods will be used to collect soil samples and install monitoring wells where running sands are anticipated.

The mud rotary method utilizes a bit attached to drilling rods that are rotated to cut into the formation. Drilling fluid is pumped by the rig down through the drilling rods and out through ports or jets in the bit. The drilling fluid then flows upward through the annular space carrying the drill cutting to the surface. At the surface, the drilling fluid is channeled into a basin where the cuttings settle out. Clean drilling fluid is then collected at the far end of the basin and recirculated down the borehole. The drilling fluid is generally composed of water and bentonite to increase the specific gravity of the fluid. The increased specific gravity of the drilling fluid enables large volumes of formation to be lifted to the surface and prevents the borehole from caving and sloughing. The drilling fluid will also help cool the drilling bit and help prevent inadvertent ignition/detonation of potential explosive or energetic materials. In the event E&E materials are ignited/detonated, the drilling fluid will significantly reduce the force of the ignition/detonation at the surface where field personnel are located. Soil sampling is accomplished with split spoon samplers.

7.1.4 Air Rotary/Air Hammer Drilling Method

The direct air rotary drilling (air rotary) method is similar in concept to mud rotary drilling and also utilizes trucks and all terrain vehicles to mount the drilling rig. Air rotary methods will be used to collect soil samples and install monitoring wells in consolidated formations.

The air rotary drilling method utilizes a bit attached to drilling rods that are rotated to cut into the formation. High pressure air is forced down through the drilling rods and out through ports or jets in the bit by a large surface-mounted air compressor. The high pressure air then

flows upward through the annular space carrying the drill cuttings to the surface. At the surface, the drill cuttings are collected adjacent to the borehole as the air pressure drops.

The air hammer drilling method utilizes the same drilling rig as, and is often used in conjunction, with air rotary. The air hammer method uses a pneumatic hammer drill bit that rapidly strikes the bedrock while rotating. The air hammer crushes the bedrock into very fine dust that is carried to the surface by high pressure air as in the air rotary method. This method is generally slower than air rotary and primarily is utilized to drill through very resistant formations that are difficult to drill with conventional drilling bits.

The air rotary/air hammer drilling methods are generally reserved for drilling in bedrock. The high pressure air utilized to lift the drill cuttings is often insufficient to stabilize boreholes advanced through saturated unconsolidated sediments. Soil sampling is accomplished utilizing split spoon samplers.

7.1.5 Odex Drilling Method

The Odex drilling method utilizes the same drilling rig and equipment as air rotary. Odex drilling involves advancing temporary casing as the borehole penetrates the subsurface. The air rotary drilling equipment advances the borehole and carries the sediment to the surface while the temporary casing prevents the borehole from collapsing. This method is utilized in loose unconsolidated glacial till that consists of sediment too coarse for the effective use of HSA or mud rotary equipment.

The Odex drilling method will be used exclusively to install monitoring wells where the effective use of HSA or mud rotary equipment is not applicable due to loose unconsolidated glacial till. Soil sampling will not be conducted utilizing the Odex drilling method due to the equipment necessary to advance the temporary casing.

7.1.6 Direct Push Sampling Method

Geoprobe™/Earth Probe™ type direct push soil sampling methods utilize a hydraulic hammer mounted on a truck or all terrain vehicle to advance sampling devices into the subsurface. This method eliminates the need for a drilled borehole, and minimizes the

exposure to, storage and disposal of, potentially hazardous drill cuttings. This method is most appropriate for loosely compacted fine to coarse unconsolidated sediments less than 40 feet below grade. Depths greater than 40 feet and the presence of greater than sand-sized sediments and tight clays severely impact the performance of this method. Soil sampling is accomplished using large bore or macro core samplers.

7.1.7 Cone Penetrometer Technology (CPT) Method

Cone Penetrometer Technology (CPT) procedures involve directly pushing various measuring and sampling devices into the subsurface to measure lithologic and aquifer properties, and to collect soil and groundwater samples. CPT measuring and sampling devices are advanced using a hydraulic press or ram mounted on a large truck, eliminating the need for a drilled borehole, and minimizing the exposure to, and storage and disposal of, potentially hazardous drill cuttings.

The lithologic measuring device for soil and aquifer characterization is the piezocone. The piezocone is an instrument consisting of a cylindrical dutch cone penetrometer, which conforms to American Society for Testing and Materials (ASTM) D3441 standard and also has pore pressure measuring capability. The piezocone measures resistance at the cone tip concurrently with the side friction on the sleeve as the unit is advanced through the soil. The ratio of the tip resistance and side friction is displayed graphically, computed, and, based on the soil behavior, a soil classification is made (Robertson and Campanella, 1989). For example, clays typically exhibit high friction ratios, while sands generally exhibit low friction ratios. During periods when penetration is halted, a measurement of both the time for the disturbed groundwater pressure to stabilize along with the final equilibrium pressure is made. These measurements are then correlated to provide an estimate of soil permeability as well as hydrostatic pressure at measurement depth. Soil sampling is accomplished by utilizing either a Geocone™ discrete interval or split spoon sampler.

A computer on the CPT rig is used to display real-time data and to store the data on disk for further on-site use. Real-time data display facilitates operator control of the sampling. Soil

classification data, soil permeability data, aquifer characteristic data, as well as known chemical and physical properties of the contaminant, are used to determine sampling depth.

7.1.8 Test Pit Excavation Method

Test pit excavations (test pits) are generally conducted utilizing excavators such as a backhoe or track-hoe. The benefits of test pits include:

- Visual profile of the subsurface soils so that soil horizons and contamination can be better determined.
- Field sampling personnel are somewhat removed from the sampling site as intrusive activities are conducted, increasing safety in the event a detonation/ignition of E&E materials occurs.

Test pits may be chosen as an option for selected sites primarily as a safety measure during sub-surface investigations. Personnel operating the excavator will be positioned behind Lexam™ shielding to protect the operator from debris in the event an explosion occurs in the test pit. Sampling personnel will be positioned in a safe location until the test pit has been completed and it is determined that the excavation is safe to approach.

7.1.9 Remote Operation

Remote operation of the mechanical sampling devices may be required as part of facility-wide investigation due to the potential for extreme physical hazards from explosions/detonations to exist within some areas of the facility. The primary areas of the facility that may require remote operation of the sampling equipment are the NG Area, Diazo Area, PETN Area, and portions of the Development Area. The determination to employ remote operation techniques in these and other areas of the facility will be made on a case-by-case basis and will be identified in the phase-specific SAPs.

With the exception of tripod drilling, each mechanical sampling device is capable of being retrofitted to allow remote operation. The retrofitting generally involves attaching a second control panel to the primary control panel through hydraulic lines. The second control panel will have the ability to completely control the equipment. The hydraulic lines will be long enough to allow control of the sampling activity from a safe location in the event an

explosion occurs during intrusive activities. The operators will be protected by an earthen berm or sandbag bunker placed between them and the sampling activity.

In the event remote operation of equipment is required, an operation-specific health and safety addendum will be written to address each sampling location. This addendum will include a detailed description of operating procedures for equipment requiring remote operation. The addendum will be co-authored by the MWH PSO, the Hercules PSO, and the Human Factors Application (HFA) PSO. Due to the potentially extreme danger of sampling in these unique situations, no sampling will be conducted without the full understanding, planning and approval of the three PSOs.

7.2 MANUAL SAMPLING METHODS

Shallow soil samples will be manually collected with a combination of a soil coring device and bucket auger. The soil coring device will be used to collect VOC samples and the bucket auger will be used to advance the borehole and collect sample material for any additional analytical parameters. The soil coring device is a hand held tool that extracts intact soil cores from the subsurface. The bucket auger is also a hand held tool, but it does not collect intact soil cores and, therefore, is not suitable for VOC sampling. The major use of the bucket auger will be to collect the additional sample material needed for non-VOC analyses. Section 7.3 describes the specific sample handling procedures.

Note: In areas where E&E compounds are likely to be encountered, the bucket auger and soil coring device will be constructed of non-sparking, and as needed non-conductive materials, such as brass, bronze, or polyvinyl chloride (PVC).

7.3 SOIL SAMPLING PROCEDURES

The soil sampling procedures will comply with the sample selection criteria stipulated in N.J.A.C. 7:26E-3.6(a) and N.J.A.C. 7:26E-3.6(a)4. When possible soil samples will be collected in discrete 6-inch increments in compliance with N.J.A.C. 7:26E-3.6(a)5. However, in the event of poor sample recovery or a large volume of soil is required to meet analytical needs a 2-foot sample interval may be required. All exceptions to N.J.A.C 7:26E-

3.6(a), N.J.A.C. 7:26E-3.6(a)4, and N.J.A.C. 7:26E-3.6(a)5 will be noted in the field notebook and reported to the NJDEP.

The following sections describe the method-specific soil sampling procedures utilized by both the mechanical and manual sampling methods.

7.3.1 Split Spoon Sample Collection Procedures

Soil samples collected using the various drilling rigs will be collected in accordance with ASTM D1586, Standard Method for Penetration and Split-Barrel Sampling of Soils (ASTM, 1990). Samples will be collected by driving a 2-inch interior diameter split spoon sampler through unconsolidated soils ahead of the lead auger or drilling bit with a 140-pound hammer falling 30 inches until 2 feet has been penetrated or refusal is encountered. The number of hammer blows required for each 6-inch interval will be recorded by the field geologist.

7.3.2 Geoprobe™/Earth Probe™ Soil Sample Collection Procedures

Soil samples collected using the Geoprobe™/Earth Probe™ will be obtained using either a hydraulically advanced Macro Core (MC) sampler or a Large Bore (LB) sampler. The MC samplers are open tube design and measure approximately 2 inches in diameter by 44 inches long and are designed for continuous soil sample collection. If probe hole "cave-in" is significant, it may be necessary to use a closed piston assembly that fits into the MC or to switch to the LB drive point sampler. Both the closed piston assembly MC sampler and the LB sampler remain completely closed when driven to depth and are opened by releasing a stop pin from the surface. Releasing the stop pin allows a piston to retract inside of the sample tube as it is being displaced by the sample core. The LB sampler will be used when subsurface conditions prevent the use of the MC sampler or when continuous sampling is not required. The MC sampler will be advanced in 4 ft. intervals and the LB sampler will be advanced in 2 ft. intervals. To assist in the removal of the soil sample and to protect sample integrity, each of the samplers will be decontaminated and fitted with a new acetate liner prior to each use.

7.3.3 CPT Soil Sample Collection Procedures

Continuous soil samples can be collected while utilizing the CPT method by pushing a split-spoon sampler directly into the subsurface. Discrete depth sampling can also be achieved by using a Geocone™, a device that uses retractable "push plug" to allow for discrete depth sampling without requiring continuous boring or sampling. The push plug is retracted at the desired sampling depth and the sample is forced into the spoon.

The procedures for collecting soil samples for chemical analysis using these various methods are outlined below:

- Sample intervals will be selected for analyses as specified in the phase-specific SAPs.
- The sampler will be removed from the borehole, the sampler carefully opened, the sample core extruded from the sampler, and the soil visually classified. This will be accomplished by sliding the core out of the sampling device and, if necessary, cutting the acetate liner with a decontaminated stainless steel knife.
- The soil sample will then be scanned with a portable FID/PID and the results will be recorded. If a sample is collected for chemical analysis, the sample interval will be screened for E&E compounds as described in Section 5.1.
- If the sample is to be collected for chemical analysis, the soil will be placed in sample containers. Sample aliquots for VOC analysis will be collected as a grab sample following the methanol preservation procedures discussed in Section 16. Sample aliquots for all analyses except VOCs will be removed from the sampling device and placed in a decontaminated stainless steel mixing bowl or tray and thoroughly homogenized prior to transferring the sample aliquot to appropriate sample containers.
- The field geologist will prepare a boring log for each borehole. Information recorded on the boring log will include soil descriptions and classifications, as well as other pertinent data regarding the sampling event and subsurface conditions (i.e., color, apparent staining or discoloration, moisture content, presence of fill material or organic matter, etc.). Section 17 provides a detailed description of the field documentation requirements and process.

7.3.4 Soil Coring Device/Bucket Auger Soil Sample Collection Procedures

The soil coring device will be advanced by hand at each sampling prior to utilizing the bucket auger to ensure an undisturbed soil core is extracted to support VOC sample collection. The coring device and bucket auger will be advanced at 6-inch intervals and then

removed from the borehole for evaluation. The following paragraphs describe the specific soil sample collection procedures:

- Sample intervals will be selected for analyses as specified in the phase-specific SAPs.
- The soil coring device will be removed from the borehole, the sample core extruded from the sampler, the sampler carefully opened, and the soil will be visually classified.
- The sample will then be scanned with a portable FID/PID and the results will be recorded. If a sample is collected for chemical analysis, the sample interval will be screened for E&E compounds as described in Section 5.1.
- If the sample is to be collected for chemical analysis, the soil will be placed in sample containers. Sample aliquots for VOC analysis will be collected as a grab sample following the methanol preservation procedures discussed in Section 16. Sample aliquots for all analyses except VOCs will be removed from the sampling device and placed in a decontaminated stainless steel mixing bowl or tray prior to transferring the sample aliquot to appropriate sample containers.
- The bucket auger will then be used to ream the borehole and collect additional sample material for non-VOC analysis. The additional sample material collected will be placed into a decontaminated stainless steel bowl. Each 2 foot interval will be considered one sample interval and sample material from different intervals will not be mixed. Once an interval has been chosen for analysis based on VOC screening, as discussed in the previous paragraph, the sample material within the bowl will be transferred to the appropriate sample containers.
- The field geologist will prepare a boring log for each borehole. Information recorded on the boring log will include soil descriptions and classifications, as well as other pertinent data regarding the sampling event and subsurface conditions (i.e., color, apparent staining or discoloration, moisture content, presence of fill material or organic matter, etc.). Section 17 provides a detailed description of the field documentation requirements and process.

7.3.5 Test Pit Excavation Soil Sample Collection Procedures

The test pit excavations will be conducted slowly and carefully to reduce the likelihood that any drums, tanks or vessels encountered, if any, are not punctured. Geophysical techniques may be employed to locate potential drums, tanks, or vessels prior to initiating the test pit excavation. The soils and anthropogenic debris encountered during test pit excavations will be described. Photographs will be taken at each pit location and documented in the field

notebook. Additionally, readings using a FID/PID will be taken throughout the test pit operation and recorded in the field notebook.

The following paragraphs describe specific excavation, documentation, and sampling procedures:

- Sample intervals will be selected for analyses as specified in the phase-specific SAPs.
- The material removed from the test pit will be scanned with a portable FID/PID and the result recorded. If a sample is collected for chemical analysis, the sample interval will be screened for E&E compounds as described in Section 5.1.
- If the sample is to be collected for chemical analysis, the soil will be placed in sample containers. Sample aliquots for VOC analysis will be collected as a grab sample directly from the excavator bucket following the methanol preservation procedures discussed in Section 16. Sample aliquots for all analyses except VOCs will be removed from the excavator bucket and placed in a decontaminated stainless steel mixing bowl or tray and thoroughly homogenized prior to transferring the sample aliquot to appropriate sample containers.
- After the test pit excavation and sampling are completed, the excavated material will be used to backfill the test pit.
- The soils encountered within the test pit will be visually classified and photographs will be taken during and at the completion of each test pit. A log of the visual descriptions and photographs will be maintained in the field notebook. Section 17 provides a detailed description of the field documentation requirements and process.

8.0 SEDIMENT SAMPLING

Sediments will be sampled during the facility-wide investigation using mechanical and manual sediment sampling methods. This section describes the sediment sampling methods that may be utilized during facility-wide investigation.

8.1 MECHANICAL SAMPLING METHODS

Sediment samples will be collected by utilizing split spoon samplers or Vibracore™ sediment samplers. The following paragraphs describe each of these sampling methods.

8.1.1 Split Spoon

Split spoons can be utilized to collect cohesive or compact sediment that will remain within the split spoon upon retrieval from the subsurface. Split spoons are not appropriate for liquefied sediments since much of the sample will not be retained within the split spoon during retrieval from the subsurface. The split spoons will be advanced into the sediment using tripod drill rig methods described in section 7.1.2. The samples will be collected in accordance with ASTM D1586 Standard Method for Penetration and Split-Barrel Sampling of Soils (ASTM, 1990) as presented in Section 7.3.

8.1.2 Vibracore™

The Vibracore™ sediment sampling technique is the preferred mechanical sediment sampling method, where it can be safely employed, and will be used when conditions require sampling sediment at depths greater than manual sampling techniques can attain. The Vibracore™ can be mounted on a tripod or to a boat. Vibracore™ sampling will be performed by driving a 2-inch diameter aluminum sampling tube into unconsolidated sediments. Equipment designed to impart a vibrating motion to the sampling tube will be used to drive the tube into the sediment. The following procedures will be utilized for collecting soil samples for chemical analysis:

- Sample intervals will be selected for analyses as specified in the phase-specific SAPs.

- The Vibracore™ sampling tube will be removed from the borehole and carefully opened exposing the sediment core. Vibracore™ sampling tubes are generally opened with a metal saw or metal shears.
- The sample will then be scanned with a portable FID/PID and the results will be recorded. If a sample is collected for chemical analysis, the sample interval will be screened for E&E compounds as described in Section 5.1.
- If the sample is to be collected for chemical analysis, the soil will be placed in sample containers. Sample aliquots for VOC analysis will be collected as a grab sample following the methanol preservation procedures discussed in Section 16. Sample aliquots for all analyses except VOCs will be removed from the sampling device and placed in a decontaminated stainless steel mixing bowl or tray and thoroughly homogenized prior to transferring the sample aliquot to appropriate sample containers.
- The field geologist will prepare a boring log for each borehole. Information recorded on the boring log will include soil descriptions and classifications, as well as other pertinent data regarding the sampling event and subsurface conditions (i.e., color, apparent staining or discoloration, moisture content, presence of fill material or organic matter, etc.). Section 17 provides a detailed description of the documentation requirements and process.

8.1.3 Remote Sampling

Remote operation of the Vibracore™ may be required as part of the facility-wide investigations due to the potential for extreme physical hazards to exist within some areas of the facility. Section 7.1.9 describes the general procedures for remote operation of mechanical sampling equipment.

8.2 MANUAL SAMPLING METHODS

Manual sampling methods are the preferred method for collecting sediment samples and will be employed when feasible. The two primary sediment sampling techniques involve the soil coring device/bucket auger (cohesive/compact sediments) and the silver bullet sampler (liquefied sediments). The soil coring device/bucket auger and silver bullet samplers are described in Section 8.2.2.

8.2.1 Soil Coring Device/Bucket Auger

Shallow sediment samples can be collected with a soil coring device and bucket auger provided the sediment is sufficiently cohesive or competent to be held within the soil coring device and bucket auger without losing the fine grained components of the sediment. The soil coring device and bucket auger are described in Section 7.2. The sample collection and sample handling procedures are described in Section 7.3.

8.2.2 Silver Bullet

The silver bullet sampler is an aluminum alloy cylinder into which a laboratory provided clean glass collection tube is inserted. The silver bullet sampler is generally utilized to collect samples of very liquefied sediments. The top of the sampler is equipped with a T-handle which is used to push the sampler to the desired depth within the sediment. Once the desired sampling depth is reached, the sampler is rotated 360° counter clockwise filling the collection jar with sediment. The sample collection and sample handling procedures are the same as the soil coring device described in Section 7.3.

8.3 SEDIMENT SAMPLING ACCESS

Access to sediment sampling locations for both mechanical and manual sampling methods can be achieved by utilizing a small raft for large bodies of water (i.e. Duck Pond) or a temporary bridge placed over narrow stream channels. The phase-specific SAPs will identify the appropriate means of access to each sampling point.

9.0 GROUNDWATER ASSESSMENT AND MONITORING METHODS

Additional monitoring wells or non-permanent groundwater sampling points may need to be installed and sampled to complete the groundwater assessment/monitoring objectives of the facility-wide investigation. This section describes the procedures for installing, developing, measuring groundwater elevations, and purging and sampling monitoring wells, and installing and sampling non-permanent sampling points. Monitoring well certification forms will be submitted to the NJDEP for each new monitoring well installed.

9.1 MONITORING WELL INSTALLATION

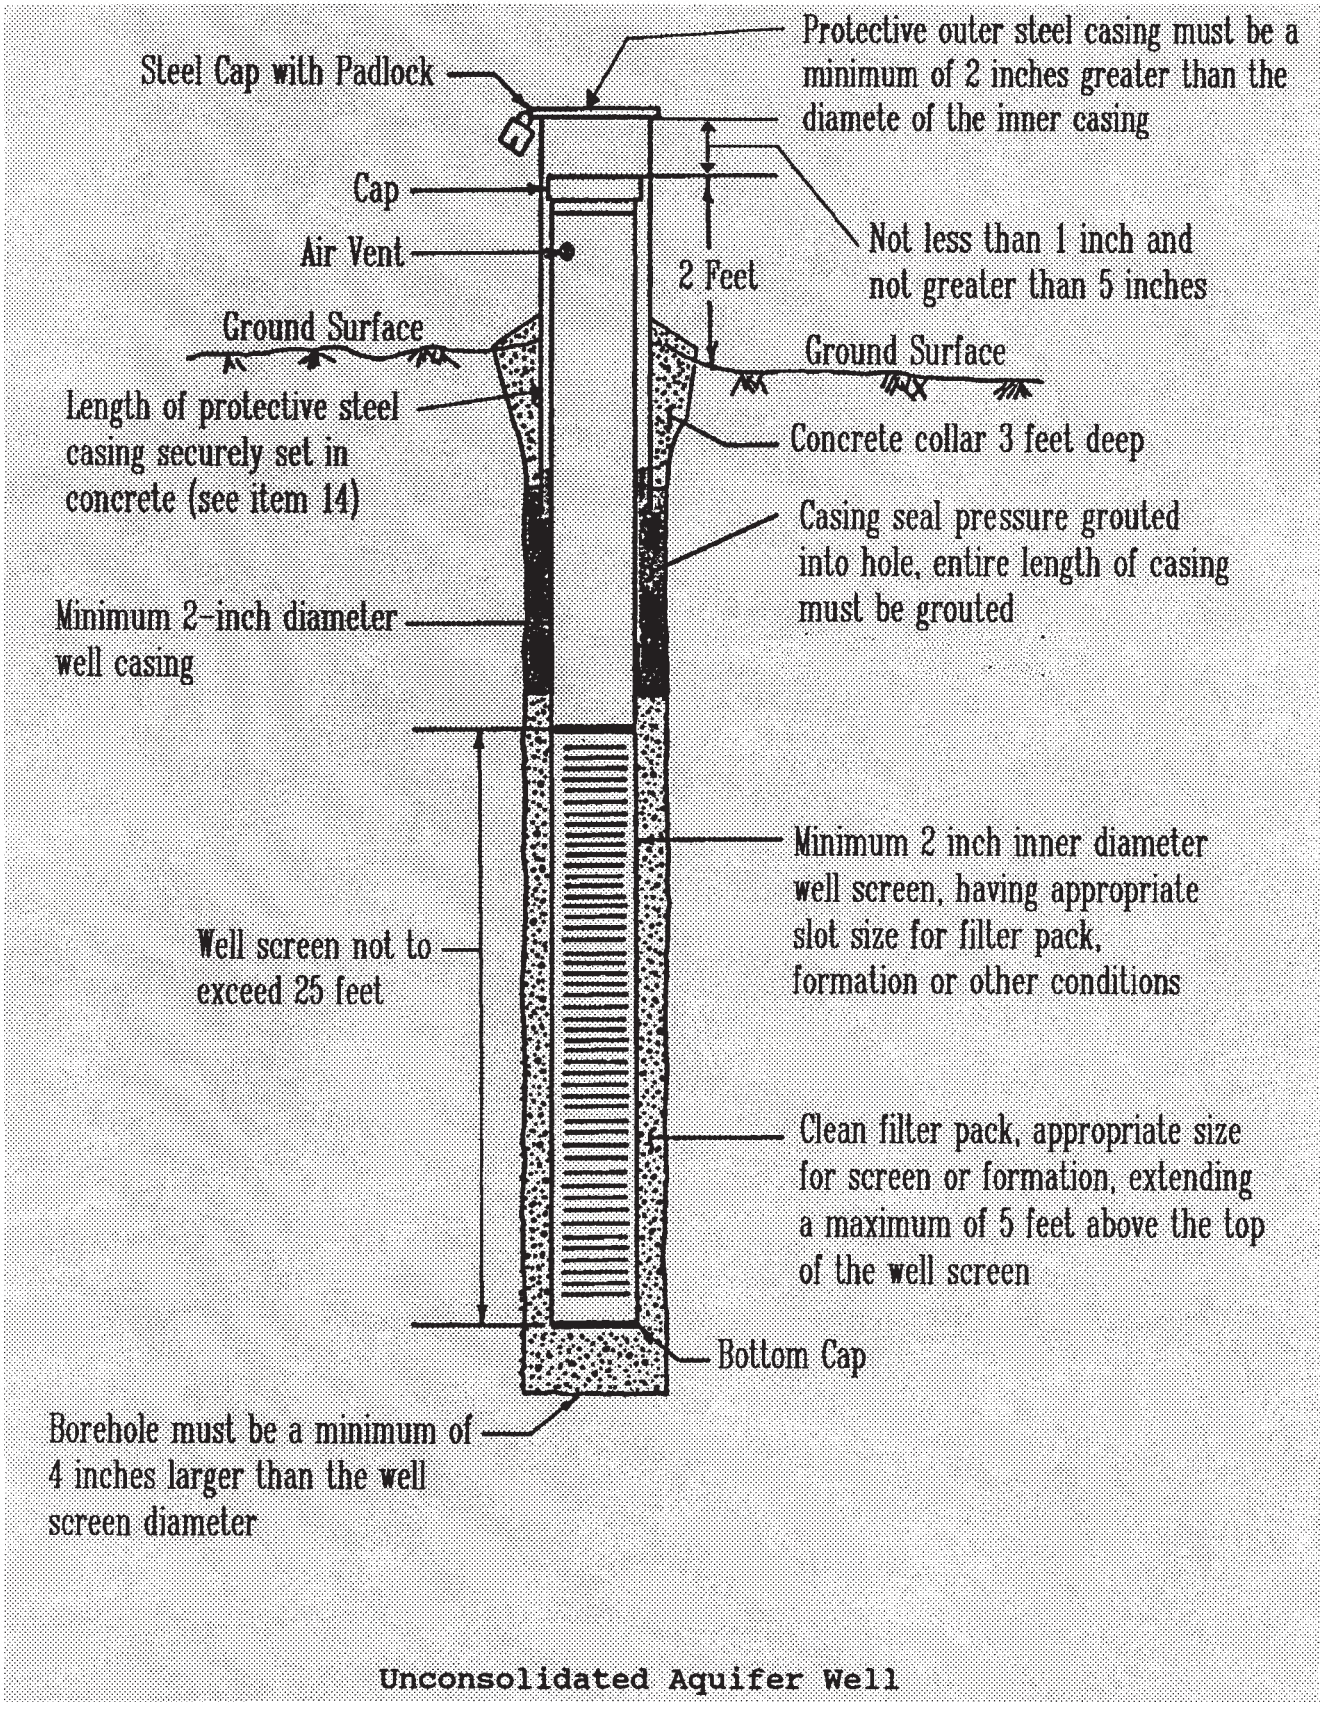
Each borehole advanced for the installation of a monitoring well will be drilled using a truck-mounted or ATV-mounted drilling rig with HSA or mud rotary capabilities. The HSA drilling method will be the preferred drilling method for installing wells less than 45 feet below grade where running sands are not expected. Mud rotary drilling will likely be employed for wells anticipated to be installed to depths greater than 45 feet, or where running sands are expected. Section 7.1 describes HSA and mud rotary drilling techniques. The following subsections describe well installation procedures for unconfined and confined wells installed in unconsolidated aquifer materials.

Note: If loose glacial till is encountered during well installation activities and the borehole cannot be kept open with the conventional drilling methods discussed in Section 7, the Odex drilling technique may be employed. The Odex drilling method is described in Section 7.1.5.

9.1.1 Unconfined Unconsolidated Aquifer Monitoring Well Installation

This section describes the specific procedures to be used for installing a monitoring well in an unconfined unconsolidated aquifer. Figure 9-1 graphically depicts an unconfined unconsolidated aquifer monitoring well. The requirements for installing a monitoring well in an unconfined unconsolidated aquifer include:

- The monitoring well will be completed according to the specifications defined in the *NJDEP Field Sampling Procedures Manual (NJDEP 1992)*. The borehole will be advanced with a minimum 6 inch outer diameter HSA or mud rotary bit.



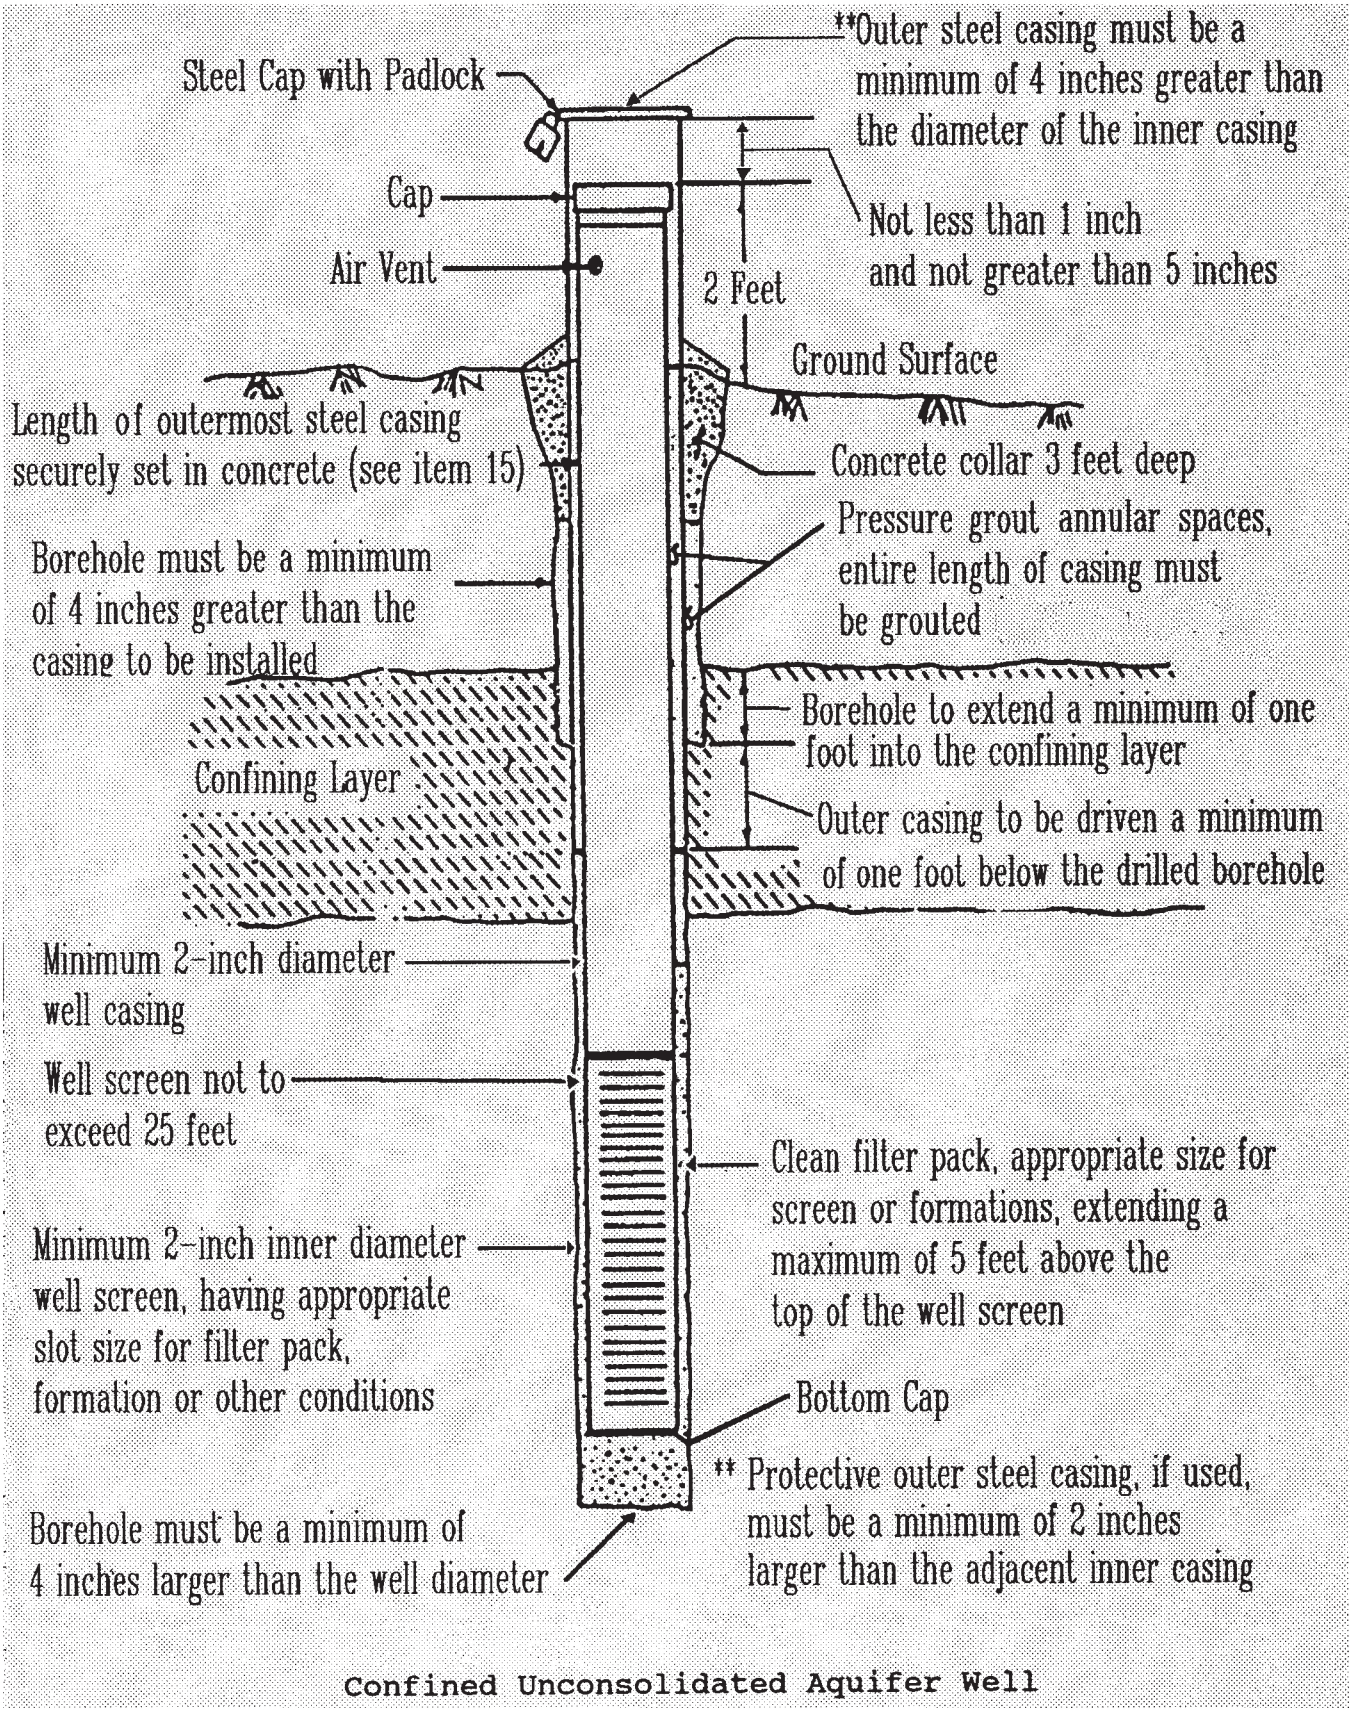
Unconsolidated Aquifer Well

HERCULES INCORPORATED FACILITY-WIDE INVESTIGATION KENVIL WORKS FACILITY, NEW JERSEY
UNCONFINED UNCONSOLIDATED AQUIFER WELL DIAGRAM
FIGURE 9-1

- Wells will be constructed of commercially fabricated, machine-slotted, threaded-flush-joint 2-inch diameter (Schedule 40) PVC well screen with an appropriate length of riser casing to extend to the ground surface. Screen slot size is anticipated to be 0.010 inch, and will not exceed 20 feet in length. However, if 0.010 inch is not appropriate for the formation a screen slot size appropriate for the formation will be selected. Screens will be fitted with a PVC bottom plug of appropriate size.
- A filter pack of clean sand of appropriate size will be placed around the screened interval. The filter pack will not extend more than 3 feet below the base of the screen or 5 feet above the top of the screen.
- A fine sand pack will be installed above the filter pack to prevent grout from infiltrating into the filter pack. The fine sand pack will extend 1 to 2 feet above the filter pack.
- The remainder of the annular space will be filled with tremie-grouted or pressure-installed cement-bentonite grout mixture to the ground surface. The blend will be proportional to mixing 94 pounds of Portland cement with 5 pounds of bentonite and 8.3 gallons of water. The cement and water will be mixed first, and then the bentonite will be added. No additives or borehole cuttings will be mixed with the seal.
- Wells will be completed with a standard 2 foot stick-up protective surface casing. A site monitoring well identification number will be affixed to each well.
- All monitoring well installation data will be recorded on a monitoring well construction summary sheet by the field geologist. The monitoring well/piezometer construction summary, presented in Section 17 will show relative depths and intervals of screen, casing, filter pack, and seals.

9.1.2 Confined Unconsolidated Aquifer Monitoring Well Installation

In the event a confining unit(s) greater than 4-feet thick is identified during the installation of an unconsolidated aquifer well, the following modifications will be made to the installation procedures. The 4-foot minimum was chosen to ensure a correct seal could be placed for the outer casing isolating the potential hydraulic connection between the two water bearing zones. It is believed that a confining unit of less than 4-feet could not be adequately sealed to prevent hydraulic connection between the two potential water bearing zones. These procedures are outlined in the *NJDEP Field Sampling Procedures Manual (NJDEP, 1992).* Figure 9-2 graphically depicts a monitoring well installed in a confined unconsolidated aquifer.



Confined Unconsolidated Aquifer Well

HERCULES INCORPORATED
FACILITY-WIDE INVESTIGATION
KENVIL WORKS FACILITY, NEW JERSEY

CONFINED UNCONSOLIDATED AQUIFER WELL DIAGRAM

FIGURE 9-2

- The borehole will be reamed to a minimum diameter of 10 inches extending at least 1 foot into the confining unit.
- A 6-inch diameter outer casing will be placed into the borehole and driven an additional 1 foot into the confining unit to isolate the upper unconfined aquifer from the lower confined aquifer.
- The outer casing will be grouted in place, and the grout will be allowed to cure for a minimum of 12 hours before additional drilling takes place.
- The well bore advancement and the monitoring well installation will continue through the outer casing according to the unconfined monitoring well installation procedures described in Section 9.1.1.

9.1.3 Monitoring Well Development

Following sufficient time for grout to cure (48 hours), each monitoring well will be developed by pumping and surging. Development will be accomplished by surging the well with a surge block and removing standing water from the well using a submersible or centrifugal pump. All equipment lowered into the monitoring well will be decontaminated as described in the Section 13 prior to mobilization to the next well.

During development, pH, specific conductance, temperature, turbidity, dissolved oxygen, and oxidation-reduction potential will be measured. Measurements will be recorded in the field notebook. Development will be continued until pH, conductivity, turbidity and temperature readings stabilized to within 10% variation and turbidity in each well stabilizes below 50 nephlometric units (NTU). Development will be limited to a maximum of 2 hours continuous pumping or 10 well volumes for a low yielding well in the event measured readings do not stabilize within 10% or turbidity remains above 50 NTUs.

9.2 WATER LEVEL MEASUREMENT

Prior to commencing well purging and groundwater sample collection, the depth to static water and depth to bottom of each monitoring well will be obtained and recorded. The depth to water measurements will be converted into a groundwater elevation and plotted on a facility map so that the groundwater flow direction can be determined.

The depth to water will be measured in each well by slowly lowering a decontaminated water level sounder accurate to the nearest 0.01 foot into the monitoring well until the sounder is activated (usually indicated by an audible tone). The water level will be determined as a depth below a marked reference point (top of well casing for stick-up wells, ground surface for flush mounted wells). Measurements will be collected at least two times at each location, or until the measurements are within +/-0.01 ft, and will be recorded in the field notebook. During gauging, MWH will also check for the presence of light and dense non-aqueous phase liquid (NAPL) using a probe specifically designed to measure NAPL/water interfaces.

9.3 MONITORING WELL SAMPLING

This section describes the specific procedures to be used to when purging and collecting groundwater samples from monitoring wells.

9.3.1 Purging

Each monitoring well will be purged prior to the collection of groundwater samples. Two methods of well purging, standard and low flow, may be utilized during well sampling activities at the facility. The standard purging method is the primary anticipated well purging method for the unconsolidated monitoring wells located on the facility. The low flow purging method may be used to reduce well purging volumes for the deeper unconsolidated water supply wells located adjacent to the facility. The following paragraph describes standard and low flow purging methods.

9.3.1.1 Standard Purging. Standard purging will be accomplished by removing a predetermined volume of standing water using either a submersible pump with new dedicated polyethylene discharge tubing, or a bailer. The volume of water removed from each well during purging will be the equivalent of three to five well casing volumes. Pumping rates will be kept as low as is reasonably possible in order to avoid pumping the well dry. If the well is pumped at a rate of 0.5 gpm or less and purged dry, no additional purging will be considered necessary and the well will be allowed to recover until a sufficient quantity of water is present in the well to collect the groundwater sample.

During purging, pH, specific conductance, temperature, dissolved oxygen, oxidation reduction potential, and turbidity will be measured by an in-line monitoring device or with external meters. These parameters will be measured at least once after each well volume has been removed. Purging will continue until the variation in each parameter is less than 10 percent over three conservative readings. If parameters do not stabilize by the time five well volumes have been removed, this will be noted and purging will be discontinued.

9.3.1.2 Low Flow Purging. Low flow purging will be performed using portable submersible or bladder pumps with dedicated Teflon^{TM}-lined polyethylene tubing. The pumps will be set at the most contaminated interval, the most permeable interval, or slightly above the midpoint of the well screen. The wells will be purged at low flow rates approximating the natural rate of inflow to the well. Depth to water measurements will be collected at least every minute after commencing purging, until the water level stabilized to less than 0.01 feet of fluctuation.

Once the water level stabilizes, pH, specific conductance, temperature, turbidity, dissolved oxygen, and oxidation-reduction potential will be measured. Purging will continue until the variation in each parameter was less than 10 percent fluctuation over three consecutive readings spaced one minute apart or until two continuous hours of purging have been completed.

Appendix G contains USEPA and NJDEP guidance documents concerning low flow groundwater sampling procedures.

9.3.2 Groundwater Sample Collection

After purging has been completed and the monitoring well has recovered to a volume sufficient for sampling, a groundwater sample will be collected for chemical analysis. The following paragraphs describe the groundwater sample collection procedures for standard and low flow purging methods.

9.3.2.1 Standard Purging Groundwater Sample Collection Methods. Groundwater samples will be collected no later than 2 hours after each monitoring well has recovered to a

volume sufficient for sampling. The 2 hour sampling limit may be exceeded if sufficient recovery volume in the well is not achieved after 2 hours of recovery; however, the sampling time should always be within 24 hours of purging.

Each groundwater sample will be collected with a new, manufacturer-decontaminated, bottom-filling, disposable bailer from the mid-water column inside the screened interval. New disposable nitrile gloves will be used when collecting groundwater samples for chemical analysis. As applicable, sample containers will be filled in the following order: VOCs, SVOCs, pesticides/PCBs, metals, and water quality parameters (e.g. hardness). All VOC containers will be filled to zero headspace.

Groundwater samples submitted for chemical analysis will be immediately placed in appropriate laboratory-supplied containers, labeled, maintained in coolers at 4°C, and delivered to an off-site laboratory for analysis using EPA-approved chain-of-custody protocols. The specific procedures for these activities are described in the AQAPP.

9.3.2.2 Low Flow Purging Groundwater Sample Collection Methods. Samples will be collected directly from the dedicated discharge tubing attached to the submersible or bladder pump. The flow rate during sampling will be the same as that used during purging. New disposable nitrile gloves will be used when collecting groundwater samples for chemical analysis. As applicable, sample containers will be filled in the following order: VOCs, SVOCs, pesticides/PCBs, metals, and water quality parameters (e.g. hardness). All VOC containers will be filled to zero headspace.

Groundwater samples submitted for chemical analysis will be immediately placed in appropriate laboratory-supplied containers, labeled, maintained in coolers at 4°C, and delivered to an off-site laboratory for analysis using EPA-approved chain-of-custody protocols. The specific procedures for these activities are described in the AQAPP.

Appendix G contains USEPA and NJDEP guidance documents concerning low flow groundwater sampling procedures.

9.4 NON-PERMANENT GROUNDWATER SAMPLING POINTS

Non-permanent groundwater sampling points are expected to be utilized during site investigation activities. The primary purpose of the non-permanent groundwater sampling points will be to quickly determine the groundwater chemistry in areas where monitoring wells are not located. Additionally, non-permanent groundwater sampling points may be employed to strategically locate new monitoring wells, in the event additional monitoring wells are necessary. Table 9-1 lists the characteristics of the non-permanent groundwater sampling points. The following sections describe installation and sample collection techniques for non-permanent groundwater sampling points.

9.4.1 Hydropunch™

The Hydropunch™ groundwater sampling system will be used in conjunction with a HSA drill rig to sample groundwater. The drill rig will advance a borehole using 4.25 inch HSA to an elevation just above the water table. The Hydropunch™ will then be advanced through and beyond the bottom of the lead auger to the desired sampling depth in the formation. Upon reaching the desired sampling depth, the outer casing of the Hydropunch™ will be retracted, exposing a polypropylene inner screen to the formation. The procedure for collecting and handling groundwater samples using Hydropunch™ sampling equipment for chemical analysis is outlined in Section 9.4.4.

9.4.2 Geoprobe ™

The Geoprobe™ groundwater sampling system may also be utilized to collect groundwater samples. The Geoprobe ™ system utilizes a screen point sampler approximately 41 inches long with a standard slot size of 0.004 inches. The sampler has O-ring seals at the drive head and an expendable drive point to provide a watertight system. A clean screen point sampler will be threaded onto the leading end of a probe rod and driven to the desired sampling interval. Once at the desired sampling interval, chase rods will be sent downhole until the leading rod contacts the bottom of the sampling screen. The Geoprobe™ tooling will then be retracted while the screen is held in place by the chase rods. As the tooling is retracted, the expendable point will be released from the sampler sheath. An O-ring at the screen head will

Table 9-1

Summary of Non-Permanent Groundwater Sampling Point Characteristics

Sample Extraction Rate Liters/Minute	.2/2 (2)	.2/2 (2)	.2/2 (2)
Mobility	Moderate/High (3)	Moderate/High (3)	Moderate
Maximum Practical Depth (feet)	<40	<40	50-100
Volume of Drilling Fluids/Cuttings Generating	Very Low	Very Low	Very Low
Remote Operation Possible	Yes	Yes	Yes

(1) Performance decreases with increase in gravel/cobble sized sediments.
(2) Two liters per minute can be achieved with a peristaltic pump for non-VOC analysis.
(3) When an all terrain vehicle (ATV) is utilized.
CPT = Cone Penetrometer Technology

maintain the seal at the top of the screen and the sampling screen will be exposed to groundwater. The procedure for collecting and handling groundwater samples for chemical analysis using Geoprobe™ sampling equipment is outlined in Section 9.4.4.

9.4.3 Cone Penetrometer Technology (CPT)

Cone Penetrometer Technology may also be utilized to collect groundwater samples. The groundwater samples are collected by advancing a CPT rod equipped with a PVC well screen to the desired sampling depth. The CPT rod is then partially withdrawn exposing the well screen to the aquifer. Groundwater samples are then collected through the CPT rod with a small Teflon ™ bailer. Additionally, the CPT can use a Hydrocone™ to collect groundwater samples. The Hydrocone™ collects samples under an inert gas (i.e. argon) back pressure to reduce turbulence through the screen and minimize volatilization of potential contaminants. The sealed Hydrocone™ is pushed to the sampling depth and opened by gas pressure. The time required to fill the sampling container is measured and soil permeability at the sampling depth can be calculated. The Hydrocone™ is resealed and raised to the surface for sample analysis preparation. The Hydrocone™ is used primarily for the collection of samples for VOC analysis.

9.4.4 Groundwater Sample Collection

The following procedures will be utilized for the collection of groundwater samples from non-permanent groundwater sampling points:

- New disposable nitrile gloves will be used when collecting groundwater samples for chemical analysis.
- An effort will be made to reduce the fines in the sample by purging the sample point for a 1-2 minutes prior to sample collection, if applicable.
- Groundwater samples will be removed from the sample probe via a small diameter Teflon™ or stainless steel bailer and new clean dedicated polyethylene rope. Non filtered samples will be transferred directly to the sample containers.
- As applicable, sample containers will be filled in the following order: VOCs, SVOCs, pesticides/PCBs, metals, and water quality parameters (e.g. hardness). All VOC containers will be filled to zero headspace.

Groundwater samples submitted for chemical analysis will be immediately placed in appropriate laboratory-supplied containers, labeled, maintained in coolers at 4°C, and delivered to an off-site laboratory for analysis using EPA-approved chain-of-custody protocols. The specific procedures for these activities are described in the AQAPP.

10.0 SURFACE WATER SAMPLING

This section describes the procedures to be utilized for surface water sampling conducted during the facility-wide investigation activities at the facility.

10.1 DISCRETE DEPTH INTERVAL SAMPLING

Discrete depth interval sampling of larger water bodies, such as Duck Pond, may be performed as part of the facility-wide investigation. Discrete depth interval samples will be collected with a weighted bottle sampler. The weighted bottle sampler consists of a glass bottle equipped with a stopper that can be remotely removed from the surface, and weights to carry the bottle to the desired sampling depth. The following is a description of the discrete depth interval sampling procedure:

- The weighted bottle sampler will be lowered to the desired sampling depth.
- The stopper will be removed from the bottle to allow it to fill with water.
- The stopper is replaced in the bottle.
- The sampler is retrieved and the collected sample is transferred to laboratory-provided sample containers.

When surface water and sediment samples are taken at the same locations, the surface water sample will be collected first to minimize turbidity and reduce the potential of contaminating the surface water sample with disturbed sediment. Where samples are collected at multiple depth intervals, the samples will be collected in descending order from shallowest to deepest. In addition, down-stream samples will be collected prior to up-stream samples.

10.2 SURFACE SAMPLING

Surface samples will be collected by slowly submerging a laboratory-provided glass sample bottle horizontally into the water at the designated sample collection point. The bottle will be gradually turned upright, keeping the lip just under the surface so that only surface water is collected. Care will be taken to minimize surface disturbance throughout the sampling process. If the water is not deep enough to turn the bottle upright, the bottle will be held at an angle as steep as possible with the lip remaining just under the surface. In the event field

personnel cannot easily access the sampling point or disturbance of the sediment is expected, the glass sample collection container will be attached to a pole of sufficient length to reach the sampling point.

10.3 SAMPLE HANDLING PROCEDURES

The following sample handling procedures will be utilized for all surface water sampling events conducted at the facility:

- New disposable nitrile gloves will be used when collecting surface water samples for chemical analysis.
- As applicable, sample containers will be filled in the following order: VOCs, SVOCs, pesticides/PCBs, metals, and water quality parameters (e.g. hardness). All VOC containers will be filled to zero headspace.

Surface water samples submitted for chemical analysis will be immediately placed in appropriate laboratory-supplied containers, labeled, maintained in coolers at 4°C, and delivered to an off-site laboratory for analysis using EPA-approved chain-of-custody protocols. The specific procedures for these activities are described in the AQAPP.

11.0 SAMPLE IDENTIFICATION

All samples collected will be designated with an alpha-numeric code that will identify each sample by the matrix sampled, site location number, sequential sample number and depth interval, as appropriate. Sampled matrices will be identified by a two-letter code, (e.g., MW for monitoring well groundwater samples). Site location number will correspond to the facility grid location and feature number (i.e. A13-2205). Sequential sample numbers at each new sampling location for each sample type will begin with 01 and will increase accordingly. Sample designations for soil and sediment samples collected will include the depth to the top of sample interval.

The following is a guide for sample identification:

Matrix	Site Location Number		Sequential Sample	Top of Sample Interval Depth in feet (if applicable)
AA	ANN-NNNN	–	NN	(NN)

where:

A = alphabetic
N = numeric

Matrix codes for this project will be as follows:

SB = Soil boring samples
SD = Sediment samples
MW = Monitoring well groundwater
GW = Groundwater samples from non-permanent sampling point
SW = Surface Water
EQ = Equipment blank
TB = Trip blank

Example sample designations are shown below:

- Soil samples collected from site I6-8125 (Development Area Research Lab) will be labeled as SB-I6-8125-01(0-2), SB-I6-8125-02(0-2), SB-I6-8125-03(0-2), etc.
- Sediment samples collected from site M6-2 (Duck Pond) will be labeled as SD-M6-2-01(0), SD-M6-2-02(0), SD-M6-2-03(0), etc.
- Surface water samples collected from site M6-2 (Duck Pond) will be labeled as SW-M6-2-01(0), SW-M6-2-02(0), SW-M6-2-03(0), etc.
- Groundwater samples collected from monitoring well MW-21 will be labeled as MW-MW-21-01.

The information contained within the sample identification will be included in the Hazsite electronic data submission.

12.0 SURVEY METHODS

Surveying is expected to be conducted using a combination of global positioning system (GPS) and traditional electronic distance measurement (EDM) equipment. Combined survey methods are necessary because communication with GPS satellites will be blocked at various locations by existing structures and physiographic features, thus requiring conventional survey methods to obtain survey data. The horizontal survey control will reference New Jersey State Plane coordinate system and the vertical survey control will reference the North American Vertical Datum (NAVD 1988).

13.0 EQUIPMENT DECONTAMINATION PROCEDURES

This section describes the equipment decontamination procedures to be used during the facility-wide investigation. All equipment used in field sampling activities will be decontaminated before and after use. Equipment used for aqueous sampling will be dedicated single use devices decontaminated by the manufacturer. If laboratory decontamination of aqueous field sampling equipment is not feasible, field decontamination will be performed at the site as outlined in this section. The Field Team Leader will ensure that appropriate decontamination procedures are followed.

13.1 HEAVY EQUIPMENT AND MOBILE SAMPLING EQUIPMENT

All heavy equipment and mobile sampling equipment used in sampling activities (i.e., excavators, drill rigs, augers, drill rods, etc.) will be decontaminated upon arrival at the site, between each subsurface sampling location, and upon leaving the site. Decontamination of this equipment will be performed at a centralized soil and debris management area (SDMA) or potentially at satellite decontamination locations. Satellite decontamination locations, if utilized, will primarily be located in isolated sections of the facility near investigation activities so that significant time is not spent mobilizing to and from a centralized SDMA.

The following procedures will be used to decontaminate heavy equipment and mobile sampling equipment:

- A decontamination pad will be constructed on-site to collect the decontamination water.
- Non-vehicular equipment (i.e. drill rods) will be staged on metal stands (off the ground).
- Equipment will be thoroughly cleaned on the decontamination pad using a high-pressure steam cleaner and potable water from an approved source.
- Decontaminated equipment will be staged in a clean location prior to use.

13.2 DIRECT PUSH SAMPLING EQUIPMENT

All direct push sampling equipment used to advance sampling equipment will be decontaminated upon arrival at the site, between each subsurface sampling location, and

upon leaving the site. Decontamination of this equipment will be performed at a centralized SDMA or potentially at satellite decontamination locations.

The following procedures will be used to decontaminate direct-push equipment:

- Equipment will be thoroughly cleaned on the decontamination pad using a high-pressure steam cleaner and potable water from an approved source. If acetate sleeves are used during sample collection, the probes may be washed with a laboratory detergent instead of steam cleaning.
- Equipment will be thoroughly rinsed with potable water.
- Equipment will be rinsed with distilled and/or deionized water.
- Decontaminated equipment will be placed in a clean location protected from fugitive dust prior to field use.

13.3 AQUEOUS AND MANUAL SAMPLING EQUIPMENT

All non-disposable manual sampling equipment (i.e. soil coring devices, sediment samplers, spoons, bowls, etc.) will be decontaminated prior to mobilization to each site and use. Decontamination of this equipment will be performed at a centralized SDMA or potentially at satellite decontamination locations.

The following procedures will be used to decontaminate the aqueous and manual sampling equipment:

- Equipment will be washed with potable water and laboratory-grade detergent.
- Equipment will be thoroughly rinsed with potable tap water.
- Equipment will be rinsed with distilled and/or deionized water from an approved potable water source.
- Equipment used to collect samples for metals analysis will be rinsed with a 10 percent solution of laboratory grade nitric acid followed by another rinse with distilled and/or deionized water.
- Equipment used to collect samples for organic analysis will be rinsed with pesticide-grade acetone rinse, air dried or pure nitrogen blow out, followed by another rinse with distilled and/or deionized water.
- Equipment will be wrapped in aluminum foil, shiny side out.
- Information concerning decontamination methodology, date, time, and personnel will be recorded in the field logbook.

13.4 FIELD MEASUREMENT AND STANDARD PURGING EQUIPMENT

All field measurement equipment (i.e., static water level indicator, pH meter, conductivity meter or submersible pump) will be decontaminated prior to each use. Decontamination of this equipment will be performed at a centralized SDMA or potentially at satellite decontamination locations.

The following procedures will be used to decontaminate the field measurement and standard purging equipment:

- Equipment will be washed with potable water and laboratory grade Alconox™ detergent.
- Submersible pumps will be cleaned with laboratory-grade detergent and tap water rinse followed by a 10 gallon flush of potable water through the pump. The pump will be placed in a decontaminated plastic drum or plastic garbage bag filled with potable water.
- Equipment will be rinsed with distilled and deionized water and allowed to air dry.

13.5 LOW FLOW PURGING EQUIPMENT

All low flow purging equipment will be decontaminated prior to each use according to the manufactures recommended procedures. Decontamination of this equipment will be performed at a centralized SDMA or potentially at satellite decontamination locations.

The following procedures will be used to decontaminate the low flow purging equipment:

- Pre-rinse. Operate pump in a deep basin containing approximately 5 to 8 gallons of potable water for 5 minutes and flush other equipment with potable water for 5 minutes.
- Wash: Operate pump in a deep basin containing approximately 5 to 8 gallons of a non-phosphate detergent solution for 5 minutes and flush other equipment with fresh detergent solution for 5 minutes. Use detergent sparingly.
- Rinse: Operate pump in a deep basin of potable water for 5 minutes and flush other equipment with potable water for 5 minutes.

- Final Rinse: Operate pump in a deep basin of distilled/deionized water to pump out 1 to 2 gallons of this final rinse water.

14.0 INVESTIGATION-DERIVED WASTE MATERIALS MANAGEMENT

This section describes handling and disposal practices for investigation-derived waste materials to be utilized during facility-wide investigation activities at the facility.

14.1 DISPOSABLE CLOTHING/EQUIPMENT

Disposable equipment and clothing with gross chemical or E&E contamination will be drummed. Drums will be labeled to identify contents and source locations. Grossly contaminated disposable equipment and clothing will be disposed of in accordance with state and federal regulations. All other disposable equipment will be disposed of as solid waste.

14.2 DRILL/SOIL CUTTINGS

Drill/soil cuttings are expected to be dispersed adjacent to the drill site. If the cuttings cannot be returned to the ground, they will be placed into 55-gallon drums. Cuttings will not be returned to the ground if they are generated in areas covered in asphalt or if the presence of contamination within the cuttings would cause a safety/health or subsequent investigation concern if returned to the ground surface. Drums, if utilized, will be labeled to identify contents and source locations. Cuttings will be disposed of in accordance with state and federal regulations.

14.3 DECONTAMINATION AND PURGE WATER

Purge water generated during well development and sampling activities will be returned to the ground surface adjacent to the well. If the purge water cannot be returned to the ground surface because of the potential for surface water runoff to surface water bodies or storm sewers, it will be contained and disposed of at the on-site Waste Water Treatment Plant (WWTP).

15.0 DUPLICATE SAMPLING PROCEDURES

This section describes the procedures to be followed when obtaining duplicate samples. Duplicate samples are to be collected for each matrix at a minimum rate of one per 20 investigative samples (5 percent of total) and will be submitted to the laboratory as "blind" samples as defined in the AQAPP.

15.1 GROUNDWATER AND SURFACE WATER DUPLICATE SAMPLE COLLECTION

Duplicate groundwater and surface water samples will be obtained by alternately filling sample containers from the same sampling device for each parameter. Samples for VOC analysis will be the first set of containers filled.

15.2 SOIL AND SEDIMENT DUPLICATE SAMPLE COLLECTION

Soil and sediment samples will be collected in 2-foot intervals. Duplicate samples for VOC analysis will be collected from the 0.5-foot interval of the core with the highest FID/PID reading. Homogenization of the remaining 1.5-foot interval of the sample for remaining parameters is necessary to generate two equally representative samples. Homogenization will be accomplished by filling a properly decontaminated stainless steel bowl with the sample and mixing it with a decontaminated stainless steel instrument. It is intended that adequate sample material be collected at one time in order to fill all the necessary sample containers. If sample material volume is not sufficient to fill all sampling containers, additional soil will be collected from within the 3-foot interval. Mixing will be continued until a consistent physical appearance is achieved. Once mixing is achieved, the sample will be divided in half and the sampling containers filled by spooning soil alternately from each half.

16.0 METHANOL-PRESERVATION SOIL SAMPLING PROCEDURES

This section describes the methanol-preservation procedures to be followed when collecting soil and sediment samples for VOC+15 analysis. Soil and sediment samples collected for VOC+15 analysis will be preserved in accordance with NJDEP's *Methodology for the Field Extraction/Preservation of Soil Samples With Methanol For Volatile Organic Compounds* (February, 1997). Samples will be collected as follows:

- A small diameter, disposable plastic syringe will be tare-weighed to 0.1 grams (g) using an electronic balance or manual scale;
- Surface soil will be trimmed from the selected sampling interval, exposing a fresh soil surface;
- A soil sample weighing between 10 g and 12 g will be collected with the syringe;
- The sample will be slowly extruded from the syringe into the laboratory-prepared sample container;
- A clean brush or towel will be used to remove any soil particles adhering to the threads on the sample container;
- The lid will be secured on the sample container, and the sample will be gently swirled to mix the soil aggregate with methanol;
- An unweighed duplicate sample, not preserved with methanol, will be collected for percent moisture determination;
- Sample containers will be placed in ziplock bags and placed in an iced cooler for delivery to the laboratory.

17.0 FIELD DOCUMENTATION

This section describes the specific field documentation procedures to be followed during facility-wide investigation activities conducted at the facility. To ensure all field documentation is permanently recorded in a legal document, any data recorded on media other than the field log book will be transposed into the field log book at the end of the days' activities.

17.1 FIELD LOG BOOK DOCUMENTATION

Field log books will provide the primary means of recording the data collection activities conducted for the facility-wide investigation. Field log books will be assigned to field personnel but will be stored in the project file when not in use. The following entries will be contained in the field log books:

Name and title of author, date and time of entry, and physical/environmental conditions encountered during field activity.

- Location of sampling or measurement activity.
- Name(s) and title(s) of field crew.
- Name(s) and title(s) of site visitors, and purpose of visit.
- Type of sampled or measured media.
- Sample collection or measurement method(s).
- Number and volume of sample(s) collected and sample containers.
- Description of sample point(s).
- Description of measuring reference points.
- Date and time of sample collection or field measurement.
- Description of sample collection equipment.
- Description of deviations from the sampling plan, if any, and reasons for the deviation.
- Sample identification number(s).
- Sample preservative, if necessary.
- Sample destination (laboratory).
- Field observation and comments.

- Description of field measurement instruments.
- Field measurement/screening data including calibration data.
- Well purge methods.
- Flow rates and duration of well purging.
- Water levels.
- Reference for maps and photographs of sampling site(s).
- Sample documentation including dates and methods of sample shipment and bottle lot numbers.
- Level of personal protection equipment being used.
- Signature of the person making the entry.

At the end of each incomplete page, a line will be drawn across the remainder of the page and initialized to indicate the end of an entry.

17.2 FIELD SAMPLING AND INVESTIGATION ACTIVITY DOCUMENTATION

Figure 17-1 presents the standard form for completion of soil boring logs in the field. A classification of each collected soil sample will be included on each boring log, as well as other descriptive data that will provide information pertinent to subsurface conditions. Each soil sample will be visually classified using American Society for Testing and Materials (ASTM) D 2488 Standard Method for Classification of Soils in the Field (ASTM, 1984) a copy of which is provided in Appendix F.

All monitoring well installation data will be recorded on a monitoring well construction summary sheet (Figure 17-2) by the field geologist. This summary sheet shows the relative depths and intervals of screen, casing, filter pack, and seals.

Groundwater purging and sampling activities will be recorded on a groundwater purging and sampling data sheet (Figure 17-3). Field sampling will be conducted in accordance with approved standard operating procedures which have been designed to preserve the in situ characteristics of the media being sampled to the extent practicable.

FIGURE 17-1

To document that the samples are representative of the environment from which they are collected, chain-of-custody records will be used as control documents to demonstrate that sample maintenance and custody are maintained. An example chain of custody record is presented in Figure 17-4. The chain-of-custody record will be initiated by the field sampling personnel upon collection of a sample, and will accompany each sample cooler. The chain-of-custody will be signed by each individual who has the samples in his/her possession.

Figure 17-5 presents daily field report form that will be completed to document personnel and equipment onsite and to detail daily field activities, progress and events of significance.

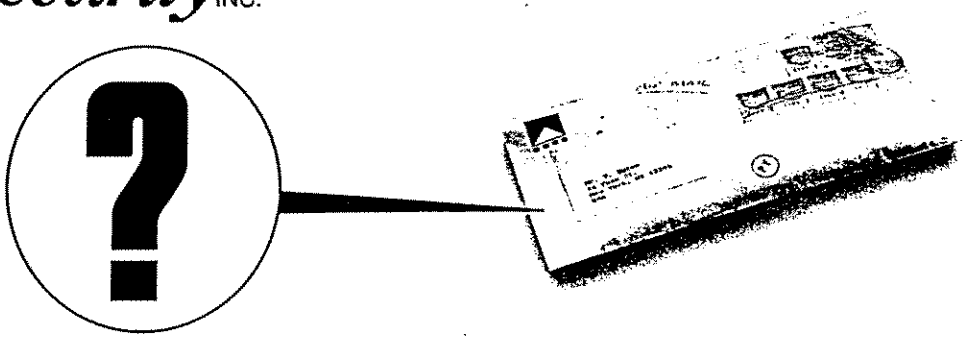
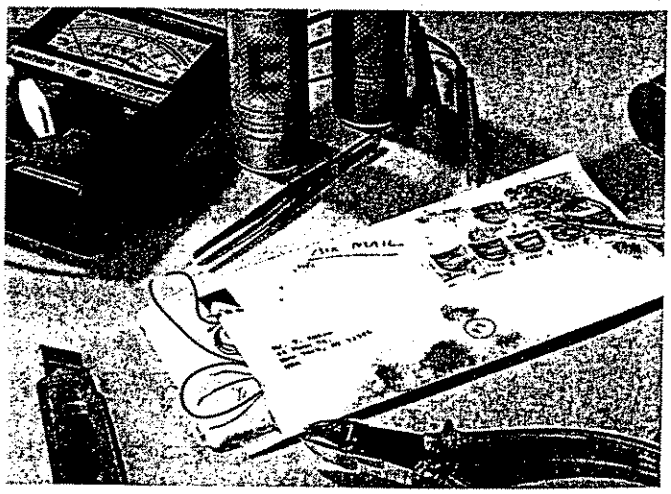
APPENDIX A
EXPRAY MANUFACTURER'S DOCUMENTATION

Mistral Security INC.



EXPRAY



Detect explosives before or after an explosion.

New: Field test kit contains three sprays, collection papers, and verification papers.

Fast and Easy: Wipe. Spray with EXPRAY. An instant color reaction indicates the presence and type of explosive, even Semtex H.

Accurate: Detects 20 nanograms of explosives.

Inexpensive: Low cost per test

Safe: No risk to you or the environment.

Spray an Answer... "On The Spot"

TECHNICAL BACKGROUND

Expray is a unique, aerosol-based field test kit for the detection and identification of Group A explosives (e.g. TNT, TNB, etc.), Group B explosives (e.g. Semtex H, RDX, C4, etc.) and compounds containing inorganic nitrates that are used in improvised explosives (e.g. ANFO). **Expray** is commonly used as a pre-blast analytical tool, post-blast investigative tool, screen against potential terrorist elements, and as a technical evaluation test in soil remediation on hazardous material "clean-up" sites. When used as a post-blast investigative tool, the product is field proven to speed up crucial investigations.

The **Expray** testing process consists of three separate test reagents;
Expray #1 (Model #1510) for Group A explosives
Expray #2 (Model #1520) for Group B explosives
Expray #3 (Model #1530) for improvised explosives containing nitrates.

Expray is a chemically cumulative testing process. First wipe the suspected surface with the collection paper (Model #530). Spray the collection paper with **Expray #1** and observe for a dark violet to brown color reaction indicating the presence of Group A explosives. Next, spray the same collection paper with **Expray #2** and observe for a pink color reaction indicating the presence of Group B explosives. Finally, spray the same collection paper with **Expray #3** and observe for a crimson pink color reaction indicating the presence of nitrate compounds. It is recommended that all three **Expray** cans be sprayed during a testing process even if a positive reaction is observed in either step #1 or #2. If the environmental surface or package being tested is light in color, the collection paper may be omitted.

The level of sensitivity (20 nanograms) surpasses that of other currently available products. The testing process is fast and efficient. No glass ampules, spatulas or waiting required. Results appear in seconds. No additional tools or equipment required. The identification/detection process requires no special training and testing can be performed "on the spot."

For both law enforcement and investigative personnel, **Expray** is a proven tool for increasing the accuracy, efficiency and number of interdictions. For forensic and environmental laboratories, it has proven to reduce the number of samples submitted for testing, saving both time and money.

Product Options:

Master kit Model #1553

Other Detection and Identification Products:

Coca-Test .....Cocaine and related narcotics
Cannabispray .....Marijuana and related narcotics
Meth-Test.....Methamphetamine and related secondary amines
Herosol.....Heroin and related narcotics
SPR Black & White.....Fingerprint detection on wet, non-porous surfaces
Nin Plus Ultra .....Fingerprint detection on porous surfaces
U.V. Trap .....Oil-based ultraviolet marking spray
Ferrotrace.....Detection of iron residues

For additional information on these as well as our full line of forensic products, including technical data, pricing information and the name of your local distributor, please contact;

APPENDIX B
DTECH MANUFACTURER'S DOCUMENTATION

IMPORTANT

Read all instructions and handling procedures before using this kit. For assistance call the TECHNICAL SERVICE HOT LINE 1-800-222-0342.

INTENDED USE

The D TECH™ TNT/RDX Soil Extraction Pac is designed to extract TNT and RDX from soil samples. This extract is analyzed using the D TECH TNT Explosives Test Kit (Item #TK-1004-1), the D TECH TNT/ RDX Screening Kit (Item #TK1001-1), or the D TECH RDX Explosives Test Kit (Item #TK-1005-1).

PRINCIPLE

Trinitrotoluene (TNT) and hexahydro-1,3,5-trinitro-1,3,5-triazine (RDX) are explosives commonly found in munitions. The presence of these compounds in soil is an indication of contamination from explosive waste residue. TNT and RDX physically bind to soil particles and must be extracted to be analyzed.

The D TECH TNT/RDX Soil Extraction Pac uses an organic solvent to extract these compounds for analysis. Following this step, the extracted compounds in the solvent are further prepared for analysis by an aqueous dilution. This enables the sample to be tested with the D TECH™ TNT Explosives Test Kit, (Item #TK-1004-1), the D TECH TNT/RDX Screening Kit (Item #TK1001-1), or the D TECH RDX Explosives Test Kit (Item #TK-1005-1).

KIT DESCRIPTION

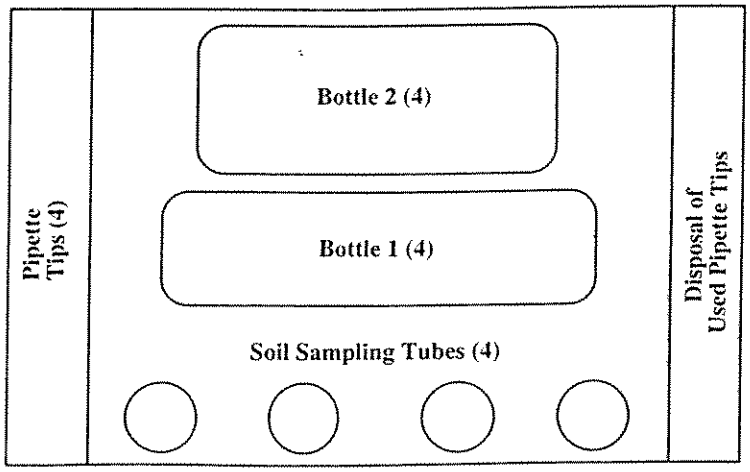
The D TECH TNT/RDX Soil Extraction Pac contains sufficient materials to perform four (4) sample extractions.

STORAGE AND STABILITY

This kit has excellent stability at room temperature and under refrigeration. For expiration dating under these conditions, see the package label.

MATERIALS PROVIDED

See tray diagram below. This diagram includes the D TECH TNT/RDX Soil Extraction Pac component names and quantity of each item.



Not shown in diagram

Used Kit Label (1)

Instruction Guide (1)

Red dot labels (4) for used Bottle 2 components.

HEALTH/SAFETY

Material Safety Data Sheets (MSDS) have been supplied with the purchase of this product. The MSDS should be read before using this test.
Included in this section. we have emphasized health and safety precautions that should be followed when handling these solutions.

PROTECT EYES WITH SAFETY GLASSES
PROTECT SKIN WITH PROTECTIVE GLOVES

Bottle 1 (50664) 100% ACETONE

Associated Hazards
Extremely Flammable Liquid and Vapor (NO SMOKING OR OPEN FLAME)
Harmful if Inhaled or Swallowed
Causes Eye Irritation

May cause damage to the central nervous system, liver, and kidneys. Chronic exposure during pregnancy may be harmful.

Symptoms of Exposure
High concentrations or prolonged exposure causes headache, dizziness, nausea, irritation of eyes and respiratory tract, narcosis and eventually unconsciousness.
Prolonged or repeated skin contact may cause irritation.

First Aid Measures
GET MEDICAL ASSISTANCE FOR ALL CASES OF OVEREXPOSURE

Skin:	Wash thoroughly with soap and water.
Eyes:	Immediately flush with water for at least 15 minutes.
Inhalation:	Remove to fresh air; give artificial respiration if breathing has stopped.
Ingestion:	If conscious, drink water and induce vomiting immediately as directed by medical personnel. Never give anything by mouth to an unconscious person.

Bottle 2 (50663) Buffer Solution

Associated Hazards
May be irritating to skin, eyes and mucous membranes.

Symptoms of Exposure
May be irritating on contact with skin, eyes or mucous membranes.

First Aid Measures
GET MEDICAL ASSISTANCE FOR ALL CASES OF OVEREXPOSURE

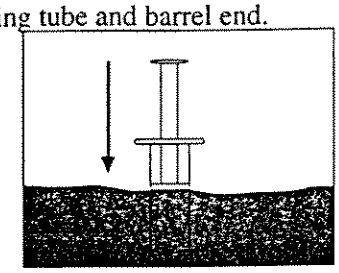
Skin:	Wash thoroughly with soap and water.
Eyes:	Immediately flush with water for at least 15 minutes.
Inhalation:	Remove to fresh air; give artificial respiration if breathing has stopped.
Ingestion:	Get immediate medical attention; if conscious, give water freely.

This package is designed to serve as a WORK STATION. At the conclusion of the test, the components can be left in the package for proper disposal.

TEST PROCEDURE

Sampling

Step 1: Break up the soil so that it is a **uniform** sample. See Sample Preparation Information (page 4) for further instructions. Draw back the **Soil Sampling Tube** plunger until it stops. Push the **Soil Sampling Tube** into the soil several times with a twisting action to firmly pack and fill the tube. Remove excess soil from external surface of the sampling tube and barrel end.



Step 2: Dispense the soil into **Bottle 1** by positioning the barrel into the neck of the bottle and firmly pushing the plunger. If soil lodges in the neck of the bottle, use the sampling tube to push it into the bottle. If soil adheres to the threads of the bottle neck and cap, wipe clean before placing cap on bottle. Cap bottle tightly.

Extraction From Soil

Step 3: Mix the soil and liquid in **Bottle 1** by **shaking** continuously over a **3 minute period**.

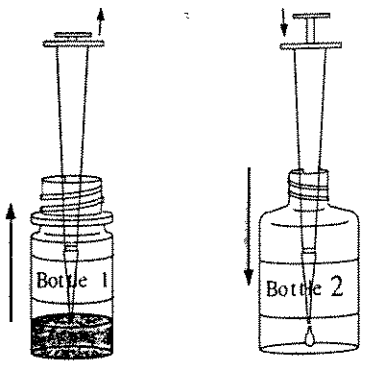
Step 4: Allow the soil to settle until a clear, liquid layer forms. Some soils will settle more slowly than others.

Diluting the Extraction Solution

Step 5: Remove cap from **Bottle 2**.

Step 6: Place an unused tip on the pipetter.

Step 7: Fully depress the plunger of the pipetter. With the plunger fully depressed, place the pipette tip into the clear, liquid layer and slowly release the plunger. Take care not to aspirate any soil.



Step 8: Dispense the contents of the pipette tip into **Bottle 2** by placing the pipette tip into the liquid and depressing the plunger. Mix **Bottle 2** thoroughly. Replace the cap tightly on **Bottle 1** and return it to the tray. Place the used pipette tip in the right side tray compartment.

Step 9: Use **Bottle 2** as a sample in Step 1 under **Test Procedure** for analysis in the D TECH TNT Explosives Test Kit (Item # TK-1004-1), the D TECH TNT/RDX Screening Kit (Item # TK1001-1), or the D TECH RDX Explosives Test Kit (Item # TK-1005-1). If the last extraction has been performed, place the "Used Kit" label on Soil Extraction Pac box to seal it shut.

Helpful Hint: Cap **Bottle 2** tightly and return it to the tray. Red dot labels have been provided to indicate used Bottle 2 components.

SAMPLE PREPARATION INFORMATION

To achieve a more homogeneous distribution and to insure reproducible test results, the soil sample should be mixed thoroughly. Remove all debris, such as sticks, stones and leaves, prior to using the D TECH **Soil Sampling Tube**. Sandy soil may require a scooping action to fill the tube. Squeezing the barrel of the Soil Sampling Tube will help to expel a tightly packed sample. Extraction of TNT and RDX is more effective if the soil plug is broken into sections during the addition to Bottle 1.

Acetone has been proven to be an efficient TNT and RDX extractant. Due to the volatile nature of acetone, bottles should be kept capped to minimize evaporation.

VOLUME SAMPLING TECHNIQUE

The D TECH TNT/RDX Soil Extraction Pac measures sample size using an efficient and economical volumetric technique. As with weight-based measurements, volumetric measurements of soils in field testing applications are not absolute and are subject to the influence of moisture content, organic matter content, soil type, etc. Variation in sample size can be minimized by insuring the **Soil Sampling Tube** is evenly filled. The sample size of the D TECH **Soil Sampling Tube** is 3 cubic centimeters, which is equivalent to an average of 4.5 grams of dry soil.

QUALITY CONTROL

All D TECH Test Kits are thoroughly quality controlled and manufactured at Strategic Diagnostics Incorporated's GMP facility. All products undergo extensive validation and field testing to assure accuracy and reliability. All products are thoroughly quality controlled to meet the published specification.

GENERAL LIMITED WARRANTY All EM SCIENCE products are warranted to meet the specifications set forth on their label only. All other warranties, expressed or implied, including the warranties of MERCHANTABILITY AND FITNESS OF USE, are excluded. Any change or modification of an EM SCIENCE product or of its prescribed procedure for use may adversely affect its stated specification.

EM SCIENCE shall not be liable in the event of any such change or modification or for any indirect or consequential damages. All EM SCIENCE products are sold on the condition that they be used and disposed of only within the scope of currently recognized critical standards related to human health and the physical environment.

Prices and specifications are subject to change without notice. We reserve the right to discontinue items without prior notice.

RDX EXPLOSIVES TEST KIT INSTRUCTION GUIDE

TK-1005-1

Phone: (800) 544-8881

IMPORTANT

Read all instructions and handling procedures before using this kit. For assistance call the TECHNICAL SERVICE HOT LINE Phone: (800) 544-8881

INTENDED USE

The D TECH™ RDX on-site and laboratory test kit is designed to provide quick, semiquantitative, and reliable test results for making environmental decisions.

The D TECH RDX Explosives Test Kit can be used on-site for identifying "hot spots", site mapping, monitoring of remediation processes and selecting site samples for laboratory analysis.

In the laboratory, the D TECH RDX Explosives Test can screen highly contaminated samples that require pre-dilution prior to instrumental analysis.

PRINCIPLE

The D TECH system for analyzing trace amounts of explosives is based on immunoassay technology.

An antibody specific for RDX compounds has been linked to solid particles which are collected on the membrane of the cup assembly.

A color developing solution added to the surface of the cup assembly develops a color inversely proportional to the concentration of RDX Equivalents in the sample (less color indicates more RDX present in sample).

RDX Equivalents are measured at parts per million (ppm) in soil and parts per billion (ppb) in water samples.

TEST KIT DESCRIPTION

The D TECH RDX Explosives Test Kit, Item #TK-1005-1, contains sufficient materials to perform four tests.

This kit can test water samples or be used with the D TECH TNT/RDX Soil Extraction Pac, Item #TK-1001S-1, to test soil samples.

The TNT/RDX Soil Extraction Pac contains only the materials needed to extract RDX from soil for semiquantitation with this D TECH RDX Explosives Test Kit. The results can be obtained by using the enclosed Color Card or the DTECHTOR Meter, Item #TK-1001M-1.

STORAGE AND STABILITY

This kit has excellent stability at room temperature and under refrigeration. For expiration dating under these conditions, see the package label.

PERFORMANCE CHARACTERISTICS

INTERPRETATION OF THE TEST The results from the D TECH RDX Explosives Test Kit can be interpreted using either the **Color Card** supplied with the kit or *the* DTECHTOR and the table provided below. If the color of the test does not exactly match a panel of the color card, user interpretation is required.

the DTECHTOR Table

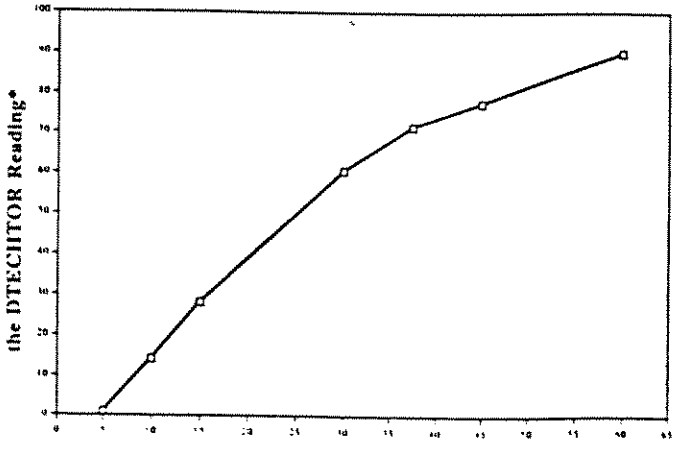
Sample	*the* DTECHTOR Reading	RDX Equivalents (ppb)
Water	LO	< 5
	1 - 30	5 - 15
	30 - 50	15 - 25
	50 - 80	25 - 45
	HI	> 45
		(ppm)
Soil	LO	< 0.5
	1 - 20	0.5 - 1.5
	20 - 45	1.5 - 2.5
	45 - 60	2.5 - 4.5
	60 - 80	4.6 - 6.0
	HI	> 6.0

SENSITIVITY The D TECH RDX Explosives Test Kit can be used to reliably measure RDX in the following ranges:

Sample	*the* DTECHTOR	Color Card
Water (ppb)	5 - 45	5 - 60
Soil (ppm)	0.5 - 6.0	0.5 - 6.0

The Minimum Detection Limit (MDL) of the test for RDX in a water sample is 5 ppb and in soil is 0.5 ppm. The graph below is a typical standard curve for the D TECH RDX Explosives Test Kit.

D TECH RDX Explosives Text Kit Standard Curve



*Percent Reflectance Relative to Reference

SPECIFICITY The D TECH RDX Explosives Test Kit has been tested for cross-reactivity with various explosives, including those found in EPA SW-846 Method 8330. The table below summarizes the cross-reactivity of these compounds in water samples using *the* DTECHTOR. A positive test result may be due to the presence of RDX, HMX or a mixture of these compounds (RDX Equivalents). Samples testing positive for RDX should be confirmed by standard methods. The D TECH RDX Explosives Test Kit has been designed to minimize the effect of environmental interferences. Sample pH, nitrate, nitrite and ammonium do not effect test results.

Compound	IC_{50}[a] (ppb)	MDL[b] (ppb)	Cross-reactivity[c]
RDX[d]	21	5	+
HMX[d]	>500	150	+
TNT[d]	>500	>500	-
Tetryl[d]	>500	>500	-
1,3,5-Trinitrobenzene	>500	>500	-
2-amino-4,6-dinitrotoluene	>500	>500	-
4-amino-2,6-dinitrotoluene	>500	>500	-
2,4-dinitrotoluene	>500	>500	-
2,6-diaminonitrotoluene	>500	>500	-
1,3-dinitrobenzene	>500	>500	-
Nitrobenzene	>500	>500	-
2-nitrotoluene	>500	>500	-
3-nitrotoluene	>500	>500	-
4-nitrotoluene	>500	>500	-
Nitroglycerin	>500	>500	-
PETN[d]	>500	>500	-

a The IC_{50} is defined as the concentration of compound required to produce a test response equivalent to 50% of the maximum response.

b The Minimum Detection Limit (MDL) is defined as the lowest concentration of compound that yields a positive test result.

c A compound is considered cross-reactive when a concentration 100 times the MDL of RDX (5 ppb) yields a positive test result.

d Chemical Names: RDX (hexahydro-1,3,5-trinitro-1,3,5-triazine), HMX(octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine), TNT (trinitrotoluene) Tetryl (methyl-2,4,6-trinitrophenylnitramine), PETN (pentaerythritol tetranitrate).

TESTING HIGHER RDX CONCENTRATIONS

RDX concentrations greater than the upper limit of the test may be determined by diluting the extract with acetone. For example, an extract from a 100 ppm soil sample, processed using the D TECH TNT/RDX Soil Extraction Pac, may be diluted 1:25 in acetone and run in the D TECH RDX Explosives Test Kit. The concentration of the undiluted sample (100 ppm) is determined by multiplying the RDX concentration of the diluted sample (4.0 ppm) by the dilution factor (25). For further information, please call our technical service hot line 1-800-222-0342.

HEALTH/SAFETY

Material Safety Data Sheets (MSDS) have been supplied with the purchase of this product. The MSDS should be read before using this test. During the execution of the test, any excess RDX is absorbed into the **Cup Assembly** absorbant plug. It is not retained on the surface of the **Cup Assembly**.
When all kit components have been used, apply the warning label to seal the box and set it aside for proper disposal. In this section, we have emphasized health and safety precautions that should be followed when handling these solutions.

PROTECT EYES WITH SAFETY GLASSES
PROTECT SKIN WITH PROTECTIVE GLOVES

Associated Hazards
May be irritating to skin, eyes, and mucous membranes.

Symptoms of Exposure
May be irritating on contact with skin, eyes, and mucous membranes.

First Aid Measures
GET MEDICAL ASSISTANCE FOR ALL CASES OF OVEREXPOSURE

Skin:	Wash thoroughly with soap and water.
Eyes:	Immediately flush with water for at least 15 minutes.
Inhalation:	Remove to fresh air; give artificial respiration if breathing has stopped.
Ingestion:	Get immediate medical attention; if conscious, give water freely.

QUALITY CONTROL

All D TECH Test Kits are thoroughly quality controlled and manufactured at Strategic Diagnostics Incorporated's GMP facility. All products undergo extensive validation and field testing to assure accuracy and reliability. All lots of product are thoroughly quality controlled to consistently meet the published specification.

APPENDIX C

DEPARTMENT OF DEFENSE PROCEDURES FOR IDENTIFYING NITROGLYCERINE, DIAZODINITROPHENOL, AND PETN

CHAPTER 12

IDENTIFICATION

12-1. General

a. Because of the use of inorganic as well as organic compounds as explosives and the presence of nitrate, nitro, nitramino, azide, diazo, and fulminic groups in these compounds, a systematic qualitative analysis of an unknown explosive is not practicable. The modern use of mixtures of explosives would render such an approach even more difficult. The identification procedures in *b* and *c* below and paragraphs 12-2 through 12-5, therefore, are based on the limited number of standard explosives and known characteristics that may be used to differentiate between these.

b. Before making any specific tests for identity, the unknown material should be examined for color, density, and particularly for sensitivity to flame, impact, and friction. The sensitivity tests may be made by subjecting a few grains of the material to the flame of a match and to impact and rubbing with a steel hammer, the material being placed on a steel block or hammer. Black powder flashes when exposed to a flame, but does not explode when struck lightly or rubbed with a hammer. Initiating explosives explode or flash when in contact with a flame and explode when struck or rubbed with a hammer. Solid noninitiating high explosives burn without explosion and are much less sensitive than the initiators to impact and friction.

c. Visual comparison of the color and crystal structure of the unknown material with the characteristics of standard explosives shown in parapraphs 7-1 through 7-29 will be of assistance in tentative identification. Should an unknown explosive be indicated to be of the sensitive type, special care should be taken in the removal of test samples, handling, and heating. Dense pressed pellets of explosive found to be, or suspected of being, of the sensitive type should be softened by soaking with water or alcohol prior to the removal of test samples.

12-2. Initiating Explosives

a. Lead Azide.

(1) Test the explosive for solubility in water. Lead azide is insoluble in water.

(2) Transfer 5 milligrams of the sample explosive to a 10-milliliter beaker and add 10 drops of a 10-percent ceric ammonium nitrate solution. A reaction accompanied with evolution of nitrogen gas is indicative of the presence of azide.

(3) Treat the solution of the sample obtained in (2) above with a few drops of a 10-percent solution of potassium dichromate. A yellow to reddish-yellow precipitate is indicative of the presence of lead.

(4) Transfer 2 milligrams of the sample to a 5-milliliter beaker. Add 5 ml of a 10-percent solution of ferric chloride solution. A red color is formed, which disappears slowly when a few milliliters of dilute mercuric chloride solution are added. This confirms that the explosive is lead azide.

b. Mercury Fulminate.

(1) Test the explosive for solubility in water. Mercury fulminate is insoluble in water.

(2) Transfer 10 milligrams of the sample explosive to a fritted glass crucible of medium porosity. Extract the sample with a 20-percent solution of

sodium thiosulfate, catching the washings in a 50-milliliter beaker containing 10 drops of a 1-percent phenolphthalein indicator solution. When the mercury fulminate is treated with sodium thiosulfate, it hydrolyzes with formation of alkali (NaOH), which changes the color of the indicator solution from colorless to red.

$$Hg(CNO)_2 + 2Na_2S_2O_3 + 2H_2O \rightarrow HgS_2O_3 + C_2N_2 + 4NaOH$$

(3) Transfer 10 milligrams of the sample to a 10-milliliter beaker and add 3 drops of concentrated hydrochloric acid solution and 2 milliliters of water. Transfer the solution to another beaker containing 1 drop of a 5-percent solution of potassium iodide. The formation of a bright red precipitate indicates the presence of the mercuric ion.

c. Diazodinitrophenol (DDNP). Dissolve 0.05 gram of the low-density greenish-yellow to brown explosive in acetone. Upon adding a larger volume of ice water, the explosive should appear as a bright yellow precipitate. Prepare a saturated solution of the explosive in 200 milliliters of water. Add to this 5 milliliters of a 20-percent solution of sodium hydroxide and mix. The evolution of a colorless gas and the appearance of a reddish-brown color in the solution indicate the explosive to be diazodinitrophenol.

d. Lead Styphnate. Wet 0.1 gram of the heavy light orange to reddish-brown material with 10 milliliters of water and then add slowly 10 milliliters of a 20-percent solution of ammonium acetate. Agitate the mixture until solution is complete. Add 10 milliliters of a 10-percent solution of potassium dichromate. The appearance of a bright yellow precipitate indicates the presence of lead. To 0.1 gram of the explosive in a beaker add 10 milliliters of a 10-percent solution of hydrochloric acid. Heat the mixture in a steambath and evaporate to dryness. Cool the beaker and contents and add 10 milliliters of ether. Mix the contents and allow to settle. Decant or filter off the ether solution and evaporate this to dryness at ordinary temperature. Dissolve the residue in 25 milliliters of water and add 0.1 gram of solid potassium cyanide. The absence of color indicates the explosive to be lead styphnate. Other tests will be included in revised specification JAN-L-757.

e. Tetracene. Wet 0.25 gram of the fluffy pale yellow explosive with 5 milliliters of a 10-percent solution of sodium hydroxide and warm the mixture in a steambath until solution is complete. Note if there is an odor of ammonia. Cool the solution and add 1 milliliter of a 5-percent solution of copper acetate. The appearance of a bright blue precipitate indicates the explosive to be tetracene. If 0.25 gram of the unknown explosive is not available, the identification could be carried out microscopically. See CWS Field Tab Manual 1-3-14 and MDRC Report on Microscopic Identification of Primers.

12-3. Noninitiating High Explosives

a. Many noninitiating high explosives can be identified by making a series of tests and comparing the results with those given in table 12-1. The tests are as indicated in (1) through (4) below.

(1) *Test 1.* Place 0.05 gram of the explosive in a 5-milliliter beaker, add 2 to 3 milliliters of distilled water and stir for 5 minutes.

(*a*) Observe color of liquid.

(*b*) Wet one end of a strip of Universal pH indicator paper and note any change in color.

(*c*) Add a drop of Nessler's reagent and note the color of any precipitate formed. Prepare the reagent by dissolving 5 grams of potassium iodide in a minimum quantity of cold distilled water and adding a saturated aqueous solution of mercuric iodide until a faint precipitate is formed. Add 40 milliliters of 50-percent potassium hydroxide solution. After the solution has

clarified by settling, dilute to 100 milliliters with distilled water, allow to settle and decant.

(2) *Test 2.* Place 0.05 gram of the unknown material in an indenture of a white porcelain spot-test plate. Add two or three drops of a 65- to 68-percent aqueous solution of ethylenediamine and stir. Note the color of the solution (not the solid).

(3) *Test 3.* Place 0.05 gram of the unknown material in an indenture of a white porcelain spot-test plate and add three or four drops of a diphenylamine solution. Stir the mixture and, after 1 minute, note the color of the solution. Prepare the diphenylamine solution by dissolving 1 gram of diphenylamine in 100 milliliters of concentrated CP sulfuric acid.

Table 12-1. Tests of Noninitiating Explosives

	Water solution or extract			Color effect of test with—		
	Color	Color of universal pH test	Color of PPT with Nessler's	Ethylenediamine	Diphenylamine	Thymol
TNT	(Insoluble)			Maroon	Colorless	
Tetryl	(Insoluble)			Red	Blue	Green.
Picric acid	Yellow	Red	(No ppt)	Orange		
Explosive "D"	Yellow		Brown	Orange		
Haleite	None		(No ppt)	None	Blue [1]	Orange.
Nitroguanidine	None		White		Blue	Green.
Ammonium nitrate	None		Brown	None	Dirty green	Green.[1]
PETN	(Insoluble)			None	Dirty green	Green.
Nitroglycerin	None		(No ppt)		Deep blue	Green.
DEGN	None		(No ppt)		Deep blue	Brown.[1]
Nitrocellulose	None				Blue	Green.
Tritonal	(Insoluble)			Maroon	Colorless	
Tetrytol	(Insoluble)		(No ppt)	Maroon	Intense blue	Green.
Picratol	Yellow		Brown	Maroon		
Ednatol	None	Orange	(No ppt)	Maroon	Intense blue	Orange.
Amatol	None		Brown	Maroon	Dirty green	Green.
Ammonal	None		Brown	Maroon	Dirty green	Green.
Pentolite	None		(No ppt)	Maroon	Dirty green	Green.
Trimonite	Yellow	Red	(No ppt)	Orange	Red	
Tridite	Yellow	Red	(No ppt)	Orange		
Black powder [2]	None	No change			Blue	Green.

[1] Color appears immediately.
[2] Sometimes explodes mildly (puffs) upon addition of sulfuric acid.
[3] Tests of dried water extract.

(4) *Test 4.* Place 0.05 gram of the unknown material in an indenture of a white porcelain spot test plate. Add an equal amount of crystalline thymol and three drops of concentrated sulfuric acid. Stir the mixture and note its color after 5 minutes or more.

b. If the unknown material is not identified completely by the tests and data in paragraphs 12-1 and 12-2 and *a* above, tests should be made to determine whether it is one of those indicated in (1) through (8) below.

(1) *RDX.* Place 1 milligram of the white, unknown material in an indenture of a white porcelain spot-test plate and add not more than 1 milligram of thymol. Grind and mix the two intimately with the end of a glass stirring rod. Add three drops of concentrated sulfuric acid and stir. After 1 minute, add two drops of CP 95 percent ethanol, and stir the mixture. The appearance of a pink or rose color indicates the presence of RDX. If a blank test is made, a faint pink color is developed, but the effect of the presence of RDX is unmistakable.

(2) *Composition* A-3. Place 0.1 gram of the material in a 10-milliliter beaker and add two or three drops of acetone. Warm the mixture and allow to stand for 5 minutes. Evaporate the acetone by gently warming on a steambath, cool and add 2 milliliter of carbon tetrachloride. Cover the beaker and warm the contents, occasionally swirling the mixture. Cool the mixture and allow the undissolved material to settle. Decant the supernatant liquid into a 5-milliliter beaker, evaporate to dryness, note if a waxy (not tarry) residue is obtained. Dry the undissolved material in the 10-milliliter beaker and test for RDX as described in (1) above.

(3) *Composition B.* Place 0.2 gram of the pale yellow to medium brown material in a 10-milliliter beaker and add 2 to 3 milliliters of chloroform. Cover the beaker. Warm and digest the mixture for 10 minutes with occasional swirling. Decant the supernatant liquid through a paper filter and evaporate the filtrate to dryness. Digest the insoluble residue in the beaker with three more portions of chloroform, discarding the decanted liquid in each case. Dry the insoluble residue by evaporating any adherent chloroform. If the original material was composition B, the residue from the chloroform solution consists of TNT and wax. Test the TNT and wax mixture with ethylenediamine and diphenylamine as described in *a*(2) and (3) above. The insoluble residue obtained by extraction with chloroform consists of RDX. Test it as described in (1) above.

(4) *Composition C-3.* Place 0.2 gram of the putty-like explosive in a 10-milliliter beaker and add 5 milliliters of benzene. Mix and digest for 10 minutes, crushing any lumps present. Decant the supernatant liquid the benzene with gentle heating. Note through a paper filter and evaporate whether a dark, tarry residue remains. Wash the insoluble residue left by benzene extraction with two or three 3-milliliter portions of a 2:1 ether-ethanol mixture and dry the washed residue. Test this as described under RDX ((1) above). To the decanted ether-ethanol washings, add 15 milliliters of distilled water and heat the mixture until all ether and alcohol are removed. Note if there is separated a white precipitate, which is nitrocellulose. Catch the precipitate on a filter, wash with ethanol, dry by evaporation of the ethanol, and test for nitrocellulose as described in *a* above.

(5) *Torpex.* Place 0.2 gram of the explosive in a 5-milliliter beaker and extract with three 3-milliliter portions of acetone. Dry the insoluble residue and examine this under a microscope. Note if it has the characteristic appearance of metallic aluminum. Place 0.2 gram of the explosive in a 5-milliliter beaker and digest with two 3-milliliter portions of benzene, decanting the benzene into a small evaporating dish. Evaporate the benzene solution to dryness and test for TNT as described in *a* above. Dry the insoluble residue from the benzene extraction and test for RDX as described in (1) above.

(6) *Tritonal.* Place 0.2 gram of the explosive in a 10-milliliter beaker and add 5 milliliters of acetone. Stir, allow any undissolved material to settle, and decant the liquid. Wash the insoluble matter with two 5-milliliter portions of acetone, dry and examine under a microscope. Note if it has the characteristic appearance of metallic aluminum. Subject the explosive to the tests prescribed for TNT in *a* above.

(7) *Amatol.* Place 0.2 gram of the yellow

material in a 5-milliliter beaker, add 3 milliliters of distilled water, and stir for 5 minutes. Decant the liquid through a filter and evaporate to dryness. Test the dried solid as prescribed for ammonium nitrate. Dry the water-insoluble residue and test as prescribed for TNT in *a* above.

(5) *Aluminum.* Place 0.2 gram of the explosive in a 5-milliliter beaker and digest with 3 milliliters of distilled water. Decant the liquid through a filter and evaporate to dryness. Test the dried solid as prescribed for ammonium nitrate in *a* above. Digest the insoluble residue in the beaker with three 3-milliliter portions of acetone, decanting these through a filter. Dry the insoluble residue and examine under a microscope. Note if it has the characteristic appearance of metallic aluminum. Evaporate the filtrate to dryness by warming gently. Test the dried solid as prescribed for TNT in *a* above.

12–4. Black Powder

Place 0.2 gram of the black material in a 5-milliliter beaker, add 2 to 3 milliliters of distilled water, and stir for 5 minutes. Decant the liquid through a filter and catch the filtrate in a beaker. Evaporate this to dryness and subject the dried white solid to the tests shown in table 12–1. Dry the water-insoluble residue in the beaker, cool, and digest with two 5-milliliter portions of carbon disulfide, decanting these into an evaporating dish. Evaporate the carbon disulfide solution to dryness at room temperature. By means of a [illegible] examine the yellow residue [illegible] the insoluble black residue for metallic [illegible] carbon disulfide extraction. Note if they have the characteristic appearances of sulfur crystals and charcoal, respectively.

12–5. Propellents

Since the standard propellents are complex mixtures of nonexplosive as well as explosive compounds, and the separation of these compounds is rendered difficult by their dispersal in colloided nitrocellulose, simple identification tests for the various compositions are not practicable. Qualitative analysis of an unidentified propellent composition requires numerous solvent extractions, fractionation of the extracts, and tedious identification of the individual ingredients so isolated. The security classification of many of the standard compositions puts their identification outside the scope of this manual. The reader is referred to the applicable specifications for descriptions of the procedures involved in the analysis of such compositions.

Product Profile

PCB RaPID Assay®

General Description

Polychlorinated biphenyls (PCBs) were marketed under the trade name Aroclor® from 1930 to 1977 for use in transformers, capacitors, printing inks, paints, pesticides and many other applications. The Toxic Substances Control Act (TOSCA, 1976), declared PCBs to be toxic and carcinogenic and banned manufacture.

PCBs are classified by the US EPA as Group B2 contaminants, a probable human carcinogen based on sufficient evidence in animals and inadequate data in human studies (US EPA, 1991). PCBs do not readily degrade in the environment and tend to bioaccumulate. The EPA has set a Maximum Contaminant Level for PCB in drinking water of 0.5 ppb and various levels in soil.

Current EPA-approved methods for the detection of PCBs are costly and require lengthy sample preparation, large volume extraction and solvent exchange. The PCB RaPID Assay® eliminates the need for clean-up steps and GC/ECD instrumentation.

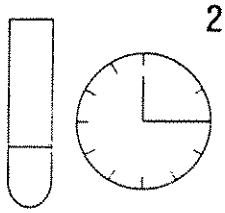
The PCB RaPID Assay applies the principles of enzyme linked immunosorbent assay (ELISA) to the determination of PCBs. ELISAs use selective antibodies which are attached to solid supports, in combination with sensitive enzyme reactions. The immunochemical reaction provides high selectivity due to the extraordinary discriminatory capabilities of antibodies. The powerful catalytic ability of the enzyme provides highly sensitive detection. These features produce an analytical system capable of detecting very low levels of chemicals.

Features

Rapid	–	60 results in less than 45 minutes.
Precise	–	within and between assay %CV <5% at 4.4 ppb.
Accurate	–	highly selective immunochemical method.
Efficient	–	rapid results can cut costs by allowing better personnel and equipment utilization.
Sensitive	–	least detectable dose in water of 0.2 ppb as Aroclor 1254 (90% B/Bo).
Test Range	–	water: 0.5 to 10.0 ppb as Aroclor 1254. soil: 0.5 to 10.00 ppm.

PCB RaPID Assay® — Assay Protocol

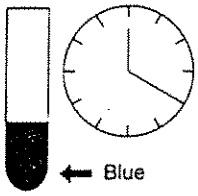
1. Add 200 µL of prepared sample, 250 µL enzyme conjugate, and 500 µL antibody coupled magnetic particles.



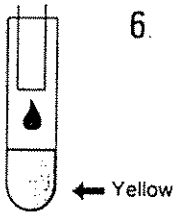
2. Incubate for 15 minutes.

3. Using the RaPID magnetic separator, decant, wash and vortex (2x).

4. Add 500 µL color reagent.



5. Incubate 20 minutes. Blue color develops.



6. Stop the reaction an read color at 450 nm Solution turns yellow

Performance

Specificity

The proprietary antibody used in this assay was developed to detect PCBs. The cross-reactivity with different Aroclors can be expressed as the least detectable dose (LDD) which is estimated at 90% B/B0.

Compound	LDD Water (ppb)	LDD Soil (ppm)	50% B/Bo Water (ppb)	50% B/Bo Soil (ppm)
Aroclor 1254	0.20	0.50	3.60	3.60
Aroclor 1260	0.20	0.30	2.30	2.30
Aroclor 1248	0.22	0.42	4.22	4.22
Aroclor 1242	0.34	0.80	8.80	8.80
Aroclor 1262	0.36	0.64	4.74	4.74
Aroclor 1232	0.84	2.24	18.76	18.76
Aroclor 1268	0.92	2.30	21.80	21.80
Aroclor 1016	0.94	2.70	25.60	25.60
Aroclor 1221	13.54	26.60	162.60	162.60

Precision

Water samples were fortified with Aroclor 1254 at different levels and assayed in singlicate five times over five days. The following results were obtained (n=25):

Sample #	1	2	3	4
Mean	0.86	3.10	4.36	8.04
% CV [a]	8.5	6.2	4.6	4.9
% CV [b]	15.7	6.1	0.6	2.5

[a] within assay [b] between assay

Recovery

Four water samples, taken from a small creek, local pond, well and municipal water source were fortified with various levels of Aroclor 1254 and assayed with this system. The following results were obtained (n=12):

Spike (ppb)	Recovery Mean ± S.D.	%
1.0	0.86 ± 0.08	86
3.0	3.18 ± 0.28	106
4.0	4.32 ± 0.36	108
8.0	7.68 ± 0.66	96
Average		99

Solvent Tolerances

The following solvents do not interfere with this assay when their concentration in the sample is at, or lower, than those listed.

Solvent	Maximum Conc. Tolerated
Acetone	5%
Acetonitrile	2%
DMF	5%
Methanol	10%
Methylene Chloride	0.2%

Results

When using the RPA-I RaPID Analyzer™, results are reported in ppb PCB. If read in a standard spectrophotometer, results from the calibrators are plotted on graph pape and used to determine final results. It is recommended that a control be included in each run. A positive control (3.0 ppb) is supplied with the PCB RaPID® Assay kit.

As with any analytical technique (GC, HPLC, etc.), positive results requiring some action should be confirmed by an alternate technology.

Product Profile

Carcinogenic PAHs RaPID Assay®

General Description

Polynuclear or polycyclic aromatic hydrocarbons (PAHs) are a group of compounds composed of two or more fused rings. The U.S. EPA has identified 16 unsubstituted PAHs as priority pollutants. Some of the four, five and six- ring PAHs are considered to be probable or possible human carcinogens. The seven (7) PAHs that are typically considered to be probable or possible human carcinogens are benzo[a]anthracene, chrysene, benzo[b]-fluoranthene, benzo[k]fluoranthene, benzo[a]pyrene, indeno[1,2,3-cd]pyrene, dibenzo[a,h]anthracene. Benzo[a]pyrene is the most potent carcinogen among PAHs. PAHs are introduced into the environment as a product of natural and fossil fuel combustion.

As a source of environmental contamination, PAHs are a serious problem at manufactured gas plants (MGP), coking operations, wood preserving sites that use creosote as a preservative and petrochemical waste disposal sites. The large number of these sites which are contaminated by PAHs in soil and groundwater has led to federal and state agencies to mandate their clean-up. Under certain circumstances site remediation can be based on carcinogenic PAH levels and site risk assessment is usually based on the carcinogenic PAH contamination. The federal and state agencies have set various regulatory levels for PAHs in soil, however the usual concentrations of interest are below 1 ppm for individual carcinogenic PAHs.

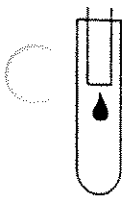
The current EPA-approved methods for the detection of PAHs are costly and require lengthy sample preparation, and large volume extraction. The Carcinogenic PAHs RaPID Assay® eliminates the need for clean-up steps and GC/MS or HPLC instrumentation.

The Carcinogenic PAHs Assay applies the principles of enzyme linked immunosorbent assay (ELISA) to the determination of Carcinogenic PAHs. ELISAs use selective antibodies attached to solid supports in combination with sensitive enzyme reactions. The immunochemical reaction provides high selectivity due to the extraordinary discriminatory capabilities of antibodies. The powerful catalytic ability of the enzyme provides highly sensitive detection. These features produce an analytical system capable of detecting very low levels of chemicals.

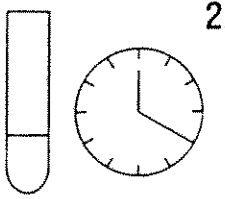
Features

Rapid	–	50 results in 60 minutes after sample preparation.
Precise	–	within and between assay %CV <10% at 1, 5 and 10 ppb in water.
Accurate	–	highly selective immunochemical method.
Efficient	–	rapid results can cut costs by allowing better personnel and equipment utilization.
Sensitive	–	least detectable dose in soil of 10 ppb as Benzo[a]pyrene.
Test Range	–	Water: 0.2 ppb to 10 ppb as Benzo[a]pyrene. soil: 10 ppb to 500 ppb as Benzo[a]pyrene.

Carcinogenic PAHs RaPID Assay® — Assay Protocol



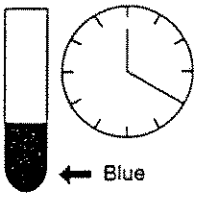
1. Add 200 µL of prepared sample, 250 µL enzyme conjugate, and 500 µL antibody coupled magnetic particles. Vortex.



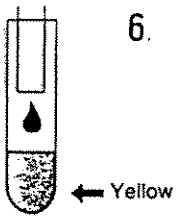
2. Incubate for 20 minutes.

3. Using the RaPID Magnetic Separator, decant and wash.

4. Add 500 µL color solution.



5. Incubate 20 minutes.



6. Stop the reaction and read color at 450 nm.

Performance Carcinogenic PAHs

Specificity

The cross-reactivity of the Carcinogenic PAHs RaPID Assay for various polynuclear aromatic hydrocarbons and petroleum products can be expressed as the least detectable dose (LDD) which is estimated at 90% B/B_0, or as the dose required to displace 50% (50% B/B_0).

Compound	LDD Water (ppb)	LDD Soil (ppb)	50% B/B_0 Water (ppb)	50% B/B_0 Soil (ppb)

Product Profile

PAHs RaPID Assay®

General Description

Polynuclear or polycyclic aromatic hydrocarbons (PAHs) are a group of compounds composed of two or more fused rings. The U.S. EPA has identified 16 unsubstituted PAHs as priority pollutants.

Some of the four, five and six-ring PAHs such as chrysene, benzo[a]pryene and indeno[1,2,3-c,d]pryene are considered to be probable or possible human carcinogens. Benzo[a]pyrene is the most potent carcinogen among PAHs. The two and three-ring PAHs, such as naphthalene, anthracene and phenanthrene, are noncarcinogenic and are found as a component of certain grades of fossil fuels. They are referred to as the fuel PAHs. PAHs are introduced into the environment as a product of natural and fossil fuel combustion.

As a source of environmental contamination, PAHs are a serious problem at manufactured gas plants (MGP), coking operations, wood preserving sites that use creosote and petrochemical waste disposal sites. They are also commonly found in fuel products such as heating oil, diesel fuel and No. 6 fuel oil. The large number of these sites contaminated by PAHs in soil and groundwater has led federal and state agencies to mandate their clean-up. These agencies have set various regulatory levels for PAHs in soil, however, the usual concentrations of interest are 1 ppm to 10 ppm.

The current EPA-approved methods for the detection of PAHs are costly and require lengthy sample preparation, and large volume extraction. The PAHs RaPID Assay® eliminates the need for clean-up steps and GC/MS or HPLC instrumentation.

The PAHs RaPID Assay applies the principles of enzyme linked immunosorbent assay (ELISA) to the determination of PAHs. ELISAs use selective antibodies attached to solid supports in combination with sensitive enzyme reactions. The immunochemical reaction provides high selectivity due to the extraordinary discriminatory capabilities of antibodies. The powerful catalytic ability of the enzyme provides highly sensitive detection. These features produce an analytical system capable of detecting very low levels of chemicals.

Features

Rapid – 50 results in 60 minutes after sample preparation.

Precise – within and between assay %CV <15% at 5.10, 20 and 40 ppb.

Accurate – highly selective immunochemical method.

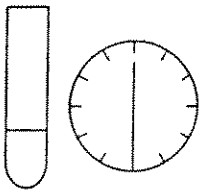
Efficient – rapid results can cut costs by allowing better personnel and equipment utilization.

Sensitive – least detectable dose in soil of 70 ppb as Phenanthrene (90% B/Bo).

Test Range – assay: 0.7 to 50.0 ppb as Phenanthrene; soil: 70 ppb to 5.0 ppm as Phenanthrene.

PAHs RaPID Assay® — Assay Protocol

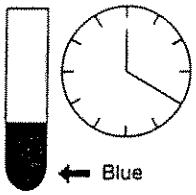
1. Add 250 µL of prepared sample, 250 µL enzyme conjugate, and 500 µL antibody coupled magnetic particles. Vortex.



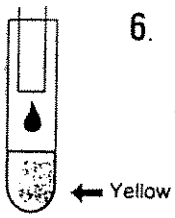
2. Incubate for 30 minutes.

3. Using the RaPID Magnetic Separator, decant, wash and vortex (2x).

4. Add 500 µL color solution.



5. Incubate 20 minutes. Blue color develops.



6. Stop the reaction and read color at 450 nm. Solution turns yellow.

Performance PAHs

Specificity

The cross reactivity of the PAHs RaPID Assay for various polynuclear aromatic hydrocarbons and petroleum products can be expressed as the least detectable dose (LDD) which is estimated at 90% B/Bo, or as the dose required to displace 50% (50% B/Bo).

Compound	LDD Water (ppb)	LDD Soil (ppm)	50% B/Bo Water (ppb)	50% B/Bo Soil (ppm)

1.0 SCOPE AND APPLICATION

The following Standard Operating Procedure (SOP) describes the procedures that will be utilized to operate the Innov-X Systems X-Ray Fluorescence (XRF Analyzer) Spectrometer for field analysis of metals in soils and sediments. This SOP complies with the requirements of New Jersey Administrative Code (N.J.A.C.) 7:18 "Regulations Governing the Certification of Laboratories and Environmental Measurements".

- This method describes the field procedures to be utilized to perform in-situ soil/sediment analysis, bagged soil/sediment sample analysis, and prepared soil/sediment sample analysis.
- This SOP is in accordance with EPA Method 6200: Field Portable X-Ray Fluorescence Spectrometry for the Determination of Elemental Concentrations in Soil and Sediment.
- This SOP will be used in conjunction with the Innov-X XRF Instruction Manual, included in Appendix A.
- Individuals who have been trained to operate a XRF Analyzer or who are under the direction of a trained individual will only use this method.

1.1 CONSTITUENTS OF INTEREST

Constituents of interest identified in this SOP were determined based on the results of laboratory analysis performed during site investigation activities conducted at the Hercules Kenvil Works Facility. Each of the following constituents were detected at a concentration greater than or equal to the corresponding applicable soil and/or sediment criteria/standard. These include the following:

- Antimony,
- Arsenic,
- Cadmium,
- Chromium,
- Copper,
- Lead,
- Mercury,

- Nickel,
- Selenium,
- Silver,
- Thallium, and
- Zinc

Table 1 presents soil/sediment detection limits (in ppm) and concentration ranges that are applicable, utilizing the XRF Analyzer, for each constituent of interest and other various elements utilizing a testing time of 2 minutes (Refer to Section 5.0).

2.0 SUMMARY OF METHOD

The following is a brief summary of the XRF method.

- XRF is used to identify metal constituents in the subsurface and quantify the amount of those metal constituents present.

- An element is identified by its characteristic X-ray emission wavelength or energy. High-energy X-ray photons are emitted from a source (X-ray tube) and strike the sample, knocking electrons out of the innermost orbitals. When this occurs, the atoms become ions and are unstable. The electrons will move from the outer orbit to the inner orbital space, emitting energy referred to as a secondary X-ray photon (fluorescence). This secondary X-ray produced is characteristic of a specific element. The energy of the emitted fluorescence X-ray photon is determined by the difference in energies between the initial and final orbits of the individual transitions. Wavelengths are inversely proportional to the energies and are specific for each element. The intensity (number of element-specific characteristics produced in a sample over a time frame) is measured to provide quantitative results (i.e. parts per million (ppm)) of a given element in a sample.

- The XRF Analyzer is equipped with Light Element Analysis Program (LEAP) capabilities. LEAP provides the lowest possible detection limits for elements lighter than iron. Elements such as Chromium produce lower energy x-rays than other elements. These lower energy x-rays are not as effectively excited by standard conditions. LEAP modifies the x-ray tube beam conditions to settings with are optimized for the detection of elements lighter than iron.

- XRF Analyzer does not destroy the sample aliquot.

3.0 SUPPLIES AND EQUIPMENT

The following is a list of supplies and equipment necessary to operate and run the XRF Analyzer.

- XRF Analyzer with attached Compaq iPAQ (iPAQ) Pocket PC® handheld computer (data logger).
- Lithium ion batteries
- Battery Charger and AC Adapter
- Standardization Cap – used to standardize XRF Analyzer
- IPAQ cradle and AC adapter
- Testing stand – benchtop-docking station for the analyzer.
- Stainless steel bowls and spoons – to homogenize samples
- Soil moisture probe – to determine moisture content in samples
- Mortar and pestle: glass, agate, or aluminum oxide – to grind samples
- 0.25 mm sieve: stainless steel, nylon, or equivalent – to prepare samples
- 250 um mesh sieve: stainless steel, nylon, or equivalent – to prepare samples
- Drying oven: convection or toaster oven - to minimize moisture content in samples
- Polyethylene sample cups: 31 to 40 mm in diameter with collar or equivalent
- Polyethylene film: 2.5 to 6.0 um thick – to cover sample cups and prepare samples
- Containers: glass or plastic – to store samples
- Plastic bags – collection and homogenization of samples

4.0 POSSIBLE INTERFERENCES

The following potential interferences can exist when utilizing XRF technology. All attempts will be made to reduce potential interferences as much as possible.

4.1 ELEMENTAL OVERLAP

- Interference may occur when the spectral peak from one element overlaps either partially or completely with the spectral peak of another element. If the XRF Analyzer is calibrated for both elements the extent of the interference can be handled. The element being interfered with may be measured with a poorer detection limit or poorer precision. If the XRF Analyzer is not calibrated for the interfering element, then the XRF may report the presence of elements not in the sample or greatly elevated concentrations of elements in or not in the sample. Calibration Verification (discussed in detail in Section 6.0) utilizes reference standards which are generally applicable for Antimony, Arsenic, Barium, Cadmium, Chromium, Copper, Lead, Mercury, Nickel, Selenium, Silver, Thallium, Tin, and Zinc to reduce the likelihood of elemental overlap. In the event of elemental overlap, the XRF Analyzer has a built-in program which mathematically separates the overlapping peaks. The intensities of each element are corrected by using Compton Normalization (Refer to Section 6.0)

4.2 SAMPLE REPRESENTATIVENESS

- Non-representative (inorganic (rocks) and organic (root material)) sample matter may decrease sample representativeness. All non-representative matter will be removed from the sample to ensure sample representativeness.

- Moisture content in the sample aliquot may decrease sample representativeness. Samples will be dried and homogenized to ensure sample representativeness for samples selected for definitive data (prepared samples).

- Inconsistent positioning of samples if front of the probe window may decrease the X-ray signal as the distance from the radioactive source increases. The window of the probe will be in direct contact with the sample.

4.3 MATRIX EFFECTS

- Physical matrix effects may result from variations in the physical character of the sample. These variations may include particle size, uniformity, and homogeneity. Samples will be homogenized to decrease potential matrix effects for samples selected for definitive data (prepared samples).

- Moisture content in the sample aliquot may increase potential matrix effects. Soil moisture will be determined by utilizing a soil moisture probe. If moisture content is greater than 20%, samples will be dried prior to being homogenized to reduce potential matrix effects for samples selected for definitive data (prepared samples).

4.4 MOISTURE EFFECTS

- Moisture content greater than 20% may alter the soil/sediment chemistry. Soil moisture will be determined by utilizing a soil moisture probe. If moisture content is greater than 20%, samples will be dried prior to being homogenized to reduce potential matrix effects for samples selected for definitive data (prepared samples).

- Moisture content may impede the ability to properly prepare a sample. It is difficult to grind and sieve a sample with high moisture content. Soil moisture will be determined by utilizing a soil moisture probe. If moisture content is greater than 20%, samples will be dried prior to being homogenized to reduce potential matrix effects for samples selected for definitive data (prepared samples).

4.5 AMBIENT TEMPERATURE CHANGES

- Ambient temperature changes can affect the gain of the amplifiers producing instrument drift. The XRF Analyzer has a built-in automatic gain control, which makes periodic adjustments to compensate for the influence of temperature changes on its energy scale. If extreme temperature changes occur, the XRF Analyzer will prompt the user to re-standardize (Refer to Section 5.0) the instrument in order to make the necessary adjustments.

- Samples collected for definitive data (prepared samples) will be analyzed indoors under controlled temperatures.

5.0 OPERATION OF XRF

The following is the start up and analysis procedures for the Innov-X Systems Model X XRF Analyzer. The manufacture's instruction manual is included as Appendix A.

5.1 START UP PROCEDURE

- Connect the battery charger to an 110V-240V AC power source. Place one of the Lithium ion batteries on the charge and charge for at least 2 hours. Charge the second battery.

- Charge the iPAQ using the attached AC adapter for at least 30 minutes.

- Install the fully charged battery into the XRF Analyzer.

- Press the On/Off button on the base of the pistol grip of the analyzer and the power button on the iPAQ.

- The **Main Menu** will appear upon start up.

- Select the **SOIL** analysis mode. The Analysis Screen will appear. The instrument will undergo a one-minute hardware initialization period.

- Standardize the instrument by placing the standardization piece (316 Stainless Steel mask) on the front of the instrument. Select the gray box in the center of the screen or select **File-Standardize** to begin from the window. During standardization, a red light will blink on the top of the instrument indicating the X-ray tube is energized and the shutter is open. An amber light on the back of the instrument will illuminate and a status bar will appear, tracking the progress of the measurement. When standardization is complete, a message stating "**Successful Standardization**" will appear and display the resolution of the instrument.

  - Standardization should be performed any time the analyzer hardware is initiated or restarted and should be repeated approximately every 4 hours or as directed by the display. The spectrum collected from the 316 Stainless Steel Mask is compared to values stored from when the instrument was calibrated at the factory. If there are any problems with the instrument, they will be indicated by an error message.

- Select **OPTIONS** mode to activate LEAP, select **LEAP Settings** from the **SOIL** analysis screen. Select **Sequential Testing. Standard followed by Light Element**.

- Select **OPTIONS** mode, **Set Testing Times**. A screen will appear prompting the user to enter a Minimum and Maximum Testing Time. Enter 2 minutes. Depending on desired accuracy of results, sample time may be increased. If this

option is chosen, live update results will not be displayed during analysis. If a test is stopped before the minimum testing time has elapsed, the test will be aborted and no results will be calculated.

5.2 ANALYSIS PROCEDURE

- Place sample over display window of XRF Analyzer.

- Pull trigger or press **START** on the iPAQ screen to begin the test. A red light will blink on the top of the instrument indicating X-rays are being emitted. The screen will display the words "**Test in Progress**", the time elapsed, and the words "**Waiting for Data**". The word "**Testing**" will blink on and off in the low right hand corner of the screen.

- After 2 minutes have elapsed, as indicated by the user by the set test time option, the **RESULTS** screen will open and final results will be displayed on the screen. Each line of the results display will show the name of the element, its calculated concentration (in ppm), and the error on the measurement (error will decrease with increased testing time). Non-detected elements are also shown as less than the calculated limit of detection for each element for that test.

- All result concentrations will be calculated on a dry weight basis utilizing the following equation:

  – Dry Weight = Result concentration / (1-% moisture)

- All results will be recorded and archived electronically.

6.0 CALIBRATION

The following presents calibration procedures.

- The XRF Analyzer is calibrated at the factory, generally based on the Compton Normalization method. The XRF Analyzer uses the measured intensity of each element's fluorescence from each sample and the calibration data to produce elemental concentrations. Additional on-site calibration is not necessary because the user checks the calibration as part of quality control efforts.

- The XRF Analyzer is calibrated at the factory with LEAP beam conditions. Additional on-site calibration is not necessary because the user checks the calibration as part of quality control efforts.

- Calibration verification will be performed any time the analyzer hardware is initiated or restarted and will be repeated approximately every 4 hours or as directed by the display. The spectrum collected from the 316 Stainless Steel Mask is compared to values stored from when the instrument was calibrated at the factory. If there are any problems with the instrument, they will be indicated by an error message. Calibration Verification utilizes reference standards which are generally applicable for Antimony, Arsenic, Barium, Cadmium, Chromium, Copper, Lead, Mercury, Nickel, Selenium, Silver, Thallium, Tin, and Zinc.

- An energy calibration check is performed automatically during the standardization check. If there are any problems with the instrument, they will be indicated by an error message.

- All relevant calibration information will be recorded and archived electronically.

7.0 QUALITY ASSURANCE AND QUALITY CONTROL

All relevant quality assurance and quality control information will be recorded and archived electronically. All quality assurance and quality control (QA/QC) samples will be prepared following the procedures described in Section 8.0.

7.1 INSTRUMENT BLANK

- A SiO_2 blank (provided by manufacturer) will be utilized to perform instrument blank analysis for insitu, bagged, and prepared samples (Refer to Section 8.0). The instrument blank will be analyzed once per every 20 samples. The SiO_2 blank will be tested to ensure that there are no reported contaminant metals on the XRF Analyzer window. If testing does not identify metals at detectable concentrations, no contaminant metals are present on the XRF Analyzer window. If testing identifies metals at detectable concentrations, the user will thoroughly clean the XRF Analyzer window and retest the instrument blank. The user will repeat the above steps as necessary until no metals are identified at detectable concentrations.

7.2 METHOD BLANK

- A SiO_2 blank (provided by manufacturer) will be utilized to perform method blank analysis for prepared samples only (Refer to Section 8.0). A method blank will be collected for every 20 prepared samples. Method blanks are tested to verify that cross contamination has not occurred. If testing of the blank identifies metals at detectable concentrations, cross contamination may occur. All equipment will be cleaned thoroughly to remove any possible contamination. The user will repeat the above steps as necessary until no metals are identified at detectable concentrations.

7.3 CALIBRATION VERIFICATION

- The manufacturer provided NIST standard reference samples for calibration checks by the user. The NIST standard will be analyzed for approximately 2 minutes. This test will be performed upon instrument start up and one per every 20 samples. The difference between the XRF result for an element and the value of the standard should be 20% or less.

7.4 PRECISION VERIFICATION

- One precision sample will be analyzed per day by conducting 7 to 10 replicate measurements of the sample. Precision is assessed by calculating a relative standard deviation (RSD) of the replicate measurements for the analyte. The RSD values should be less than 20% for most analytes, except chromium, for which the value should be less than 30 percent.

7.5 CONFIRMATORY SAMPLES & ACCURACY VERIFICATION

- A confirmatory sample will be analyzed once per every 10 prepared samples. The confirmatory sample will be collected from the same sample material that is analyzed on–site.

8.0 SAMPLE COLLECTION

The following procedures will be utilized for sample collection.

8.1 PREPARED SAMPLE COLLECTION

Prepared samples will be collected in the field and analyzed at the XRF field laboratory. Prepared samples will be utilized to provide definitive data for site investigation/remediation activities. Figure X visually presents the procedures that will be utilized to prepare a sample. All sample equipment will be thoroughly decontaminated prior to and in between sample collection.

- A sample aliquot of 50-100 grams will be collected.
- Sample will be homogenized in stainless steel bowls.
- Moisture content in each sample will be determined with a soil moisture probe.
- If soil moisture is greater than 20%, the sample will be dried in a convection oven to reduce moisture content.
- Sample will be placed in a 60 mesh sieve to homogenize the sample.
- The remaining sample will be ground in a mortar in pestle to homogenize the sample.
- If necessary, sample will be placed in a 250 um mesh sieve to completely homogenize the sample.
- Sample will be placed in 5-10 gram polyethylene sample cups and covered with 2.5-6.0 um thick polyethylene film. Sample cups will contain at least 0.5 inches of sample aliquot.
- Sample will be placed on the testing stand, completely covering the window.
- Sample will be tested using the XRF Analyzer.
- If confirmatory sample is collected, a sub sample will be submitted for laboratory analysis.

8.2 BAGGED SAMPLE ANALYSIS

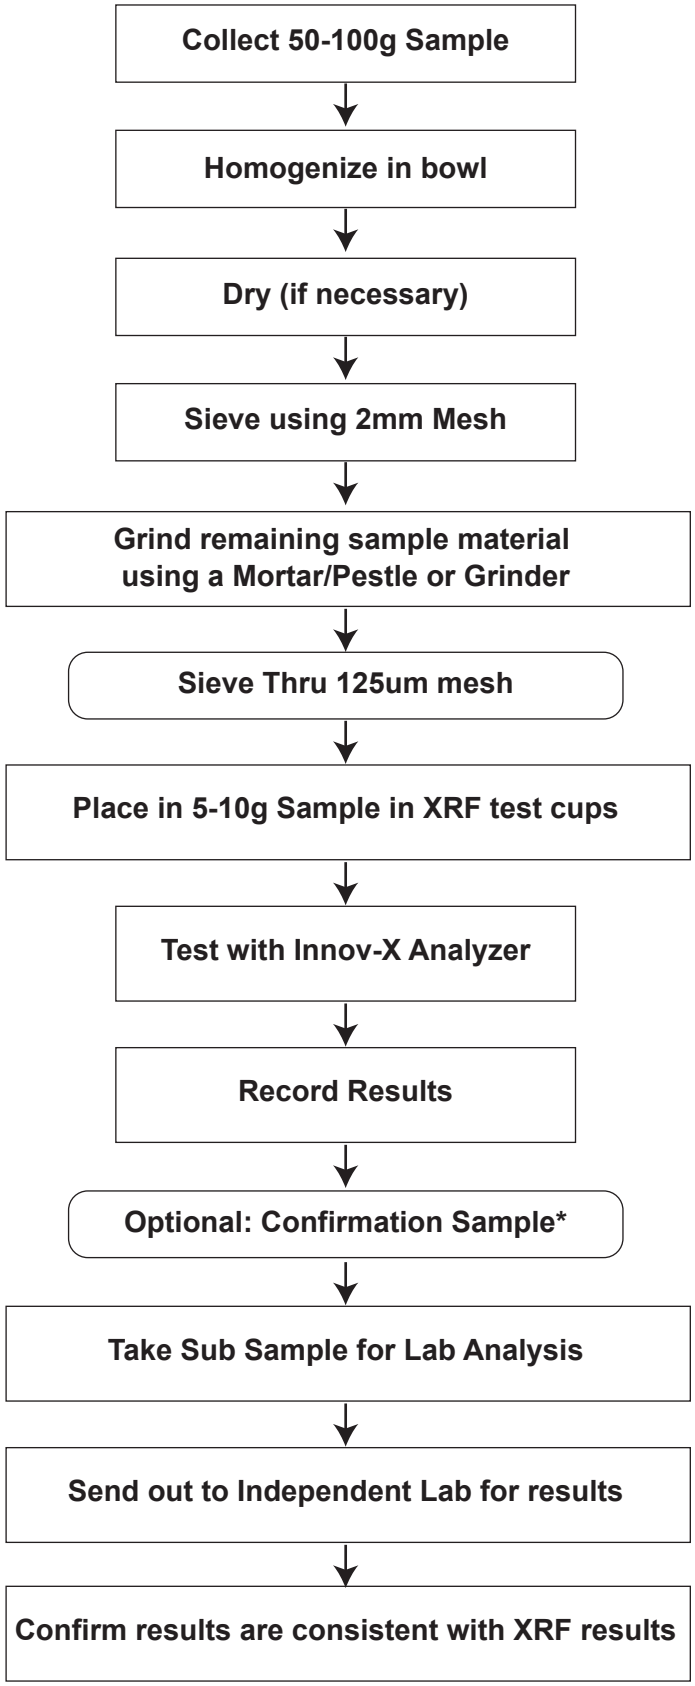
- Non-representative matter (inorganic (rocks) and organic (root material)) will be removed from the sample and the sample will be homogenized. The sample aliquot will be placed in a new plastic bag and placed on top of the testing stand, completely covering the window. Sample bags will contain at least 0.5 inches of sample aliquot. Sample will be tested using the XRF Analyzer.

- This analysis is not intended to produce definitive results. This analysis will be used to support definitive results, provide screening results, and determine if additional actions are warranted.

8.3 INSITU ANALYSIS

- Performed by pointing the analyzer at the ground with the front of the probe head flush with ground surface. Sample will be tested using the XRF Analyzer. The XRF Analyzer window will be cleaned after each analysis. Possible interferences will be eliminated as much as possible prior to analysis.

- This analysis is not intended to produce definitive results. This analysis will be used to support definitive results, provide screening results, and determine if additional actions are warranted.



* *A confirmatory sample will be analyzed once per every 10 prepared samples.*

KENVIL, NEW JERSEY

PREPARED SAMPLE COLLECTION PROCEDURE

MWH

FIGURE 1

Table 1

Method Detection Limits
XRF SOP
Kenvil Works Facility
Kenvil, New Jersey

Element	Symbol	Detection Limit (ppm)	Comment
Antimony	Sb	120	Constituent of interest
Arsenic	As	10	Constituent of interest
Barium	Ba	100	
Cadmium	Cd	50	Constituent of interest
Calcium	Ca	1,000	
Chlrorine	Cl	2,000	
Chromium	Cr	40	Constituent of interest
Cobalt	Co	200	
Copper	Cu	30	Constituent of interest
Lead	Pb	16	Constituent of interest
Manganese	Mn	89	
Mercury	Hg	14	Constituent of interest
Molybdenum	Mo	10	
Nickel	Ni	40	Constituent of interest
Phosphorus	P	2,500	
Potassium	K	1,500	
Rubidium	Rb	11	
Selenium	Se	9	Constituent of interest
Silver	Ag	120	Constituent of interest
Strontium	Sr	13	
Sulphur	Symbol	2,500	
Thallium	Tl	16	Constituent of interest
Tin	Sn	100	
Titanium	Ti	150	
Uranium	U	20	
Vanadium	V	50	
Zinc	Zn	30	Constituent of interest
Zirconium	Zr	10	

Maximum Concentration Range = 20,000 to 30,000 ppm
XRF Analyzer can measure higher concentrations but with poorer accuracy
as its outside the linear response range of the Compton Normalization method
Detection Limts are valid with 2 minute tests.

Chapter 1 Introduction

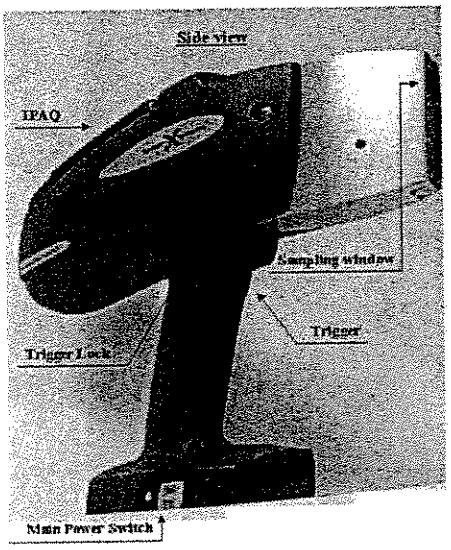
1.0 INSPECTING YOUR INNOV-X ANALYZER

Upon receipt:

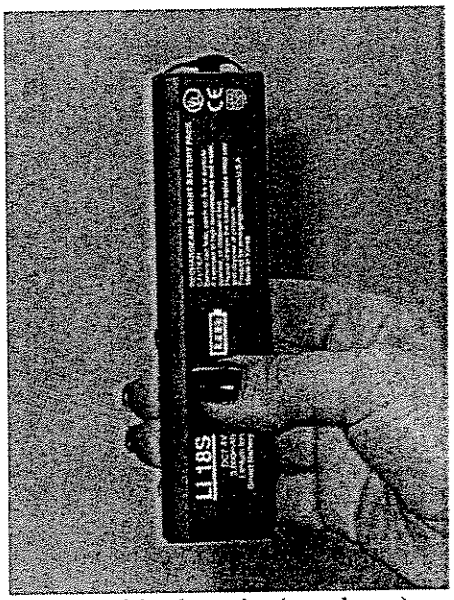
1. Locate and remove the shipping papers and documentation from under the lid's foam padding.
2. Remove the Innov-X Analyzer and all of the components from the protective carrying case and identify each on the enclosed shipping list.
3. Connect the battery charger to an 110V-240V AC power source. Place one Li-ion battery on the charger and charge it for at least 2 hours. Charge the second battery.
4. Charge the HP iPAQ using the attached AC adaptor for at least ½ hour.
5. Read and review the "Quick Start" section of the User's Manual. Innov-X recommends that you read the entire manual.
6. Install the fully charged battery into the analyzer.
7. Press the ON/OFF button on the base of the pistol grip on the analyzer and the power button on the iPAQ.
8. Select the desired analysis mode (i.e., Analytical, FastID, Pass/Fail or Soil). The instrument will undergo a one minute hardware initialization period.
9. Standardize the instrument with the 316 Stainless Steel mask. Standardize the instrument every 4 hours or as directed by the display.
10. If possible, release the software trigger lock and analyze a sample of known composition, in order to verify the correct operation of the analyzer.
11. Analyze samples of unknown composition.

1.1 COMPONENTS INCLUDED WITH THE ANALYZER

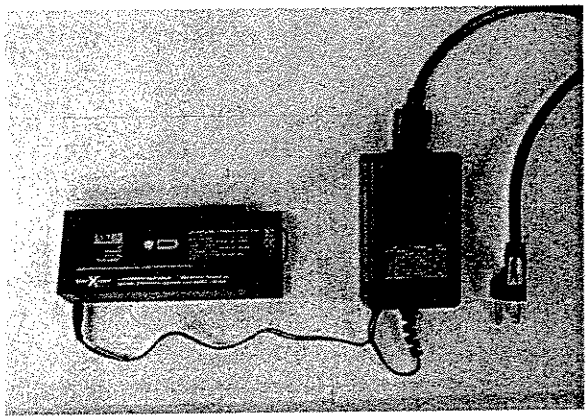
Shown here are the various items which are included with the Innov-X portable XRF analyzer. Unless otherwise noted, all items are standard accessories.



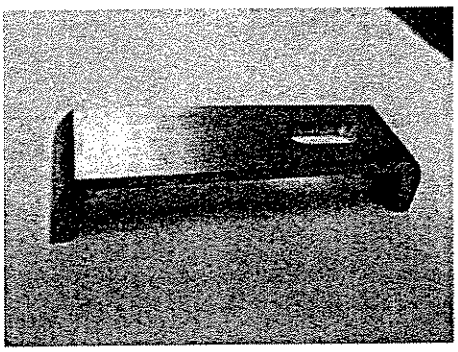
Analyzer, with iPAQ attached.



Two, Li-ion batteries (one shown).

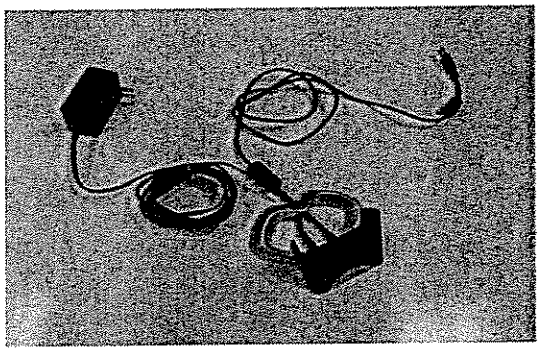


Battery charger and an AC adaptor. Battery shown mounted in charging system.

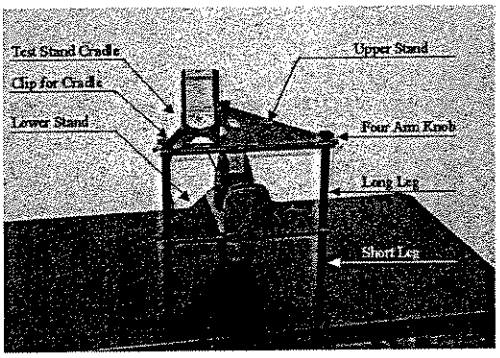


Standardization cap and weld mask (optional)

The standard standardization cap has no weld slit.



iPAQ cradle and AC adaptor. The cradle is used to connect the iPAQ to a PC for downloading data and reports.



Testing stand. This is the benchtop docking station for the analyzer. This accessory is standard with the XT-440 (environmental analyzer) and optional with other models.

1.2 QUICK START INSTRUCTIONS

The following section provides a quick overview to using the Innov-X portable XRF analyzer. This is intended to provide the basic startup and operational instruction needed to perform simple analyses. It is highly recommended that the user read the sections on Radiation Safety (Chapter 3) and the detailed description on operation (Chapter 4). The following Quick Start information is also provided as a separate, bound, laminated publication for quick reference.

1. Place a battery in the analyzer.
2. Power on the Analyzer (On/Off switch located on base of handle)
3. Power on the iPAQ (Button located in upper right hand corner of iPAQ)
4. Select Innov-X from the start menu located in the upper left hand corner of iPAQ screen.
5. Read the radiation safety notice and acknowledge that you are a certified user by pressing Start.
6. Select Desired Mode.
7. The analyzer will undergo a 60 second hardware initialization.

8. Place a standardization clip on the nose of the analyzer. Tap the button on the screen to standardize. *(Manual section 4.4 Standardization)*
9. When standardization is complete, remove the standardization clip.
10. Release manual trigger lock. (locked position is to the user's right if snout is facing away from user)
11. Release the software trigger lock by tapping the locked icon on the iPAQ screen and tapping yes in response to the software prompt.
12. Test standard to verify instrument performance.
13. Results will display on screen. Subsequent tests may be started from either the Results or Analysis screens.

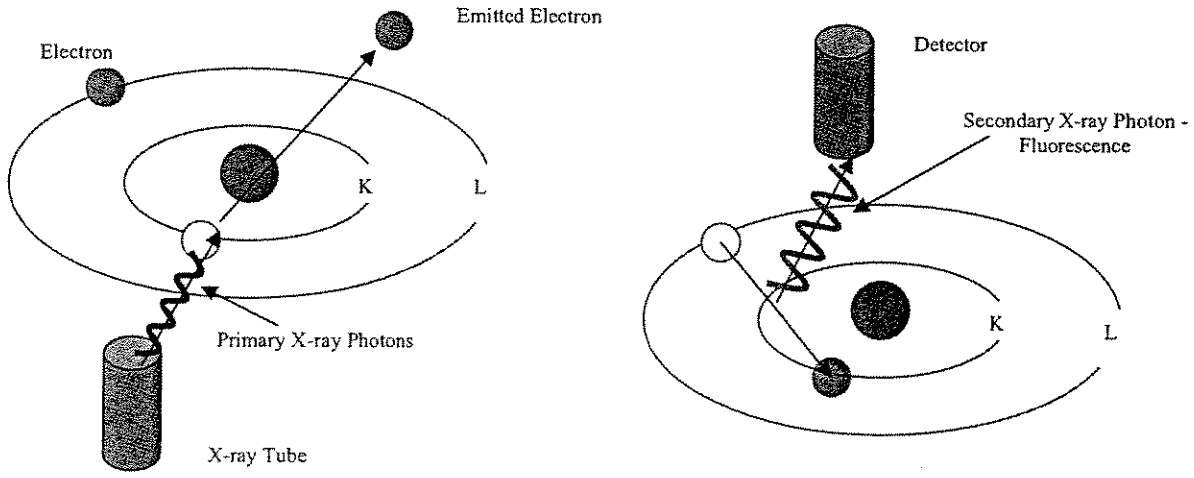
1.3 INTRODUCTION TO XRF: X-RAY FLUORESCENCE SPECTROMETRY OVERVIEW

Basic Theory

Although most commonly known for diagnostic use in the medical field, the use of x-rays forms the basis of many powerful analytical measurement techniques, including X-ray Fluorescence (XRF) Spectrometry.

XRF Spectrometry is used to identify elements in a substance and quantify the amount of those elements present. An element is identified by its characteristic X-ray emission wavelength (λ) or energy (E). The amount of an element present is quantified by measuring the intensity of its characteristic line. XRF Spectrometry ultimately determines the elemental composition of a material.

All atoms have a fixed number of electrons (negatively charged particles) arranged in orbitals around the nucleus. The number of electrons in a given atom is equal to the number of protons (positively charged particles) in the nucleus; and, the number of protons is indicated by the Atomic Number in the Periodic Table of Elements. Each Atomic Number is assigned an elemental name, such as Iron (Fe), with Atomic Number 26. Energy Dispersive (ED) XRF and Wavelength Dispersive (WD) XRF Spectrometry typically utilize activity in the first three electron orbitals, the K, L, and M lines, where K is closest to the nucleus. Each electron orbital corresponds to a specific and different energy level for a given element.



In XRF Spectrometry, high-energy primary X-ray photons are emitted from a source (X-ray tube) and strike the sample. The primary photons from the X-ray tube have enough energy to knock electrons out of

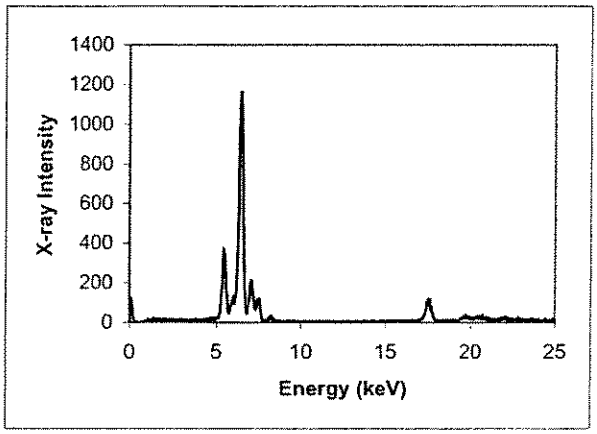
the innermost, K or L, orbitals. When this occurs, the atoms become ions, which are unstable. Electrons seek stability; therefore, an electron from an outer orbital, L or M, will move into the newly vacant space at the inner orbital. As the electron from the outer orbital moves into the inner orbital space, it emits an energy known as a secondary X-ray photon. This phenomenon is called fluorescence. The secondary X-ray produced is characteristic of a specific element. The energy (E) of the emitted fluorescent X-ray photon is determined by the difference in energies between the initial and final orbitals of the individual transitions.

This is described by the formula

$$E=hc/\lambda$$

where h is Planck's constant; c is the velocity of light; and λ is the characteristic wavelength of the photon.

Wavelengths are inversely proportional to the energies; they are characteristic for each element. For example the Kα energy for Iron (Fe) is about 6.4keV. The number of element-specific characteristic X-rays produced in a sample over a given period of time, or the intensity, can be measured to determine the quantity of a given element in a sample. Typical spectra for EDXRF Spectrometry appear as a plot of Energy (E) versus the Intensity (I).



History

Wilhelm Roentgen discovered X-rays in 1895. Methods for identifying and quantifying elements using XRF were first published by Henry Moseley in 1913. Much research and development of XRF continued after Moseley's pioneering work, especially during WWII when rapid developments in the aircraft, automotive, steel and other metals industries heightened the need to identify alloys quickly and reliably. However, the first commercial XRF Spectrometers weren't available until the early 1950's. Those systems were based on WDXRF technology and measured the characteristic wavelength of an element, one element at a time. Although the use of these systems was critical for elemental analyses, they were large, expensive, and required highly skilled operators to use and maintain them.

In the late 1960's, EDXRF technology, which measures the characteristic energy of an element, began to rival the use of WDXRF due to the development of Si (Li) solid state detectors, which offered better energy resolution of the signal. EDXRF systems offered the potential of collecting and displaying information on all of the elements in a sample at the same time, as opposed to one at a time with typical WDXRF systems. Many of the early EDXRF systems used radioisotopes for excitation instead of X-ray tubes, which could require changing sources to determine all the elements of interest. Some of those early EDXRF systems did not easily resolve multiple elements in a single analytical run.

As can be imagined, the equipment and applications of XRF Spectrometers have developed tremendously since the 1960's. Advancements in technology, electronics, computers, software and the use and

modification of them for XRF Spectrometers by instrument manufacturers, research scientists & engineers, and industrial users alike have led to the current state of the art in XRF Spectrometers. Now a mature technology, XRF Spectrometry is routinely used for R&D, QC and analytical services in support of production.

Elemental Analysis

XRF Spectrometry is the choice of many analysts for elemental analysis when compared to the other techniques available. Wet chemistry instrument techniques for elemental analysis require destructive and time-consuming specimen preparation, often using concentrated acids or other hazardous materials. Not only is the sample destroyed, waste streams are generated during the analytical process that need to be disposed of, many of which are hazardous. These wet chemistry elemental analysis techniques often take twenty minutes to several hours for specimen preparation and analysis time. All of these factors lead to a relatively high cost per sample. However, if PPB and lower elemental concentrations are the primary measurement need, wet chemistry instrument elemental analysis techniques are necessary.

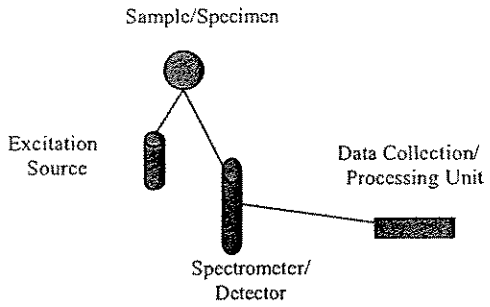
XRF Spectrometry easily and quickly identifies and quantifies elements over a wide dynamic concentration range, from PPM levels up to virtually 100% by weight. XRF Spectrometry does not destroy the sample and requires little, if any, specimen preparation. It has a very fast overall sample turnaround time. These factors lead to a significant reduction in the per sample analytical cost when compared to other elemental analysis techniques.

All elemental analysis techniques experience interferences, both chemical and physical in nature, and must be corrected or compensated for in order to achieve adequate analytical results. Most wet chemistry instrument techniques for elemental analysis suffer from interferences that are corrected for by both extensive and complex specimen preparation techniques, instrumentation advancements, and by mathematical corrections in the system's software. In XRF Spectrometry, the primary interference is from other specific elements in a substance that can influence (matrix effects) the analysis of the element(s) of interest. However, these interferences are well known and documented; and, instrumentation advancements and mathematical corrections in the system's software easily and quickly correct for them. In certain cases, the geometry of the sample can effect XRF analysis, but this is easily compensated for by grinding or polishing the sample, or by pressing a pellet or making glass beads.

Quantitative analysis for XRF Spectrometry is typically performed using Empirical Methods (calibration curves using standards similar in property to the unknown) or Fundamental Parameters (FP). FP is frequently preferred because it allows elemental analysis to be performed with no standards or calibration curves. This enables the analyst to use the system immediately, without having to spend additional time setting up individual calibration curves for the various elements and materials of interest. The capabilities of modern computers allow the use of this no-standard mathematical analysis, FP, accompanied by stored libraries of known materials, to determine not only the elemental composition of an unknown material quickly and easily, but even to identify the unknown material itself.

EDXRF Spectrometers

EDXRF Spectrometer systems are mechanically very simple; essentially there are no moving parts. An EDXRF system typically has three major components: an excitation source, a spectrometer/detector, and a data collection/processing unit. The ease of use, rapid analysis time, lower initial purchase price and substantially lower long-term maintenance costs of EDXRF Spectrometers have led to having more systems in use today worldwide than WDXRF Spectrometer systems.



EDXRF has been found most useful for scrap alloy sorting, forensic science, environmental analysis, archaeometry and a myriad of other elemental field-oriented analyses.

Handheld EDXRF Spectrometers for Field Analyses

It is clear that a future trend for elemental analysis is in rapid site investigation using techniques that are fast, inexpensive, reliable, and long-term cost effective. There is a need for immediate decisions to be made during the delivery of materials, industrial processing, and in the field for positive materials identification or environmental site assessment and remediation. It is also clear that EDXRF Spectrometry is the most suitable elemental analysis technique available for field analysis due to its simplicity, speed, precision, accuracy, reliability, and overall cost effectiveness.

Recent technological developments in cell phones, pocket PC's and other portable consumer electronics have led to the advancement of many high-performance, miniature components. X-ray equipment manufacturers began to take advantage of these developments in the late 1990's and developed Handheld EDXRF systems. An obvious advantage of Handheld EDXRF systems is that the analyzer is taken to the sample as opposed to bringing the sample to the analyzer and configuring it to fit in an analysis chamber. In addition to the per sample analytical cost savings, a key factor in using non-destructive EDXRF analysis, especially in the field, is the overall project cost savings due to improved and more timely decision making. The use of EDXRF for immediate positive materials identification or to guide an environmental site characterization will generally reduce the overall time required in the field due to the quick turnaround for the sample analysis; this invariably reduces the overall costs of analytical field work.

Of course, Handheld EDXRF technology has continued to evolve in concert with portable consumer electronic developments. Just like the early Benchtop EDXRF systems, early Handheld EDXRF systems used radioisotopes for excitation. There are several practical problems with the use of radioactive isotopes for handheld systems. The source decays and loses its testing speed over time. In addition to the loss in analytical capabilities, the sources have to be replaced incurring a cost. The use of radioactive isotopes also requires licensing (state-to-state in the US) and a radioactive materials control program; they are difficult to ship and transport, as they require hazardous materials declarations and/or permits. Consequently, the newest and most exciting development in Handheld EDXRF technology is the use of battery operated, miniature X-ray tubes, which was pioneered by the staff at Innov-X Systems.

Innov-X Systems Handheld EDXRF Spectrometers

Innov-X Systems specializes in Handheld EDXRF technology with the most advanced miniature components available for X-ray Tube sources, detectors, and PC 's. Innov-X Systems Handheld EDXRF Spectrometers are ideally suited for field analysis of alloys, lead-based paint, environmental soils, filters, dust wipes, forensics, archaeometry, and a variety of other elemental analyses in the field or around the plant. Innov-X Systems EDXRF Spectrometers are affordable, easy to use, reliable, and overall cost effective. The Innov-X Systems Handheld EDXRF units incorporate state-of the art components including a battery operated miniature X-ray tube, a high-resolution silicon pin detector, high speed data acquisition

circuitry, and a Compaq IPAQ Pocket PC® handheld computer for calculations, results and operator interface.

Innov-X Systems EDXRF Spectrometers offer the following invaluable features:

- Portable
- Battery operated, rechargeable
- X-ray Tube-based (Ag anode, 10-35kV, 10-100uA)
- Si PiN diode detector.
- Integrated pocket PC
- Pistol-shaped design for difficult testing locations and welds
- Auto-compensation for irregular or small samples
- Fundamental Parameters for no-standard analyses
- Stored Grade Libraries for rapid Grade ID's
- Stored Fingerprint Libraries for rapid material ID's
- Docking station available for use as standard benchtop unit
- Results shown after a few seconds of testing time.

For more information on how to utilize your Innov-X Systems Handheld EDXRF Spectrometer optimally, please review this Instruction Manual or contact us directly.

Chapter 2. Usage and Assembly of Accessories

2.0 ACCESSORIES

This chapter describes the various accessories that are provided with an Innov-X XRF analysis system. Included are:

- Batteries
- Battery Charger
- iPAQ cradle and charger
- Testing Stand Assembly (not standard with all units)
- Standardization Clip or Standardization Clip/Welding mask.

2.1 ANALYZER BATTERY

The Innov-X Systems XRF Analyzer is powered by a replaceable, rechargeable Lithium ion battery. In addition, the iPAQ has its own internal battery.

Innov-X Systems Main Battery

The Innov-X Analyzer uses a rechargeable Lithium Ion Battery. A picture of the battery is shown in Fig. 2.1. Two batteries are included with each analyzer. The batteries are charged an external battery charger. Batteries typically function for 3 to 6 hours, depending on usage patterns. Heavier duty cycles deplete the battery more quickly. Therefore, users who do longer and more frequent tests will need to replace their batteries more often than users who take shorter or fewer tests.

Figure 2.1. Li-ion Battery for analyzer

Battery power indicators:

There are two ways of determining the charge remaining on a battery: the LED indicator on the battery and the battery status icon on the analyzer screen. The battery icon, when tapped, will indicate the percent charge remaining on a battery inside the analyzer. Additionally, the battery icon will change from green to yellow when the battery gets low, indicating it has about 15 minutes left of charge.

To use the battery LED, push the button below the indicator. The lighting will indicate the % of charge. If possible, try to use batteries with at least 50% of their full charge, according to the indicator.

2.2 CHANGING A BATTERY

To change a battery, perform the following steps:

1. Hold the instrument by the handle, upside down, so the bottom of the instrument base is pointing upward. Please refer to Fig. 2.2.
2. Hold the instrument so that the nose is pointing away from the operator.
3. Remove the battery door from the bottom of the instrument base. The batteries have a small cord attached for ease of removal.
4. Pull out the existing battery, and replace with a new battery.
5. Insert the charged battery into the analyzer such that the connectors on the top of the battery are facing to the right (towards the On/Off switch). Note that the battery slot is keyed so that the battery can only be inserted one way.

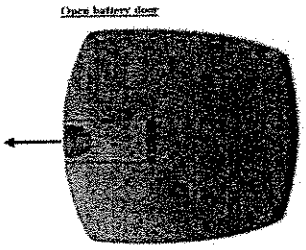


Figure 2.2a. Base of the instrument. Slide the door in direction indicated, reach into opening and remove battery.

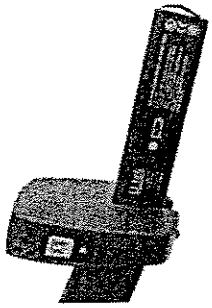

Figure 2.2b Insert new battery into opening. Note that labeling on the battery should be facing the ON/OFF switch.

2.3 BATTERY CHARGER

The battery charger is shown in Fig. 2.3. It takes about 2 hours to completely charge a battery. The status of the charger is shown by two lights on the power adaptor. Table 2.1 lists the information conveyed by the lights.

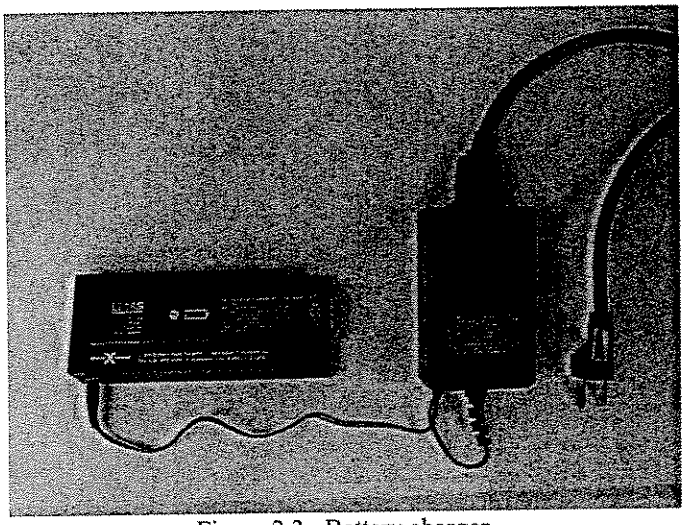

Figure 2.3. Battery charger.

Left Light	Right light	Status
On	Off	Battery is charging
On	On	Battery is 80% charged
Off	On	Battery is completely charged
Blink	Blink	Error. Remove battery and replace on charger. If error persists, call Innov-X Systems Technical support.
Off	Off	No battery is on charger

Table 2.1 Battery charger status lights

2.4 HP IPAQ POCKET PC BATTERY

The iPAQ has an internal rechargeable battery, which can be recharged by using the power adaptor that is included with the unit. This adaptor can be connected either to the iPAQ itself, or to the cradle. If it is connected to the cradle, and plugged in, the iPAQ will recharge whenever it is placed in the cradle. In addition, the iPAQ Battery will recharge whenever the iPAQ is mounted in an Innov-X analyzer which is powered, but not actively taking a test. The amber light on the top of the iPAQ will blink whenever the battery is charging. It will remain solid when the battery is completely charged.

Since the iPAQ will be recharged whenever the Innov-X Systems Analyzer is in use, it may never be necessary to use the iPAQ power adaptor. However, care should be taken when the analyzer is not used for a period of several days, as the iPAQ uses some power even when it is powered off. It is therefore possible to completely discharge the battery simply by not using the iPAQ for several days, or by using it for several hours without recharging it.

If you do not use your Innov-X Analyzer on a daily basis, or if you will have a down period of more than several days, it is recommended that you remove the iPAQ from the Analyzer when it is not in use and plug in the iPAQ to a power outlet to recharge it. This will ensure that your iPAQ is always charged and ready for use. You should also always plug in the power cord whenever the iPAQ is removed from the analyzer for data transfer.

If you do allow the iPAQ battery to discharge significantly, either by allowing it to sit too long unused, or by using it for a period of time without it being connected to a power source, it may not be possible to operate your analyzer. If this happens, the Innov-X software will provide an error message indicating that the iPAQ battery is too low. Recharge the iPAQ for at least a half an hour before attempting another measurement.

If the iPAQ battery is completely discharged, it will not be possible to turn on the iPAQ until it is recharged. A complete power failure will erase anything that is stored in the Main Memory of the iPAQ. All Innov-X program and data files are stored on the storage card, rather than in Main Memory, so you will not lose any data or have to reinstall the Innov-X software.

1. If the battery on the iPAQ is completely discharged, charge it for at least one half hour.
2. You will be required to follow the prompts on the iPAQ screen before you can use the iPAQ. This procedure involves realigning the screen by tapping in several spots, and going through a quick tutorial.
3. The iPAQ will reinitialize the Innov-X Systems software. A message will appear indicating that this is going to happen. You must tap ok to initialize.
4. The software will open automatically; a message will appear indicating that several registries have been restored. Tap ok to dismiss this message.
5. Set the clock to the current time. **Note, this is very important,** as your data is indexed by date. If the date in the iPAQ is incorrect, you may not be able to locate your results. The instrument will not allow you to take a reading until the date has been changed.
    a. From the Start Menu, tap Settings.
    b. Select the System tab, and tap clock.
    c. Set the proper date. Further details about this procedure can be found in the Compaq iPAQ user's manual.

2.5 REMOVING THE IPAQ FROM THE ANALYZER

It is very important to properly remove the iPAQ Pocket PC from the analyzer to avoid damaging the connector on the back of the iPAQ.

In order to remove the iPAQ, push the iPAQ retainer shown in Fig. 2.4 towards the front of the analyzer. Holding the retainer forward, grab the iPAQ from the sides, slide the iPAQ forward until it is clear of its connector, then tilt the front end up enough so it clears the front holder allowing the iPAQ to be lifted out of the instrument.

Note: Never grab the iPAQ and twist it side-to-side to remove it from the analyzer. Always move the iPAQ retainer forward as instructed above, slide the iPAQ forward and remove from the analyzer.

Figure 2.4. Removing the iPAQ from the analyzer.

2.6 STANDARDIZATION CAP and/or WELD TESTING MASK

All analyzers are supplied with either a standardization cap or a combination standardization cap welding mask. The standardization mask is the standard accessory. Welding masks can be purchased as an additional accessory, or in lieu of the standardization mask.

Standardization Cap

The cap clips on the front end of the analyzer and is used to standardize the system as described in Chapter 4. To attach the cap, snap it onto the nose of the analyzer over the Kapton window.

Combination Standardization Cap/Welding Mask

The standardization/welding mask is shown in Fig. 2.5. The cap clips onto the front end of the analyzer and is used to standardize the system as described in Chapter 4. To attach the cap, snap it onto the nose of the analyzer over the Kapton window. Be sure that when attaching the cap, that the solid end (as opposed to the end with the ¼" wide slit) is covering the window. To remove the mask, slide it off to either side.

The opposite end of the standardization cap serves as a welding mask. This mask is used to shield the base metal from analysis, when analyzing a weld. It is important to use this mask since failure to do so will produce an alloy chemistry that is a mixture of the base metal and the actual weld. For best results:

a. Use the welding mask only for welds that are larger than the opening in the mask;

b. Make solid contact between the surface of the mask and the material to test;
c. Use the mask only in the Analytical Mode – not with the standard Fast ID library;
d. Consider using longer test periods to compensate for the smaller testing area – especially with more difficult separations.

If it is desirable to use the welding mask in FastID mode, a user can create a special "Welding Mask Library." Teach all relevant alloys with the welding mask is in position. Make sure these fingerprints are saved in library that contains ONLY fingerprints taught with a welding mask. When measuring a weld, make sure the "Weld" library is the only one selected. By creating a special finger print library using the welding mask, a user can get good results in the Fast ID Mode as well.

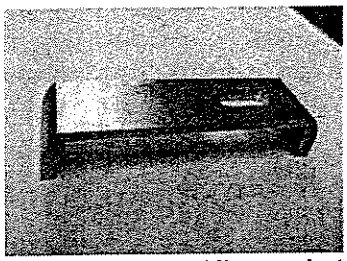

Figure 2.5 Standardization cap and welding mask. (Optional accessory)
The standard standardization cap does not have the welding slit.

2.7 TESTING STAND (optional accessory)

The testing stand is designed as a docking station for the handheld analyzer. It can be used as a bench-top system, or to test small samples. A list of components and an assembled stand is shown in Figure 2.6:

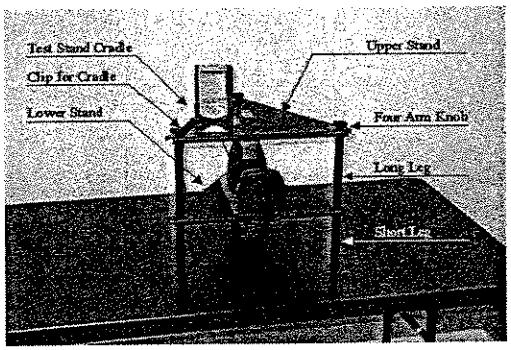

Figure 2.6. Assembled Testing Stand

Components of the testing stand:

1. Three (3) short legs
2. Three (3) long legs
3. Lower Stand
4. Upper Stand
5. Four (4) knobs for top plate
6. Test stand cradle
7. Clip for cradle.
8. Adaptor cable (connects serial connector on iPAQ cradle to auxiliary port on analyzer)

Assembly of Testing Stand

1. Insert the three Short Legs through the holes in the Lower Stand by inserting the threaded screw through the holes. This will balance the Lower Stand on the table top. (Fig. 2.7).

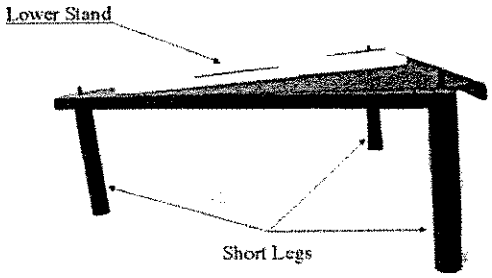

Figure 2.7. Mounting Lower Stand onto Short Legs.

2. Mount the three Long Legs onto the Lower Stand by inserting the threaded screws from the Short Legs into the holes on the Long Legs and turning until snug. Remove iPAQ from analyzer by following the instructions in Figure 2.4. Place the analyzer into the gap in the Lower Stand as shown. (Fig. 2.8).

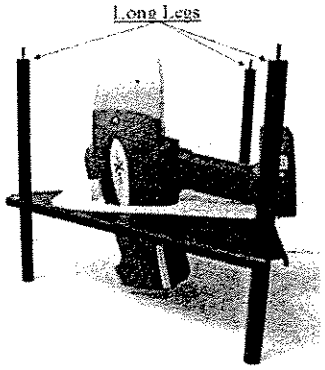

Figure 2.8. Mounting Long Legs onto Lower Stand and inserting analyzer.

3. Mount the Upper Stand onto the Long Legs. The Upper Stand has holes for the screws at the end of each of the Long Legs. The Upper Stand will also fit snugly over the front end of the analyzer. Be sure that the Upper Stand is mounted so that all three screws are inserted through the holes, and the front end of the analyzer is flush with the top surface of the upper stand. (Fig. 2.9).

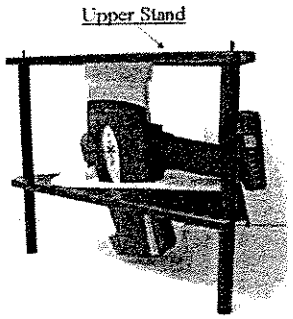

Figure 2.9. Mounting Upper Stand onto Testing Stand.

5. Put three knobs to secure testing stand onto analyzer. The iPAQ clip can be secured with any of the knobs. This clip grabs the base of the iPAQ cradle to hold the iPAQ securely in place.

6. Place the iPAQ in the cradle and connect it to the Auxiliary Port on the analyzer using the serial cable adaptor.

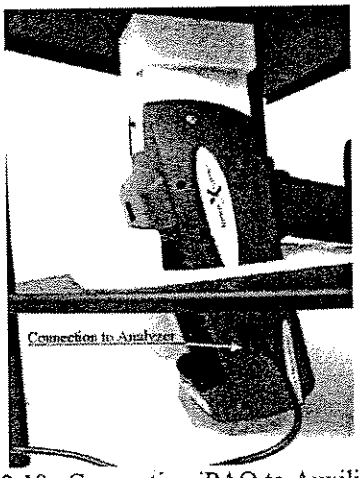

Figure 2.10. Connecting iPAQ to Auxiliary Port on analyzer.

3.0 Radiation Safety

3.0 IMPORTANT SAFETY INFORMATION

THE XRF SHOULD NOT BE POINTED AT ANYONE OR ANY BODY PART, ENERGIZED OR DE-ENERGIZED! The safe and proper operation of the Innov-X XRF instruments is the highest priority. These instruments produce ionizing radiation and should **ONLY** be operated by individuals, who have been trained by Innov-X Systems, Inc. and recieved a manufacturer's training certificate. Innov-X recommends that operators and companies implement a written Radiation Safety Program, with safety components specific to the site and application of use of the instrument. The Radiation Safety Program should be reviewed annually and revised appropriately by a competent individual.

The Innov-X analyzer is a very safe instrument when used according to manufacturer's recommended safety procedures as detailed in this chapter.

Radiation levels during testing are < 0.1 mR/hr on all surfaces of the analyzer except at or near the exit port for the radiation. This means that if an operator follows standard operating procedures, they will not obtain any detectable radiation dose above naturally occurring background radiation, on their hand while holding the analyzer, or on any area of their body.

This chapter details specifics of the radiation levels. It covers both standard (safe) and un-safe methods of operation, it provides radiation emission information, and also provides dose estimates for unsafe operations.

3.1 GENERAL SAFETY PRECAUTIONS AND INFORMATION:

Retain and follow all product safety and operating instructions. Observe all warnings on the product and in the operating instructions. To reduce the risk of bodily injury, electric shock, fire and damage to the equipment, observe the following precautions:

Heed service markings. Except as explained in this documentation, do not service any Innov-X product yourself. Opening or removing covers may expose you to electric shock. Service needed on components inside these compartments should be done only by Innov-X Systems, INC.

Damage requiring service:

- The power cord, plug or battery contacts for the battery charger are damaged.
- Liquid has been spilled or an object has fallen onto the instrument.
- The instrument has been exposed to rain or water.
- The instrument has been dropped or damaged.
- There are noticeable signs of overheating.
- The instrument does not operate normally when you follow operating instructions.

Safety Precautions:

Use the correct external power source: Ensure that the voltage is appropriate (100V-240 V/ 50-60 Hz) for charging the battery packs. Do not overload an electrical outlet, power strip, or convenience receptacle. The overall load should not exceed 80% of the branch circuit rating.

Use cables and power cords properly:
Plug the battery charger into a grounded electrical outlet that is easily accessible at all times. Do not pull on cords and cables. When unplugging the cord form the electrical outlet, grasp and pull the cord by the plug.

Handle battery packs properly; do not: disassemble, crush, puncture, short external contacts, dispose of in fire or water, or expose a battery pack to temperatures higher than 60 °C (140 °F).Do not attempt to open or service a battery pack.

WARNING: Danger of explosion if battery is incorrectly substituted. Replace only with Innov-X specified batteries. Used batteries may be returned to Innov-X Systems for disposal.

3.2 INNOV-X SYSTEMS – RECOMMENDED RADIATION SAFETY TRAINING COMPONENTS

Individual Companies and States have specific regulations and guidelines for the use of X-ray tube generated ionizing radiation. The purpose of the recommendations below is to provide generic guidance for an ALARA - best practice - approach to radiation safety. These recommendations do not replace the requirement to understand and comply with the specific policies of any state or organization.

1. **Proper Usage.** Never point the instrument at another person. Never point the instrument into the air and perform a test. Never hold a sample in your hand and test that part of the sample.
2. **Establish Controlled Areas.** The location of storage and use should be of restricted access to limit potential exposure to ionizing radiation. In use, the target should not be hand held and the area at least three paces beyond the target should be unoccupied.
3. **Specific Controls.** The instrument should be stored, in a locked case, or locked cabinets when not in use. When in use, it must remain in the direct control of a factory trained, certified operator.
4. **Time - Distance - Shielding Policies**. Operators should minimize the time around the energized instrument, maximize the distance from the instrument window, and shoot into high density materials whenever possible. Under no circumstances should the operator point the instrument at themselves or others.
5. **Prevent Exposure to Ionizing Radiation**. - All reasonable measures, including labeling, operator training and certification, and the concepts of time, distance, & shielding, should be implemented to limit radiation exposure to ***as low as reasonably achievable*** (ALARA).
6. **Personal Monitoring.** Radiation control regulations may require implementation of a radiation monitoring program, where each instrument operator wears a film badge or TLD detector for an initial period of 1 year to establish a baseline exposure record. Continuing radiation monitoring after this period is recommended, but may be discontinued if accepted by radiation control regulators. Please refer to Sect. 3.10 for a list of providers of film badges.

3.3 INNOV-X SAFETY FEATURES

The Innov-X analyzer is very safe when used correctly, however the analyzer does emit radiation through the analyzer window, and all precautions must be taken to reduce exposure to this radiation. In order to minimize the possibility of accidental exposure, the following safety features are standard in all Innov-X analyzers.

1. "Deadman" trigger. The trigger must be held for the duration of the test. This requires that the user consciously depress the trigger whenever x-rays are emitted, and ensures that the analyzer is attended at all times while x-rays are emitted.

   Upon completion of safety training, an INNOV-X certified trainer may deactivate this feature upon request. The deactivation of the trigger is recommended only if long tests are required (such as for soil mode) and if the unit is used primarily by only 1 or 2 users who utilize it frequently, in a

very controlled environment. In situations where multiple users are sharing the unit, it is recommended that the deadman trigger remain active.

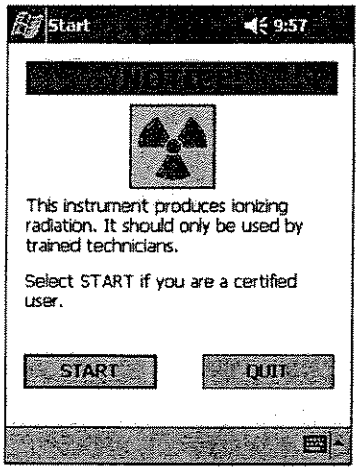
2. Software Trigger lock. In addition to the mechanical trigger lock, a secondary software trigger lock exists. Before using the trigger, the user must tap on a lock icon located in the lower right hand corner of the iPAQ screen. The user must then confirm that they wish to unlock the trigger. If the instrument is used continuously, the software trigger lock will remain off. If five minutes elapse between tests, the trigger will lock automatically.

3. Software Proximity sensor. The software requires that a sample be present in front of the analyzing window. This prevents the accidental exposure of bystanders to an open beam. If the analyzer detects that a sample is not present, it will abort the test and shut off x-rays two seconds after the test is started.

3.4 PERFORMING A TEST FOLLOWING APPROPRIATE RADIATION SAFETY PROCEDURES

Starting the Analyzer:

When an operator opens the Innov-X software on the iPAQ, he or she will be presented with the display shown to the right. Provided an operator has received training from an authorized Innov-X trainer, he/she should tap the START button to begin using the analyzer. From this point the operator is presented with the main menu of the analyzer to choose an operating mode and begin testing (described in Chapter 4). The remainder of this section is dedicated to operational and safety aspects that pertain to safe use and storage of the analyzer.



Starting a test using the trigger.

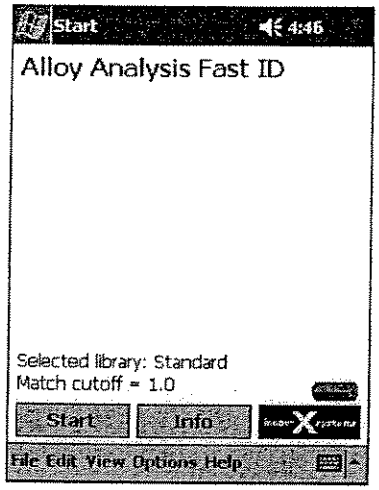
When the trigger is depressed, the analyzer supplies power to the x-ray tube and opens the shutter to emit x-rays. The analyzer is equipped with a trigger lock to prevent the user from accidentally beginning a test. Slide the lock from left to right to lock the trigger.

Recommended Operation: When the system is not in use, slide the trigger lock to the right to "lock" the trigger. This will prevent a person from starting a test accidentally when they grab the analyzer. The location of the trigger lock is shown to the right.

The trigger must be depressed for the duration of the test. Releasing the trigger will close the shutter and immediately end the test.

Figure 3.1 Handle of analyzer trigger and trigger lock are located at top of handle.

Starting a Test Using the "Start" Icon on the iPAQ Screen



This feature is disabled in all units shipped. It will become active only if the "deadman" trigger is disabled.

An operator may also begin a test by pressing the **Start** button on the touch screen, as shown at the right. The **Start** button, rather than the trigger, is generally used when the analyzer is docked into the testing stand. As an additional safety feature, the **Start** button also provides for "two handed" operation of the analyzer. To require two-handed operation, set the trigger lock by sliding the switch left to right. This will require the user to hold the analyzer with one hand and start a test by using the other hand to press the **Start** button.

This Feature is not available in Canada. All tests must be started via the trigger.

3.5 CORRECT AND INCORRECT INSTRUMENT USAGE:

The Innov-X XRF analyzer can be used in several different testing configurations. Safety guidelines are described for each configuration.

Configuration 1: Usage as a Handheld Alloy Analyzer:

In this configuration the analyzer is held in the hand, placed on various types of samples and a test is performed. Samples include pipes, valves, large pieces of scrap metal, basically any sample large enough to be tested in place, rather than held in the operator's hand. Point the instrument at a metal sample such that no part of your body including hands and/or fingers is near the aperture of the analyzer where x-rays are emitted.

Using the analyzer in this manner assures that the operator will not obtain a radiation dose to any body part or extremity in excess of naturally occurring background radiation. The radiation at any surface of the analyzer is < 0.1 mR/hr except at the exit port and the immediate area around the exit port.

The user should take care that personnel are not located within 3' (1 m) of the front end of the analyzer during testing, in the direction of the x-ray beam. Provided the analysis window is completely covered, there is virtually no radiation being emitted around the area of the sample. However, if a small component or curved surface is being analyzed, some radiation will be detectable.

Configuration 2: Usage in the Testing Stand

Innov-X strongly recommends that testing small pieces or small samples (rod, fasteners, turnings, XRF sample cups, bagged samples, etc.) be analyzed using the Innov-X Testing Stand. This allows the sample to be placed onto the analysis window of the analyzer without requiring the sample to be held by the operator. See figure below titled "Testing Stand Operation."

Note: If you are using the analyzer without the interlocked cover (as shown in Fig 3.2 below), be sure the analyzer is oriented such that the bottom of the handle is pointing towards the operator and the top of the analyzer (where the PDA normally is located during handheld operation) is pointing away from the operator. This configuration assures that any stray radiation emitted will be directed away from the operator, and there will be no detectable radiation exposure to the operator.

Note #2: Do not allow personnel to stand on the opposite side of the analyzer with respect to the operator's location as described in Note #1. Stray radiation may be emitted from the analysis area, particularly if the window is not completely covered, and that radiation will be directed upwards and away from the operator, provided the analyzer is oriented as described in Note #1.

Figure 3.2 Testing Stand Operation. Please refer to **Section 2.7: Testing Stand** for assembly instructions.

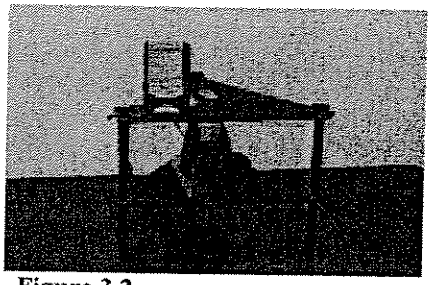


Figure 3.2.

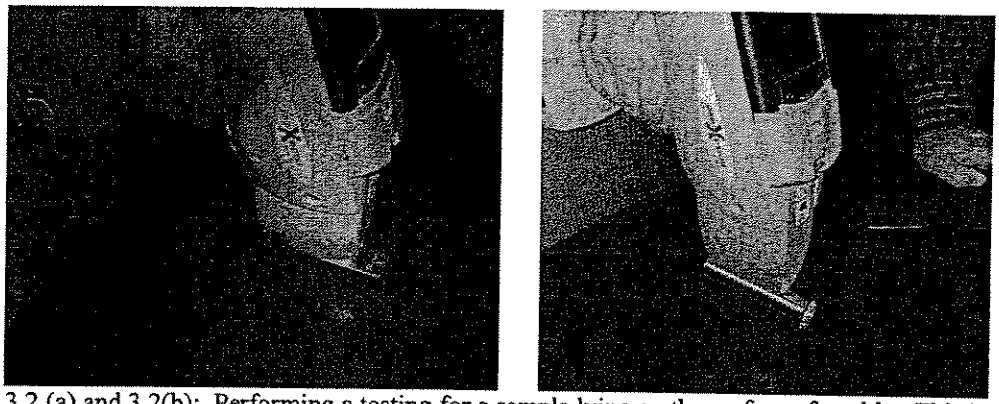
Warning: Innov-X strongly recommends that operators do NOT hold samples in their hand for testing. Never hold a small sample in your hand, and test that sample, such that your hand is exposed to the x-ray beam being emitted from the analyzer. This type of testing produces a small but non-negligible radiation dose to the operator's hand. Please see **Section 3.7: Radiation Doses for Several Scenarios** for dose levels. Also, see **Figure 3.4** for an example of incorrect usage.

Testing of Small Components:

Operators often are required to test small components, particularly in the field of alloy analysis. Examples of small samples include turnings, weld rod, wires, fasteners, nuts and/or bolts.

There are specific procedures to test small components. These procedures should be followed at all times. **Never hold a small part with your fingers or in the palm of your hand and perform a test. Doing so may deliver a significant dose of radiation to your fingers or hand.** Please refer to the Examples of Mis-use below.

Method 1: Testing a sample lying on a flat surface.



Figures 3.2.(a) and 3.2(b): Performing a testing for a sample lying on the surface of a table. This is a good way to test small samples, rather than holding them in your hand.

To analyzer small sample:

- Place the sample onto a flat surface.
- Place the window of the analyzer onto the sample and begin the test.

Safety Precautions:

Do not test samples in this manner at a desk or table where the operator is sitting are sitting. If the desk is made of wood or another non-metallic material, some radiation will penetrate the desk and may provide exposure to legs or feet if the operator is sitting at the desk or table.

Analytical Precautions:

If the sample does not completely cover the window, be sure the surface used does not contain metals or even trace levels of metals, as this may affect the accuracy of the XRF result. The XRF may report the presence of additional metals in the surface material. For this type of testing, it is good to place the sample onto a piece of 1100series aluminum alloy and perform the analysis. The operator should disable the aluminum analysis capability (See Section 8.3.3 in the manual for instructions).

Method 2: Use the testing stand as described above (see also Fig. 3.2).

Examples of Incorrect and Possible Unsafe Operation:

Improper Operation, DO NOT TEST SAMPLES LIKE THIS:

Exposure to the operator's hand/fingers will likely be minimal for this type of a testing, because the operator's hands and fingers are not in the primary beam. However, Innov-X believes that this type of the analyzer sets a poor safety precedent in that any operation where the operator places their fingers or hands near the window should not be permitted.

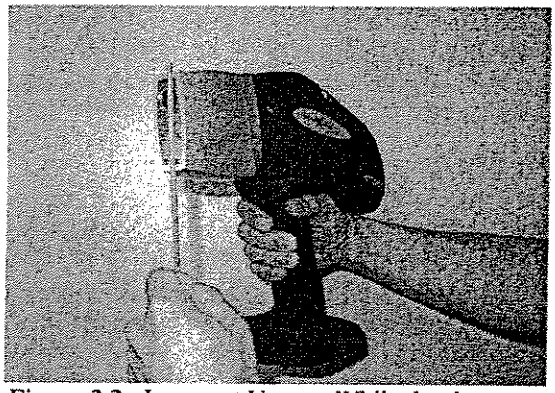


Figure 3.3. Incorrect Usage. While the dose to the operator's fingers/hand is negligible, testing this way sets a poor safety example for other operators, possibly encouraging other unsafe usage. Innov-X strongly recommends against this type of testing.

DO NOT TEST SAMPLES LIKE THIS:
Never hold a sample in your hand such that any part of your body or appendages are exposed to the x-ray beam. Testing samples in this way may generate significant radiation exposure (up to 27 R/hr) to the operator's fingers.

Figure 4.4 Extreme example of incorrect usage. An operator should NEVER hold small samples by hand

3.6 RADIATION WARNING LIGHTS AND LABELING:

3.6.1 Probe Light and Probe Label:

The Innov-X analyzer is equipped with warning lights that alert the operator when the tube is receiving power, and when x-rays are being emitted from the analyzer. Please see Fig. 3.5.

When the red light on the front nose of the analyzer is ON continuously (not blinking), this indicates the x-ray tube is receiving a low level of electrical power and the shutter is closed. The system is producing a low level of x-rays internally in this condition, but the shutter is providing adequate shielding to keep x-ray levels below levels of detection. The instrument is safe to be carried around or set down in this configuration.

When the red light is blinking, this indicates the tube is powered, the shutter is open and the analyzer is emitting x-ray radiation out of the analysis window. The analyzer should only be pointed at a sample, or be in the testing stand with a sample resting on the window, in this configuration.

3.6.2 Testing Light on Back of Analyzer:

The light on the back of the analyzer, shown in Fig. 3.6, is lit while a test is active. During a test – x-ray tube is energized and shutter is open – an LED on the back of the analyzer is lit. This LED remains lit until the test has ended. This light is for testing conditions (i.e. overhead) where the operator cannot see the Probe Light or the iPAQ display. The light turns off when the test is complete. When the light is off, the tube is de-energized and the shutter is closed.

3.6.3 Label Behind iPAQ:

The analyzer also has a label just below the iPAQ indicating, as shown in Figure 3.7:

CAUTION: Radiation. This Equipment Produces Radiation When Energized.

This label is required by most regulatory agencies. The term "When Energized" refers to the condition where the tube is fully energized and the shutter is open. This condition is also indicated by the red blinking light on the probe.

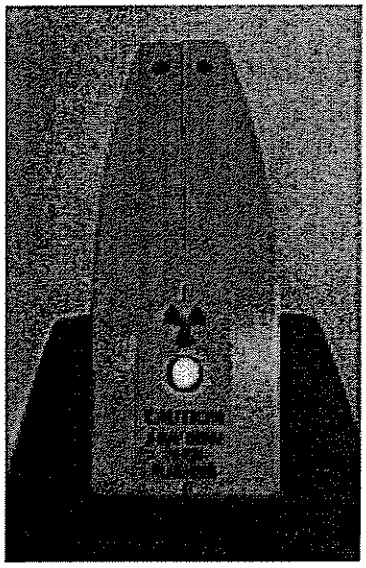

Figure 3.5. Probe light and labeling. When the light is on continuously, the x-ray tube is receiving minimal power and it is producing a minimum level of x-rays. The shutter is also closed so there is no radiation exposure to the operator or bystanders.

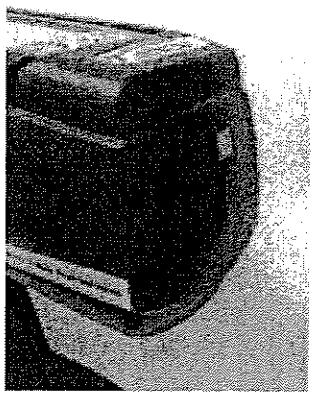

Figure 3.6. Back light on analyzer.

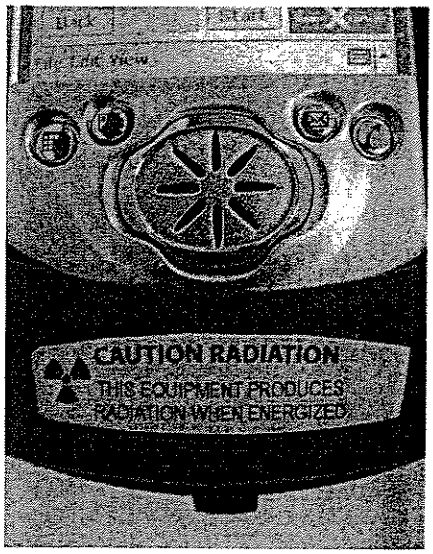

Figure 3.7. Label behind iPAQ.

3.7 RADIATION LEVELS FROM ANALYZER

Two pictures of the analyzer are shown below. In the first picture, all the relevant components referenced in this radiation safety section are displayed and labeled. The second picture shows a close-up of the front end of the window. The four sides A, B, C and D are indicated on this picture because they are referenced in terms of radiation levels output by the analyzer. The measured radiation levels for standard operating conditions are shown in the figures and tables below. Standard operating conditions are tube voltage operating at 35 kV, tube current of 5 uA, and 2 mm aluminum filtration.

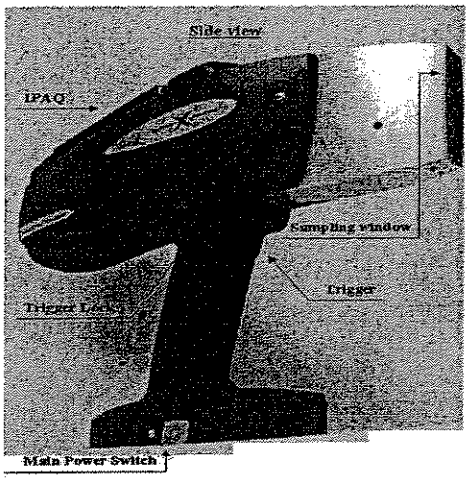

Figure 3.8 Innov-X Analyzer, Side View

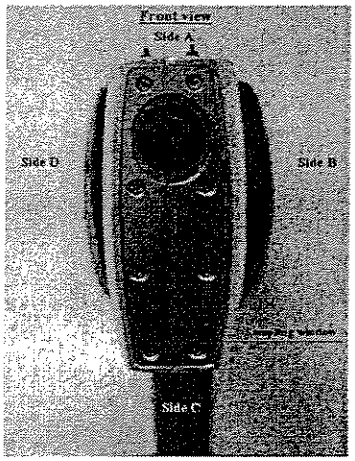

Figure 3.9 Innov-X Analyzer, Front View

Radiation Levels (mrem/hr) for Alloy Analysis, Standard Beam Conditions: 35kV, 5 uA, 2mm aluminum filtering:

Sample at Window	Trigger	Location A (Top)	Location B (Right Side)	Location C (Bottom)	Location D (Left Side)
Blank (Air)	<0.1	<0.1	<0.1	<0.1	<0.1
Metal	<0.1	<0.1	<0.1	<0.1	<0.1

Table 3.1. Dose rates (units of mrem/hr) at various locations with a metal sample covering the window and with no sample present. For "no sample" the analyzer is shooting the x-ray beam into air.

As shown in the Table 3-1, the dose to the operator's hand is negligible. The radiation levels at the side surfaces of the instrument snout (aluminum housing) are all <0.1 mrem/hour. Despite these low levels of radiation, there is no reason for any body part to be in the locations denoted A, B, C and D!

Table 3-2 shows the radiation levels directly in the x-ray beam that is emitted from the analyzer. Radiation levels at the exit aperture (or "port") are substantial. There is no reason for the operator or any personnel to be exposed by the direct beam. Operators should never hold samples in their fingers or cupped in their hands, as this may generate a significant radiation exposure.

Operations should never point the analyzer at another person and start a test, as this may also provide significant exposure to the person if they are within a few inches of the port of the instrument.

Radiation Levels in the Primary Beam Versus Distance from Port:
For Alloy Analysis, Standard Beam Conditions: 35kV, 5 uA, 2mm aluminum filtering:

Tube Conditions	At Trigger, or any part of operator's body.	At Window	4 inches	12 inches	36 inches	48 inches
35 kV, 5 uA, 2 mm Al filtering	<0.05	28,160	2,080	186	24	14
15 kV, 25 uA, thinner filter material	< 0.05	27,780	1,620	145	19	11

Table 3.2. Dose rates (units of mrem/hr) in the direct x-ray beam being emitted from the analyzer

3.8 RADIATION DOSES FOR SEVERAL SCENARIOS

In this section we provide data, concrete examples of use and misuse of the analyzer and common questions and answers we encounter when training personnel on the safe use of the Innov-X analyzer. The goal is to explain scenarios of safe versus improper usage of the analyzer.

The table below presents radiation doses for normal operating conditions and also for examples of misuse of the analyzer and even extreme misuse. Innov-X provides installation training that includes detailed radiation safety training and documentation designed to prevent misuse of the analyzer.

Example of Instrument Usage	**Radiation Exposure and Comments**
Normal Operation - Dose to Hand: User analyzes samples according to standard operating procedures described in this manual. Assumption: Operator using system with x-ray tube ON for 8 hours/day, 5 days/week, 50 weeks/year. (Practically constant usage).	Maximum exposure is to operator's hand, at the trigger. Exposure is < 0.1 mrem/hr. Annual exposure to hand is then < 200 mrem (2uSv). US: Maximum exposure under OSHA regulations is 50,000 mrem annually. Thus continuous operation provides a dose that is at least 250 times lower than maximum allowed by OSHA. Canada: Maximum exposure under ICRP regulations is 500 mSv for radiation workers and 50 mSv for the general public. Thus continuous operation provides a dosage 250 times lower for a radiation worker and and 25 times lower for the general public.
Normal Operation – Dose to Torso: Analyzer is used under the same operating conditions described above.	Exposure to Torso is so low it cannot be measured. To be conservative we use the same figure as the trigger, < 0.1 mrem/hrAnnual exposure using highly conservative operating conditions above is < 40 mrem. (0.2 uSv) Maximum allowed is 5,000 mrem under OSHA and 20 mSv under ICRP for radiation workers (1 mSv for general public).

Misuse Example 1:
Operator holds samples in front of window with fingers, such that fingers are directly in the primary beam. Do not do this!.

For fingers at the port, in the primary beam, the maximum dose to the fingers is 27,000 mrem/hr. Assume an operator performs a 10 sec test (typical). The dose to the operator's fingers or hand is 27,000 x (10/3600) = 75 mrem. If the operator did this 666 times/year they would exceed the allowable annual dose of 50,000 mrem to an extremity.

If the test time was 30 seconds instead of 10 seconds, the operator would exceed the annual safe limit of 50,000 mrem after 222 tests.
Even though it is unlikely to make this mistake so many times in a year, do not even do it once. Take the extra time to test a sample on a surface or use a testing stand.
Dose is about 440 mrem/year 4.4 mSv (year).
Maximum allowed dose is 50,000 mrem/year (US OSHA), 500 mSv/year (Canada ICRP radiation worker) or 50 mSv/year (Canada ICRP general public).

Misuse Example 2:
Operator places analyzer against body and pulls the trigger to start a test. Analyzer tests to preset testing time (usually 10 seconds) unless operator pulls trigger again to stop test. This applies to analyzer being in contact with operator or with bystander.

Dose at exit of sampling window is 27,000 mrem/hr.
Dose for a 10 second exposure with analyzer in contact with Torso: 75 mrem (.75 mSv).
US: If an operator did this act 66 times in a year, the operator would exceed the annual safe dosage to the torso.

If the testing time was 30 seconds instead of 10 seconds, thus the operator placed the port against his body or that of a bystander and performed a 30 second test, the dose would be 225 mrem. This is about the same as a mammogram. Repeating this gross mis-use 22 times would exceed the annual allowable limits.
Canada: Radiation worker would have to repeat this example of gross misuse 26 times to achieve the ICRP level of 20 mSv. (general public 1.3 times to achieve limit of 1mSv)

Misuse Example 4:
Operator manages to initiate a test for 10 seconds and exposes a bystander that is standing 12" away from analyzer port. What is exposure to bystander?

Note: The proximity sensor would automatically shut down the x-ray tube after 2 seconds, so this is an extremely improbably occurrence.

Note 2: Equations to scale these to other scenarios involving longer or shorter tests, and bystander being at distances other than 12" are provided at right.

Dose to bystander at 1 foot is 350 mrem/hr. For a 10 second exposure dose is 1 mrem. This is 5,000 times lower than the allowable dose to a worker in a year. This would have to happen 5,000 times to for that worker or bystander to obtain the maximum allowable dose.

Formula for calculating other scenarios:

$$Dose = 1\,mrem \left(\frac{13.25}{D + 1.25} \right)^2 x \left(\frac{t}{10} \right)$$

D = distance from port in inches
T = testing time

Example: Bystander is 3' away from port for a 30 second test. In this case the dose is calculated as:

$$Dose = 1\,mr \left(\frac{13.25}{36 + 1.25} \right)^2 x \left(\frac{30}{10} \right) = 0.38 mrem$$

US OSHA: Maximum allowable level is 5,000 mrem assuming bystander's torso is exposed. Thus, this misuse would have to occur 12,500 times in a year to the same bystander before that bystander achieved his maximum allowed dose.
ICRP: 5000 times for rad worker, 250 for general public

Comparative: Radiation Doses from Typical Exposures to Ionizing Radiation

Common medical and/or dental x-rays:	20-30 mrem each.
Mammogram:	100-200 mrem
Flying in a commercial jet coast to coast (6 hrs.):	1-2 mrem.
Daily exposure from background radiation: * depends on geographic location	0.3 to 0.5 mrem/day

Table 3.3 Radiation Doses from Typical Exposures to Ionizing Radiation

From the above table, nearly all the cases of analyzer misuse produce radiation exposures similar to flying in a commercial aircraft. Moreover, the typical exposure from a case of significant instrument misuse produces roughly the same dosage as the daily dose of radiation from naturally occurring background radiation.

3.9 COMMON QUESTIONS AND ANSWERS REGARDING RADIATION SAFETY

Question: When I'm shooting a piece of pipe or valve on a rack or on a table top, is there any exposure to people standing in other locations, or standing several feet away from the analyzer?

Answer: Even a thin amount of metal sample (1-2 mm thickness) is enough to completely attenuate the x-ray beam emitted from the Innov-X analyzer. Shooting a piece of material that covers the sampling window on the analyzer will completely shield any bystanders from radiation exposure. However, good practice recommends that the area for at least 4-5 feet in front of the analyzer is clear of people.

Question: If I forgot to switch the safety on the trigger to "ON", I pick up the analyzer and accidentally pull the trigger, is that dangerous to nearby personnel?

Answer: No, this example of misuse is not dangerous, but it may produce a non-negligible radiation exposure to nearby personnel. For an exposure to occur, the following things must happen. First, you must be holding the analyzer so that a bystander is actually standing in the x-ray beam being emitted. Just being near the analyzer is totally safe otherwise. Second, the bystander must be within 1-3 feet from the nose of the analyzer in addition to being in the beam path, to receive any appreciable dose. If all of these conditions are true, the dose received by a bystander is still extremely low. It ranges between 0.1 to 0.5 mrem depending on the exact location of the bystander. This dose is 10,000 to 50,000 times less than the allowed dose. Please see Misuse Example 4 in the table above.

Question: Do I need to create restricted areas where I am using the analyzer?

Answer: No, provided you are following normal operating procedures there is no reason to restrict access to an area where the analyzer is in use. The operator should take precautions to keep any personnel more than 3 feet away from the sampling window of the analyzer in the event of accidental misuse as detailed above. Should the operator also elect to test small components like weld rod as shown in Figure 3.3, the operator should also be sure that no personnel are standing within about 4-5 feet of the sampling window.

Question: How does the x-ray tube in the Innov-X system compare to a radiography system used for taking images of metal parts.

Answer: The x-ray tube used in the Innov-X system produces between 1,000 and 10,000 times lower power than most radiography systems (0.5-1 watt for Innov-X versus kW for radiography systems). This is because a portable XRF is designed to perform surface analysis of alloys and other samples, whereas radiography systems are designed to shoot x-rays entirely through metal components in order to obtain an image on the other side of the object being bombarded with x-rays. For example, many tube-based radiography systems use a 300-400 kV tube and currents in the tens or hundreds of milliamps (mA). The Innov-X analyzer uses a tube operating at 35 kV and 5-30 micro-amps. The radiation levels produced are therefore thousands or tens of thousands times lower with the Innov-X system.

Question: Should we use dosimeter badges with the Innov-X analyzer.

Answer: Dosimeter badges are required by some states, and optional by other states. Innov-X recommends that operators wear badges, at least for the first year of operation, as a general precaution to flag any misuse of the analyzer. Dosimeter badges are available for the torso (generally worn on the belt loop or shirt pocket) and are available as "ring" badges. The best single badge to obtain is a ring badge that is worn on a finger, on the opposite hand used to hold the analyzer. This will record accidental exposure for the most likely case – an operator grabbing a small sample and holding it in one hand while analyzing it. Note: these badges generally have a threshold of 10 mrem, and are renewed monthly. So it will take several cases of misuse even to obtain a reading on a typical badge. When purchasing a badge, obtain the type used for x-ray and low energy gamma ray radiation.

3.10 SAFE GUARDS AND EMERGENCY RESPONSE

The main safeguards to use as an owner of an Innov-X portable XRF are really intended to restrict access to properly trained operators:

1. Keep the system in a controlled location, where only authorized users are likely to have access to the analyzer at any given time.
2. Make a simple sign that is kept with the analyzer indicating that an operator must have completed a training class provided by your company or must have attended an Innov-X training course in order to use the analyzer. Note that when the Innov-X system is turned on, the screen displays a message indicating that the system should only be used by authorized personnel.

Emergency Response:

Because the Innov-X system is a battery operated, x-ray tube based analyzer, the emergency response plan is very simple. If the operator believes the analyzer is locked up in an "OPEN" position, they should do two things:

1. Press the On/Off switch on the base to power the analyzer off. The green LED indicator will turn off, indicating system power is off. At this point it is not possible for the analyzer to be producing x-rays.
2. As an additional precaution, the operator may remove the battery trap door at the bottom of the analyzer (have the nose pointing away from personnel), and pull out the battery. Even if the operator has failed to properly power the system off in Step #1, removing the battery guarantees that no x-rays can be produced. There is no electrical power being provided to the x-ray tube.

Note: It would be highly unusual for an operator to somehow lock up the analyzer with the x-ray tube powered on. This would require the operator to crash the iPAQ during an analysis. If this happens the analyzer will shut off the x-ray tube 10 seconds after the last communication with the iPAQ. However, if at any time the operator believes the x-ray tube is on and no test is in progress, powering off the analyzer and restarting will automatically shut down the x-ray tube and close the shutter. It will no longer be possible to produce x-rays at this point.

3.11 DOSIMETER BADGES

Dosimeter badges are provided as a monthly service by several companies, listed in this section (see below). The badges are generally provided monthly, and the operator returns the previous month badges to the company for analysis. The operator receives a monthly report showing any personnel with readings higher than typical background radiation.

Dosimeter badges are required by some states, and optional by other states. Innov-X recommends that operators wear badges, at least for the first year of operation, as a general precaution to flag any misuse of the analyzer. Dosimeter badges are available for the torso (generally worn on the belt loop or shirt pocket) and are available as "ring" badges. The best single badge to obtain is a ring badge that is worn on a finger, on the opposite hand used to hold the analyzer. This will record accidental exposure for the most likely case – an operator grabbing a small sample and holding it in one hand while analyzing it. Note: these badges generally have a threshold of 10 mrem, and are renewed monthly. So it will take several cases of misuse even to obtain a reading on a typical badge. When purchasing a badge, obtain the type used for x-ray and low energy gamma ray radiation.

Dosimeter Companies:

Here are two companies that provide badges as a regular service. There are certainly many more.

Landauer Inc.	AEIL
Glenwood, IL	Houston, TX
708-755-7000	713-790-9719

3.12 TYPICAL REGISTRATION REQUIREMENTS

Innov-X maintains a database of the registration requirements for every state, including sample registration forms. Most states require some form of registration, and generally they require the registration to be received within 30 days of receipt of the instrument. Some states require no registration, while a few require notification in advance. Please contact Innov-X for specific questions regarding the state where the instrument will be used, or for copies of registration forms.

In general a company will have to provide the following information regarding the device:

1. Purpose of device. Generally this is "Analytical" or "Industrial." Be sure to inform the state registration office that the device will NOT be used for radiography or for medical uses.
2. Radiation Safety Officer – Monitors training, safe use, and controls access to the instrument.
3. Authorized Users – Trained by Innov-X Factory Authorized Representatives in the safe and proper use of the XRF.
4. Operating parameters of the analyzer – 35 kV, 5-30 micro-amps.
5. Type of system, either fixed, mobile or portable. Generally the correct choice is "Portable."
6. User Training Specified – Indicate that only individuals receiving manufacturer training, documented by a manufacturer's training certificate will operate the instrument.
7. Personal Monitoring. This may be required by radiation control authorities. Many registration forms will ask that you indicate whether or not you intend to perform dosimeter monitoring.
8. Copy of Registration & Manual at the Job Site

If you have any questions regarding the type of registration form or filling out the form, please contact Innov-X Systems. Many states may confuse a portable XRF system that uses a tube with medical or industrial radiography systems. This is because of the relative newness of portable tube-based systems. In all likelihood, Innov-X personnel have experience providing the necessary documentation to the state in question, and can readily assist the customer in this process.

4.0 Operation

4.0 OPERATION - GENERAL

Power to the instrument is controlled by the ON/OFF button on the base of the pistol grip. The green LED next to this button will illuminate when the analyzer power is on. The iPAQ operates on the Microsoft Windows CE ® operating system and is activated separately by the power button on the right top face, just over the display. The trigger is locked via the software and can be locked manually by moving the trigger lock found just above the trigger.

4.1 WORKING WITH THE HP iPAQ Pocket PC®

The Microsoft Windows CE ® operating system and Innov-X software provided on the iPAQ handheld computer are operated by user input through the touch screen. For comprehensive details on the iPAQ's operation, please refer to the iPAQ reference materials included with your unit.

General tips

- The Start Menu is found in the upper left corner of the iPAQ screen. This is used to launch all applications, including the Innov-X Systems Analyzer software.
- The instrument is designed as a "point and shoot" system that requires little, if any, entry of information for most operations. In the event the user modifies the grade library, enters testing information data, or performs other functions, it will be necessary to enter data via the virtual keyboard, which can be accessed by tapping the keyboard icon in the lower right corner. The iPAQ also includes character recognition software. This can be selected from the drop-down menu to the right of the keyboard icon.
- The File toolbar which will be used to Change Functions, Screens and Options is located at the bottom of the screen.
- It is possible to cut, copy, rename and delete files from within Windows File Explorer by selecting the file to be modified and holding the stylus on the screen for 2 seconds.
- Pressing buttons on the bottom of the iPAQ will perform various functions that are described in the iPAQ documentation. The button on the right hand size of the analyzer is the iPAQ task manager. Pressing this button will show all programs that are currently open. Open files can be closed from this menu. Simply hold the stylus on the file for a few seconds. The option to close the file will appear.

4.2 OPERATION - MAIN SOFTWARE SCREENS

The Innov-X Software consists of three main screens:

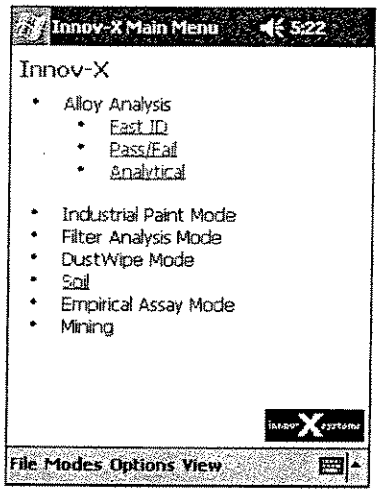
- **Main Menu screen:** Used to select the analysis mode, open the results screen, and change the administrator password.
- **Analysis Screen:** Used to change settings, edit libraries, and perform tests.
- **Results Screen:** Displays results from current reading, allows scrolling back to previous test results. Allows recorded data to be exported to a comma delimited file which is directly compatible with Microsoft Excel.

4.2.1 Innov-X Main Menu

The main menu below appears upon startup. The Main Menu allows you to choose an analysis mode, as well as perform certain administrative functions such as changing your login password. The modes which

are available on the analyzer are shown in blue. For information on adding additional analysis modes to an analyzer, please contact the Innov-X Sales Department at 781-938-5005.

- **Use the Main Menu to select the desired analysis mode.** The analysis mode can be selected by either tapping on the name of the method (shown in blue) or by selecting the appropriate mode from the Modes menu.
- The administrative password can be changed by selecting ***Options → Change Password.***
- It is possible to go directly to the Results Screen by selecting ***View→Results***. If the results screen is opened in this manner, it is possible to view results when the iPAQ is not connected to the analyzer.

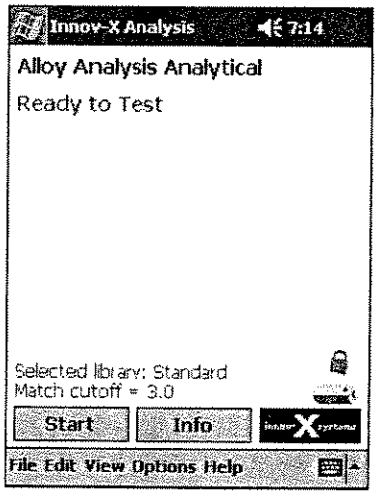


4.2.2 The Analysis Screen

Selecting a mode opens the analysis window for that mode. All data acquisition and analyzer control are done from this window. This window allows the user to start or stop an analysis, change testing parameters, and modify the fingerprint and grade libraries (Alloy Analysis only).

The analysis screen runs continually while during normal instrument operation. From the results menu, it is always possible to go back to the Analysis screen by selecting ***File→Exit*** or by tapping the X in the upper right hand corner of the screen.

The analysis screen for Analytical mode is shown to the right. Screens from other modes are similar and will be described in later in this manual. The analysis screen shows the name of the mode that is currently active, a start/stop button (which is inactive in most cases), an info button that is used to enter descriptive information for any given test, a trigger lock and a battery indicator. In addition, a message appears directly below the name of the mode which will indicate the current state of the analyzer. Typically it reads "Ready to Test," but also provides other information in certain circumstances. Any mode specific information will be displayed at the bottom of the screen above the menu choices.

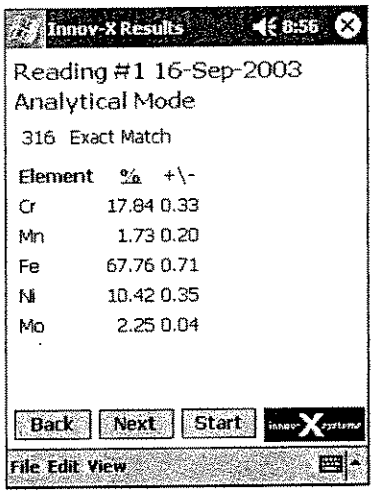


4.2.3 The Results Screen

The Results screen displays the current reading and old data. All data handling functions such as exporting and deleting readings are carried out from this screen. Once the Results Screen is open, the user may start new tests without going back to the analysis screen by pulling and holding the trigger. Tapping the X in the

upper right hand corner will return the user to the analysis screen without starting a test. If no analysis mode is running, an Exit button will appear which will close the Results screen.

The Results screen is automatically shown at the completion of any analysis. It can also be accessed from the analysis screen for any mode or the **Main Menu**, by selecting ***View→Results***. Once the Results screen has been opened, the information which is displayed can be changed by selecting options from the View menu. The various viewing options will be described in detail in later chapters.

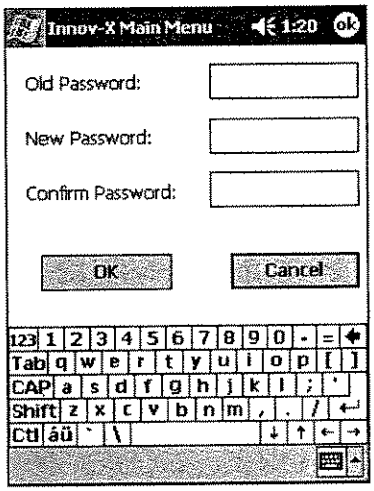


4.3 PASSWORDS - ABOUT PASSWORD PROTECTION

Certain functions such as adding and deleting fingerprints from the libraries, and Pass/Fail setup have been specified as Administrative Level Functions. These functions are described in detail in later sections of the manual. In order to use these functions, a password must be entered. The default password is set as the lowercase letter "z". This password can be entered whenever the system prompts for a password.

Changing the Administrator Password.

The Administrator password may be changed at any time from the **Innov-X Main Menu** by choosing ***Options→Change Password.*** When the change password option is selected, this screen will appear.



If you are changing the password for the first time, enter the letter "z"; otherwise enter the current system password. Then, choose a password and enter it twice, once in the "New Password" box and again in the "Confirm Password" box. Passwords may be any combination of letters or numbers.

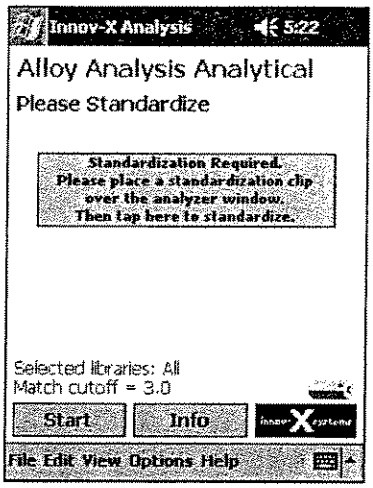
4.4 STANDARDIZATION

4.4.1 Standardization Procedure

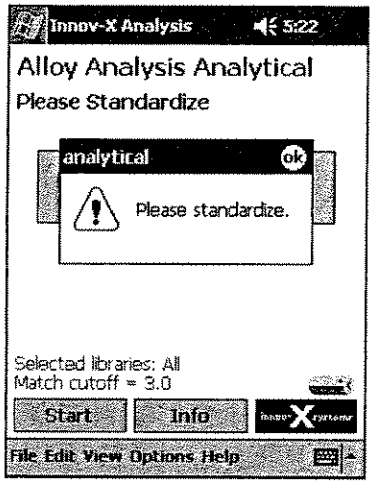
Before performing tests, it is necessary to standardize the instrument. This automated procedure involves collecting a spectrum on a known standard (Alloy 316) and comparing a variety of parameters to values stored when the instrument was calibrated at the factory. If there are any problems with the instrument, they will be indicated by an error message.

The standardization procedure takes about 1 minute. Standardization must be done any time the analyzer hardware is initiated or restarted and must be repeated if the instrument is operating for more than 4 hours. It is possible to re-standardize the instrument at any point while the software is running. Standardization is always initiated from the Analysis Screen of any Mode.

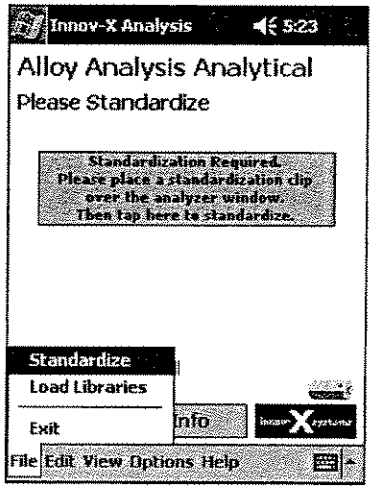
If the analyzer is restarted, you will be required to standardize the instrument before performing any measurements. This is indicated by the message "**Standardization Required. Please place a standardization clip over the analyzer window. Then tap here to standardize.**" on the analysis screen



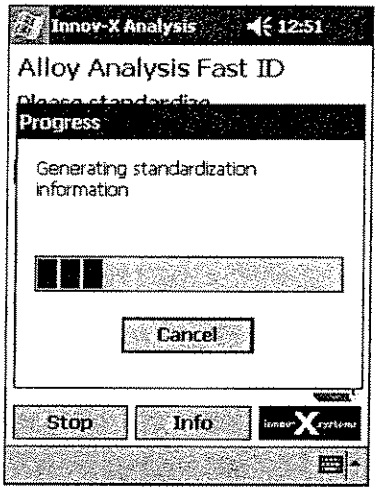
It is not possible to start a test before standardization. If the trigger is pulled before the standardization procedure is completed, a message box will appear. Press **ok** to acknowledge and clear the message.



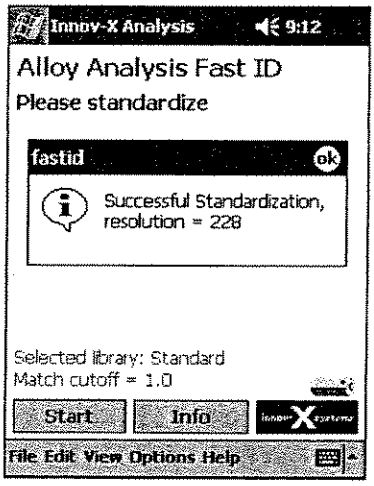
To initiate the standardization procedure, snap the standardization piece on the front of the instrument. Verify that it completely covers the analyzer window. When using a standardization mask with a weld collimator, be sure that the solid portion of the mask covers the analyzer window. Tap the grey box in the center of the screen or select ***File→Standardize*** to begin.



When standardization is in progress, the red light on the top of the instrument will blink, indicating that the X-ray tube is energized and the shutter is open. In addition, the amber light on the back of the instrument will illuminate and a status bar will appear, tracking the progress of the measurement.

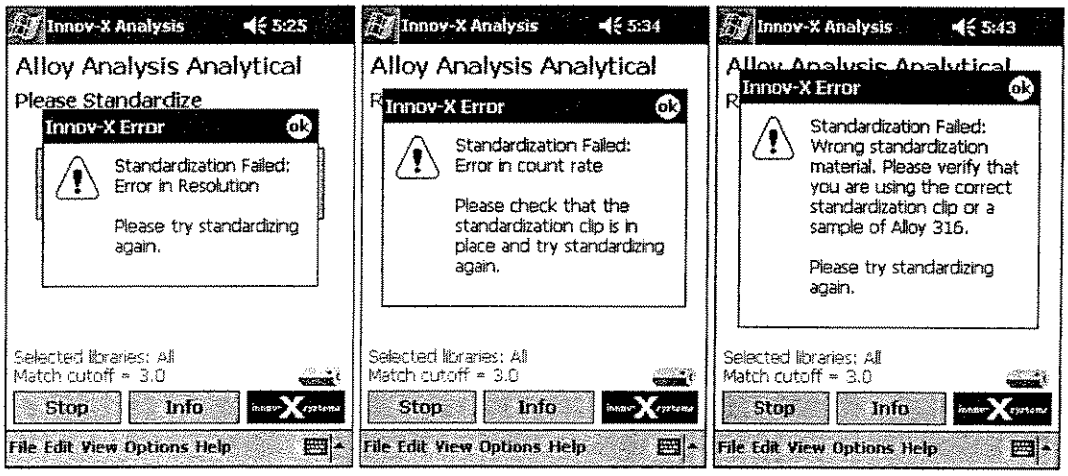


When standardization is complete, the message "Successful Standardization" will appear, along with the resolution of the instrument. Tap **ok** to acknowledge and clear the message. The instrument is ready for testing.

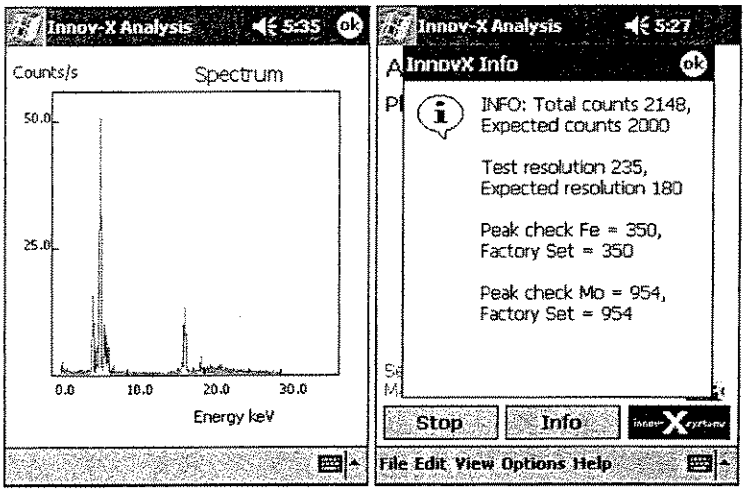


4.4.2 Standardization Errors

The analyzer performs several diagnostic checks during the standardization process. If the standardization fails, the instrument will prompt the user regarding the next step. Several errors could occur while standardizing: "Wrong Standardization Material," "Error in Resolution" or "Error in Count Rate"

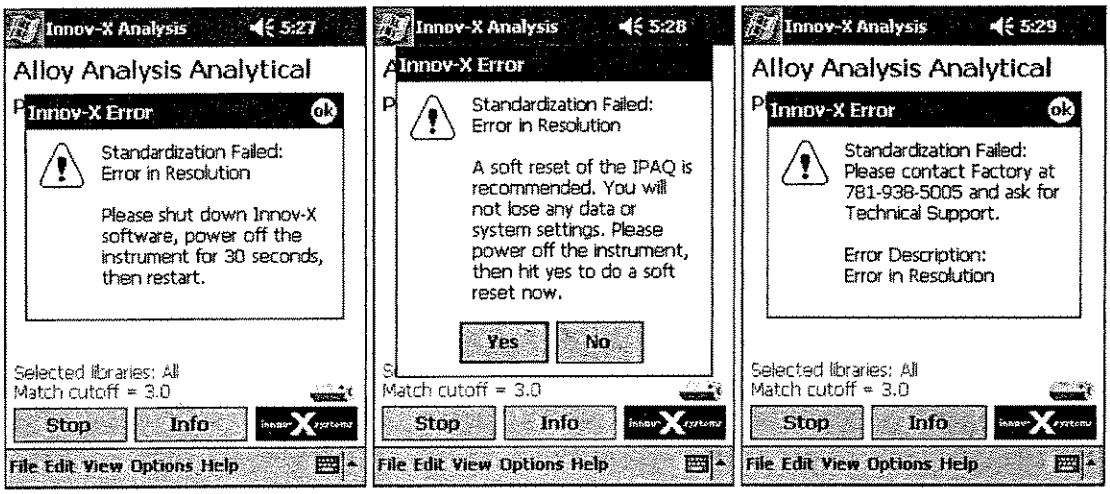


After closing the Standardization Failed message, two additional screens will appear. The first is a picture of the spectrum generated during the standardization. The second is a summary comparing factory set values for resolution, count rate, and peak positions to values calculated during the standardization.



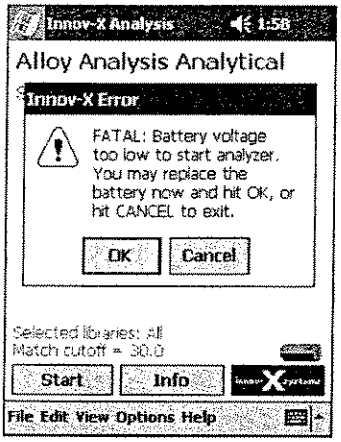
When standardization fails, verify that the standardization mask is in place, and attempt standardization again. To restandardize after a failure, tap the grey box in the center of the display, or choose ***File→Standardize***. If you are using a weld collimator, make sure that the solid part of the mask is covering the window.

If standardization fails again, exit the analysis screen and power off the instrument. Restart and restandardize. If the standardization fails a 3rd time, you will be prompted to perform a soft reset of the iPAQ. Selecting Yes on this screen will automatically soft reset the IPAQ. You should also power cycle the instrument. Restart and restandardize. If the standardization fails again, replace the battery in the instrument and attempt another standardization. If this fails, please contact the Innov-X Systems service center at **781-938-5005.**



4.4.3 Battery Replacement and Initialization/Standardization

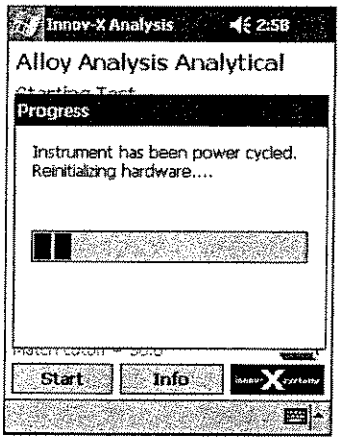
When the battery is too low to take a measurement, an error message will appear:



In order to continue testing, replace the battery immediately, and then tap "OK." The analysis screen will remain open, and the instrument will reinitialize. This process will take 1 minute. It is not necessary to re-standardize, provided that less than 4 hours has elapsed since the last standardization and the battery swap is completed within 10 minutes.

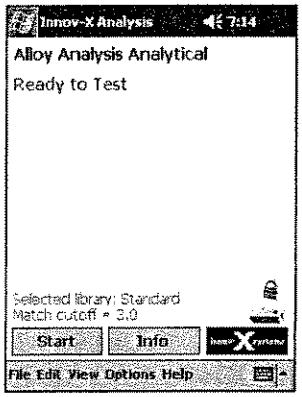
After re-initialization is completed, testing can continue.

If the battery is not replaced, and cancel is selected, the Analysis screen will close. When the software is restarted, the instrument will go through a complete 1 minute initialization and will require standardization.

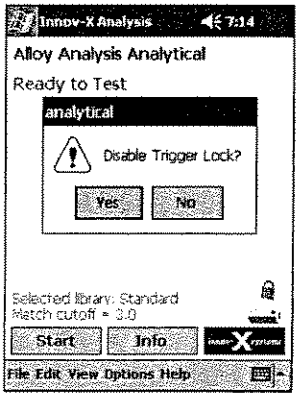


4.5 THE SOFTWARE TRIGGER LOCK

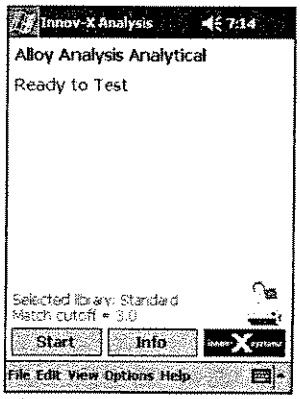
Innov-X analyzers are equipped with a software trigger lock which prevents the trigger from being actuated unintentionally. The lock is released by tapping an icon on the iPAQ screen. Once the lock is released, it will remain unlocked for subsequent tests, until more than five minutes has elapsed between tests. At that point, the trigger lock will be activated and will need to be disabled before additional testing can commence.



Tap the lock icon located directly above the battery indicator.



Select yes to disable the trigger lock



The open lock icon indicates when the trigger is disabled.

4.6 TEST INFORMATION - LABEL INPUT

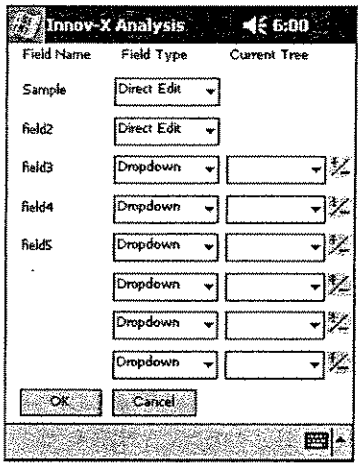
Information such as sample name, and identifying characteristics can be stored with each measurement. This is done from the test information (Test Info) screen which can be accessed from the **Analysis Screen** of any mode by tapping the **Info** button, or selecting ***Edit→Edit Test Information***.

The **Test Info** screen consists of eight fields. The name and format of each field can be changed by using the **Modify Test Info Template** feature described in section ***4.5.1* Modifying the Test Info Template**. The process of entering test information prior to each analysis is described in section **4.5.2 Entering Test Information**. Finally, the process of entering or changing test information after the analysis has been completed is described in section **4.6.3 Editing Test Info from the Results Screen**.

4.6.1 Modifying the Test Info Template

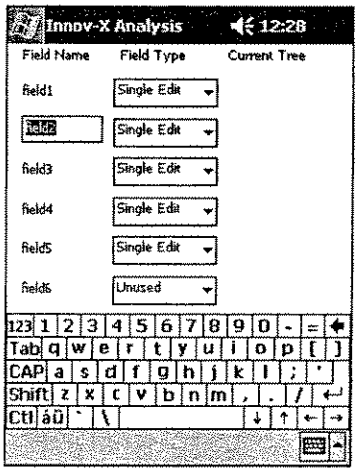
Test Info fields are modified via the Modify Test Info Template option found in the edit menu on the analysis screen in every software mode. Each field can be designated to be Direct Entry, Drop-down, or Tree. Direct entry fields allow users to enter characters directly from the virtual keyboard, or a bar code reader. Drop down menus provide a list of options to choose from. Trees are more complicated drop-downs; which allow users to subdivide large numbers of choices for ease in quickly locating the correct label. For example, a user may set up a tree with several parts for a main assembly. Subassemblies for the parts can be linked to their parent parts.

To make any changes to the Test Info format, select ***Edit →Modify Test Info Template*** from the analysis screen of any Mode. Modifications of Test Info screens are specific to each mode, and will need to be made to each mode if more than one is used.



4.6.1a Changing Field Names

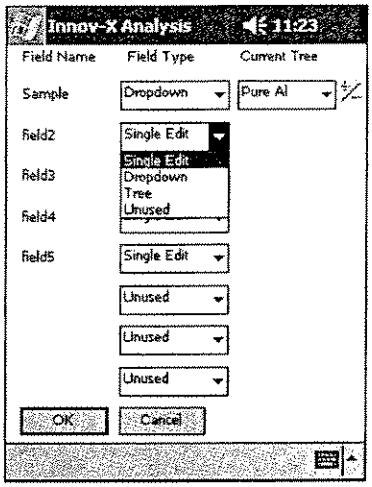
Field names can be edited by tapping on the current name. This will open an editable text box. A new name can be entered with the virtual keyboard. Selecting another cell or tapping **ok** will save this info.



4.6.1b Selecting Field Type

From the Modify Test Info screen, the type of field can be selected from a drop-down menu. Simply tap the arrow in the Field Type box for the field being modified.

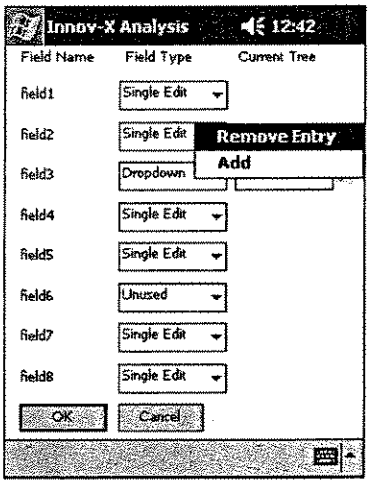
- Select **Direct Edit** for a text field which will accept data from the virtual keyboard, or a bar code scanner.
- Select **Drop-down** for a drop-down list
- Select **Tree** for a Drop-down menu with many choices, some of which may be grouped into categories and subcategories.
- Select **Unused** to eliminate the field from the Test Info screen.



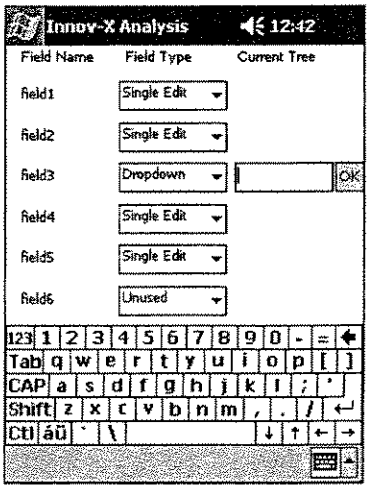
4.6.1c Changing Drop-down Menu Entries

Once a field has been designated a drop-down menu, entries can be added or deleted by clicking the +/- symbol to the right of the field. Two choices will appear; **Remove Entry** and **Add**.

To delete a drop-down entry, first select the label to be deleted, then press +/- and tap **Remove Entry**.

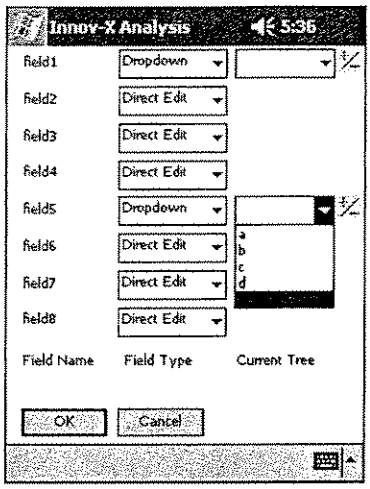


To add an entry from a drop-down list, tap the +/- symbol next to appropriate field, and select **Add**. Type the new info into the blank text box that appears. Select **OK** and the entry will be added to the drop-down menu.



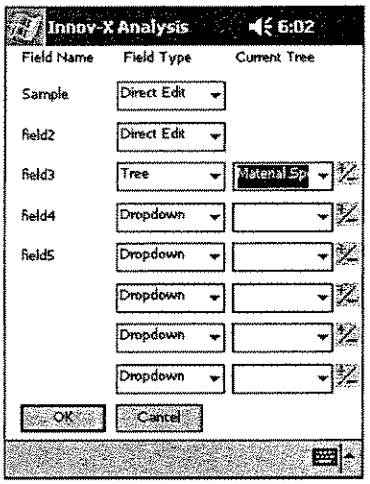
Repeat the process above to complete the complete drop-down list.

If it is anticipated that a drop-down field will not be used for all samples, enter an empty field as a choice so you can choose to leave the field blank.



4.6.1d Changing Tree lists.

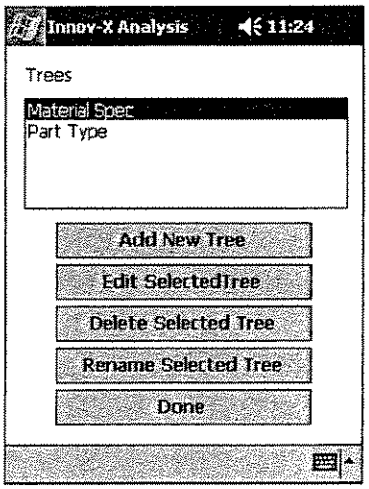
Once a field has been designated a tree, modifications to the contents of the tree can be made by tapping the +/- symbol to the right of the tree.



All modifications to trees are made from the menu shown on the right.

It is possible to add, edit, delete or rename trees. Select the appropriate choice from the menu to perform any of these functions.

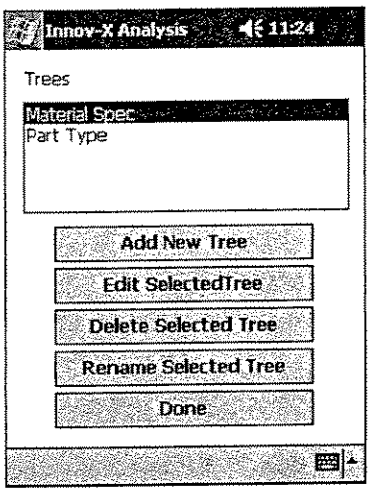
When you have finished creating/editing your tree, highlight it and select **Done.**



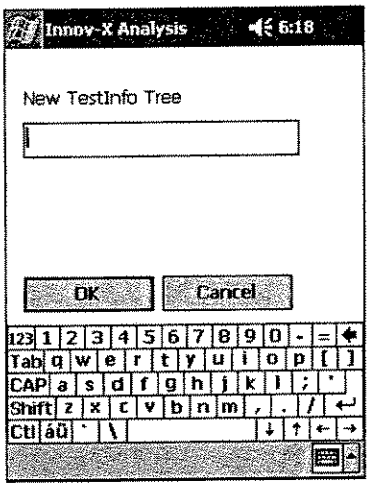
The following is an example of how a user might create a tree:
A manufacturer of tubes and valves tests all parts to ensure that they're made of the proper material. The company's QC procedure involves labeling each test with the part number of the item. Rather than forcing operators to look through a long list of part numbers, a tree is created in order to subdivide the parts number into groups based on part type.

The procedure for creating the tree is as follows:

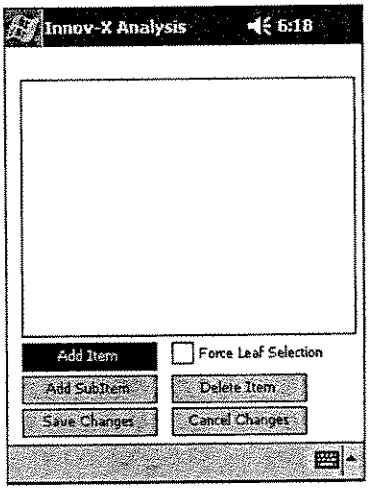
Select: Add New Tree:



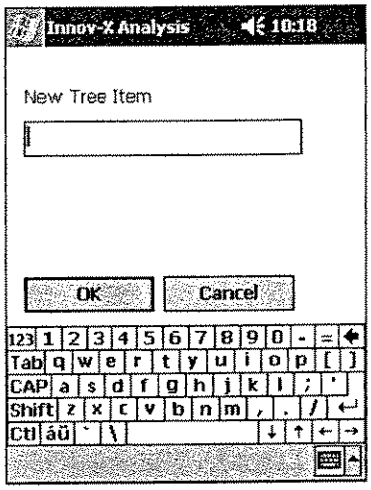
Enter the Name of the Tree in the text box and select OK.



Tap Add to add the first item

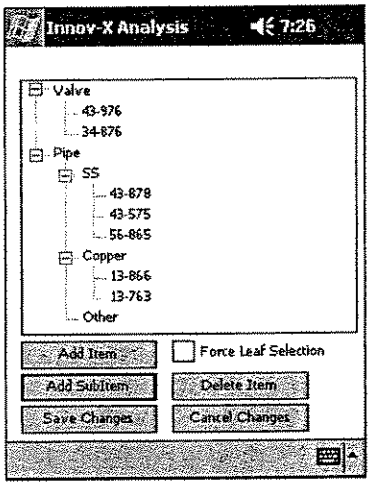


Enter the name of the item



Once the tree is started, continue to Tap Add Item to add a top level menu item, or select an item and tap Add SubItem to link a subcategory to the item. Continue until all items have been added.

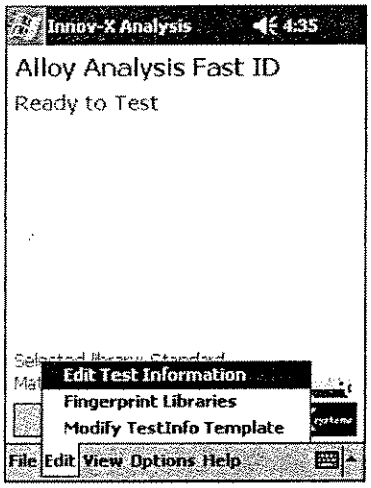
In this example, the part numbers for pipes and valves are separated into categories. The pipes are further subdivided by material type.



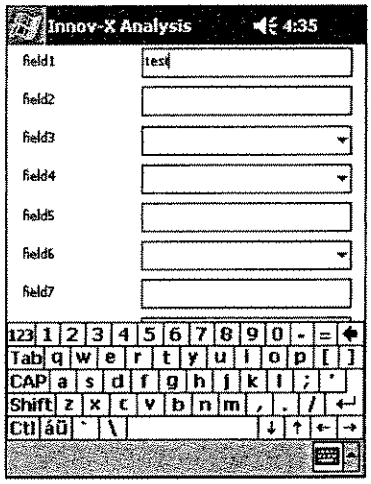
Clicking the "Force Leaf Selection" will require that the user select a bottom level menu item, (in this case, a part number.) If Force Leaf Selection is not checked, users may choose any field included in a tree, including category labels, such as Valve or Pipe in this example.

4.6.2 Entering Test Information

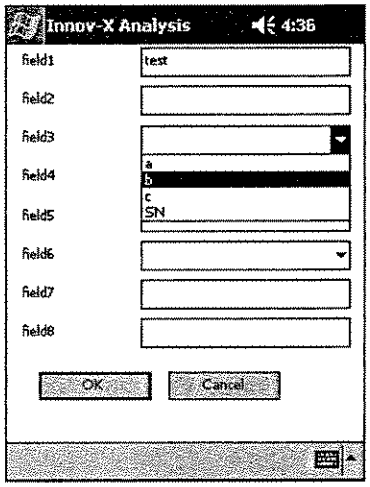
1. To enter the Test Info screen, you must be in the Analysis Screen. If the Results Screen is open, tap the ⊗ in the upper right hand corner to return to the Analysis Screen. From the Analysis Screen, select ***Edit→Edit Test Information,*** or tap the **Info** icon.



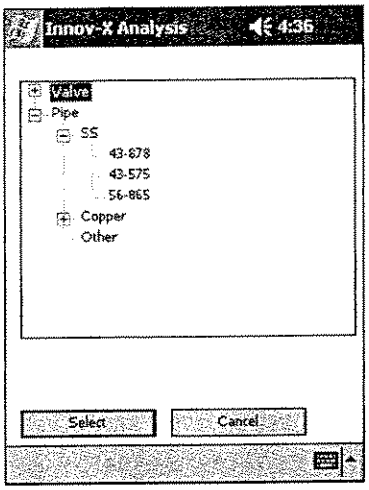
2. To enter a unique sample name or number, select a direct entry field by tapping anywhere within the field. Use the virtual keyboard to enter the information.



3. To select information from one of the drop-down menus, tap the arrow to the right of the box. Select the desired entry.



4. Some drop-down fields are formatted as trees. To select information from these fields, tap the arrow to the right of the box. A screen will appear showing options. The plus (+) symbol will appear before some choices indicating the presence of sub-items. Tap on the + symbol to expand the menu. Tap on any item or sub-item to select it, then press **Select**.

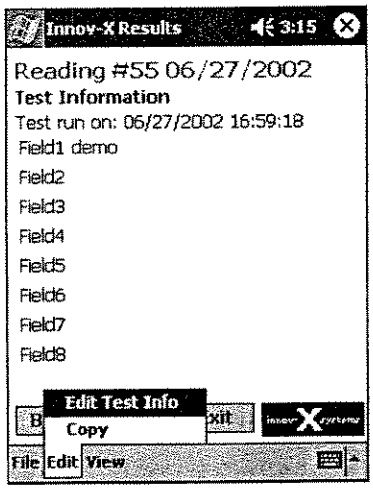


5. When all the necessary data have been entered. select OK
6. The information entered in the test info screen will be saved with each reading until the test info screen is modified again.

4.6.3 Editing Test Info from the results screen

Test information can be edited, or added to a test after its completion.

- From the results screen, scroll to the reading to be modified.
- Select ***View →Test Info*** to see in the information which is already stored.
- Select ***Edit → Edit Test Info*** to bring up the editing menu.



You will then be presented with the same test information screen described in **Section 4.5.2: Entering Test Information.**

4.7 EXPORTING AND ERASING DATA

Because the memory of the iPAQ is limited, you should periodically backup the data on your analyzer, and erase the memory. Depending on test volume, it is recommended that all data is erased on a weekly or monthly basis.

4.7.1 Installing ActiveSync

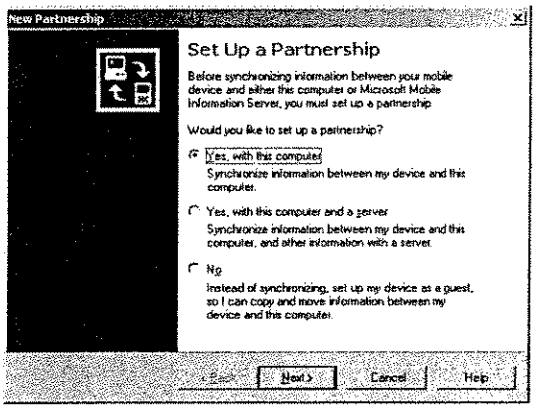
In order to copy files between the iPAQ and a desktop PC, Microsoft Active Sync Software must be installed on the desktop PC. Innov-X strongly recommends that you download the latest version of ActiveSync from the internet. ActiveSync v3.7 may be downloaded from http://www.microsoft.com/windowsmobile/resources/downloads/pocketpc/activesync37.mspx

If it is not possible to download the latest version, an ActiveSync CD (v3.5) was shipped with your analyzer. Check behind the foam in the instrument case.

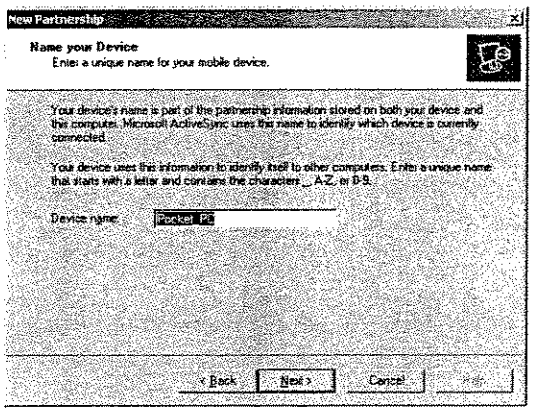
The iPAQ cradle should be hooked up to the USB port on the desktop computer before installing software.

The Procedure for installing and setting up ActiveSync is as follows:

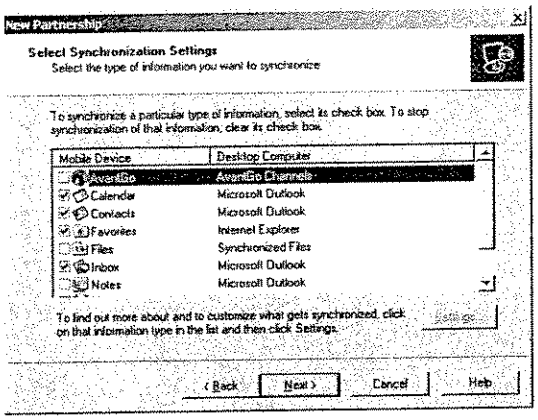
1. Insert the ActiveSync CD in your CD Drive. It will start automatically. The CD contains information about Getting Started with Your Pocket PC. This changes periodically, so it's difficult to describe exactly what the screens will look like. Step through the screens until you see the option "Install ActiveSync." Select this to start the installation process.
2. Follow the prompts on the screen. When given the choice, select "Run this program from its current location" and click OK.
3. Complete the install process. You will be required to restart your computer in order to complete the installation.
4. After restarting your computer, dock the iPAQ in the cradle. The iPAQ should automatically communicate with your computer. If it doesn't, check the connections and try removing the iPAQ and reseating it. If that doesn't work, try doing a soft reset on the iPAQ
5. When the computer communicates, you will be prompted to "Set Up a Partnership." Select "Yes, with this computer"



6. Enter a name for your iPAQ and click next.



7. You will be prompted to "Select Synchronization Settings." **Select "Files" only.** ***It is important to make sure that*** **Files** ***is the only item checked. Otherwise, the files such as address books and emails will be copied from the desktop computer to the iPAQ.***



8. Step through the rest of the process.

9. A folder will automatically be created on the PC's desktop with the name of the device entered in step 8 above. Results files saved on the iPAQ will automatically be synched and will be stored in this folder. Opening this folder and clicking on the name of the file will open the file in Excel.

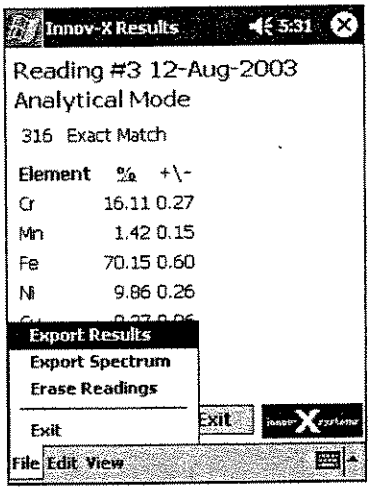
10. After ActiveSync is set up correctly, copying results to a desktop computer will consist of
    a. Exporting results on the iPAQ. (described in section 4.6.2)
    b. Synching the iPAQ to the computer
    c. Opening the results in Excel for viewing, or printing.

4.7.2 Exporting Results

All data from your Innov-X Systems analyzer can be exported as a comma delimited text file (csv). This format allows the data to be easily exported to spreadsheet programs. It is possible to export all data from a single day, or to export all data saved in the iPAQ. Results and spectra are exported separately.

To export or erase data, you must be in the Results Screen. This is automatically opened when a reading is taken, or can be accessed by choosing ***View→Results*** from any analysis screen.

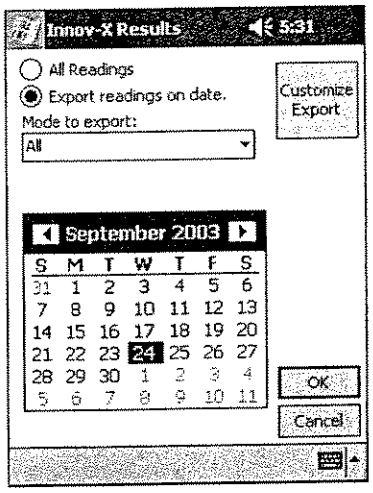
From the results screen, select ***File→Export Results***



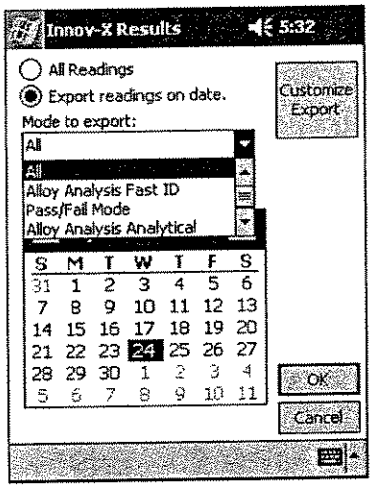
You can choose to export All Readings or just Readings on a specific date. Choosing **All Readings**: will export all readings saved in memory and is a good choice if you want to backup all data stored on the instrument before deleting. If a large number of readings stored, this option will take several minutes.

Choosing **Export Readings on date** requires that you pick a date from the calendar below. It is strongly recommended that you use this option and export data on a daily basis.

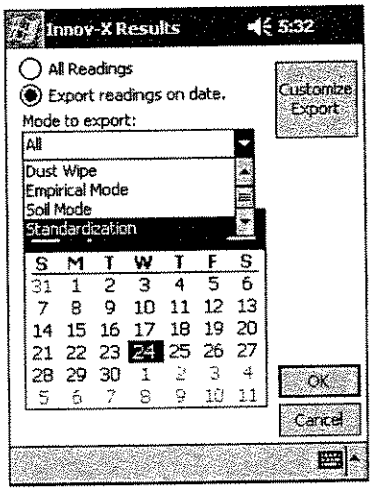
The customize export option allows users with administrative password privileges to customize the format in which data is exported. This is described in **Section 4.6.3: Customizing Results Export**.



After choosing which readings to export, you may choose to export all data, or just data from a specific mode. Selecting the arrow to the right of the mode to export will open a drop-down menu. Select the mode for which you want to export data.

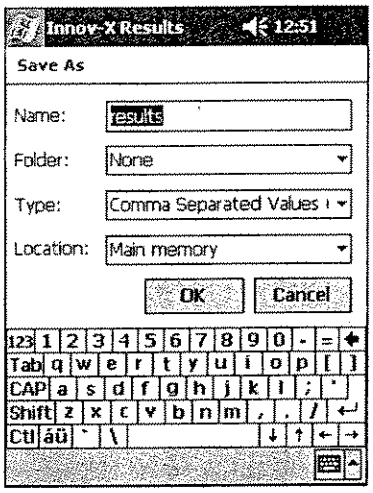


All standardization data are stored as results files. These data are automatically included in exported results files when the selected "Mode to export" is **All.** Additionally, it is possible to export only the standardization data by selecting **Standardization** as the "Mode to export."

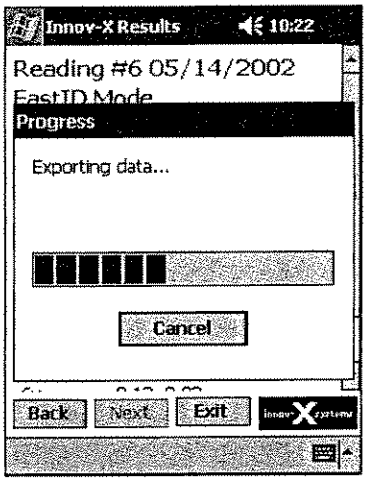


When the proper selections have been made, select **OK**. A **Save As** box will appear. Select the folder in which you want to save the data, and name the file. The file Type will always be **Comma Separated Values**. The recommended Location is Main memory and Folder is **None.** This will export files into the "My Documents" folder in the main Memory of the iPAQ.

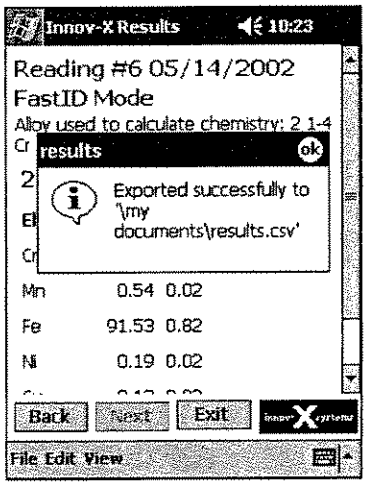
If you select a File Name which already exists, you will be asked if you want to replace the existing file. If you do, select **Yes**. Otherwise select **No** and choose another file name.



A status bar will indicate the progress of the export. It may take several minutes to export many readings. Daily downloading and weekly erasing of data simplifies and shortens this procedure.



When all readings are exported, a message will appear confirming the export. Tap **ok** to acknowledge and clear the reading.



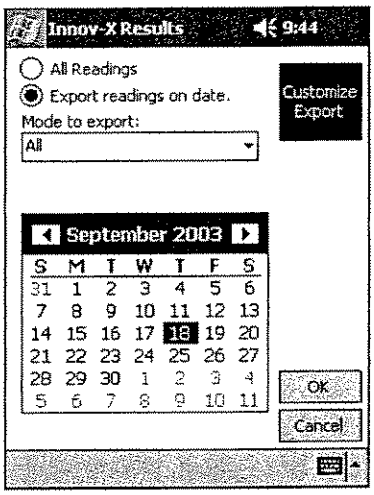
4.7.3 Customizing Results Export

All units come with a standard results export format which reports a variety of information relevant to a test. Users can select which fields are exported as well as modify the order.

To modify exported results files, select **File →Export Readings** from the Results screen.

Tap the **Customize Export** box.

Enter the administrative level password when prompted.



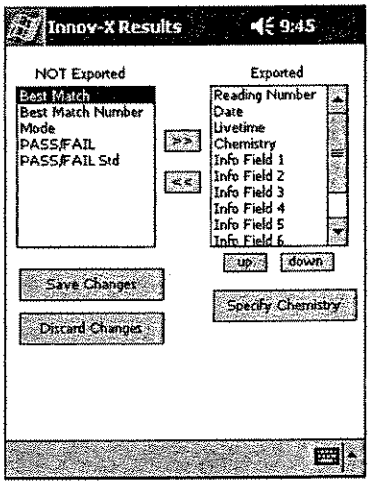
Two columns appear on the screen; the column on the left lists fields which will NOT be exported, and the right-hand column lists fields which will be exported.

Fields can be moved from one column to another via the >> and << buttons located in the center of the screen

Exported field order can be changed by using the **Up/Down** buttons. Select a field and move it up or down as desired

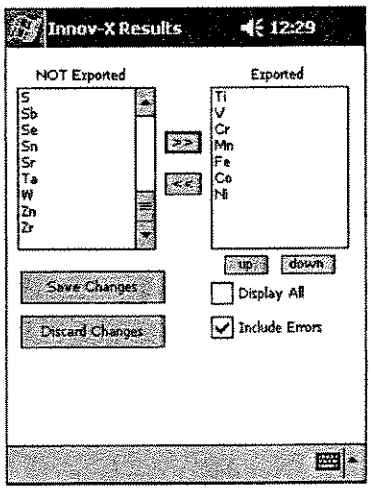
Once all changes have been made, choose **Specify Chemistry** if changes need to be made to the list of exported elements.

In chemistry is not edited, select **Save Changes** to keep the modified settings, or **Discard Changes** to ignore any changes.



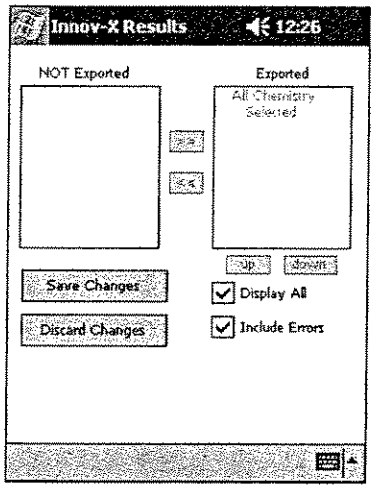
The Specify Chemistry screen resembles the previous screen. Move elements to the appropriate column, depending on whether or not an element should appear in exported files.

Select **Include Errors** to export the error associated with each measurement.



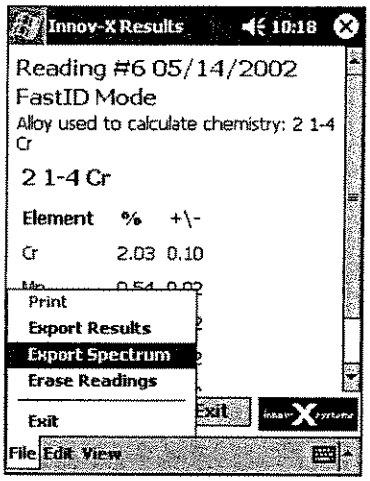
Select **Display All** to include all measured elements. *This setting is recommended, as it will ensure that all data measured with the instrument is exported.*

When all changes have been made, tap **Save Changes** or **Discard changes,** depending on whether the changes should be saved.

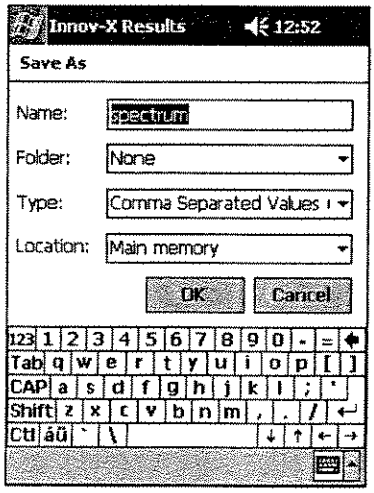


4.7.4 Exporting spectra

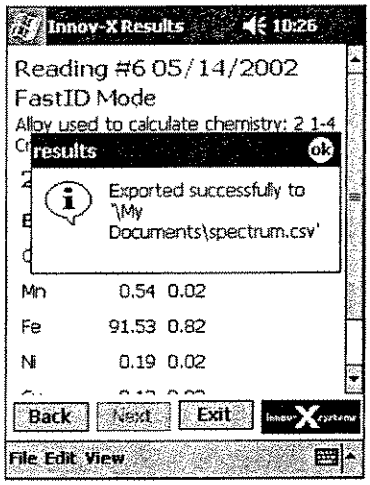
Only one spectrum may be exported at a time. In the results screen, scroll to the reading for which you wish to export the spectrum, and ***Select File→Export Spectrum.***



Choose the File name, and make sure that **Comma Separated Values** and **Main Memory** are selected. This will save the spectrum to the My Documents folder in the Main Memory of the iPAQ.



A message will appear indicating a successful export. Tap **ok** to acknowledge and clear the window.



4.7.5 Erasing readings

It is possible to erase a single reading, a range of readings, all readings from a specific data, or all readings before a specific date.

In order to erase a single reading, the reading to be erased must displayed on the screen before selecting delete. If necessary scroll to the reading you wish to delete.

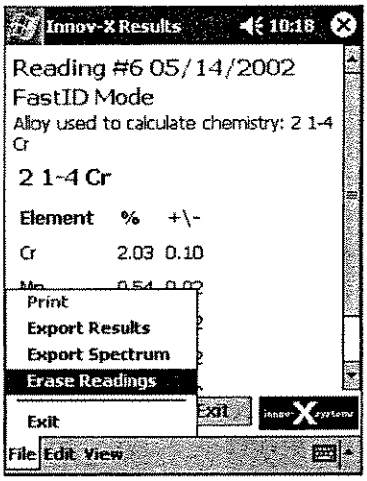
In order to select a range of readings, you must have a reading open from the date you wish to delete the readings. If a reading from the desired date is not open, you may select ***View→Go to date***, and select the appropriate date.

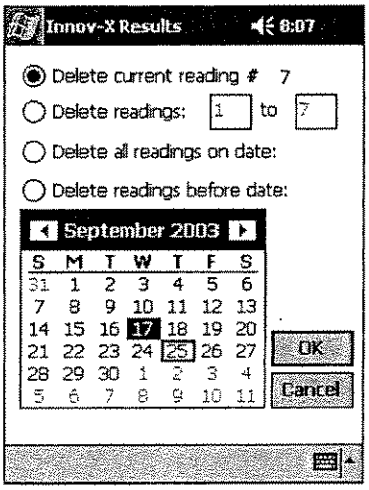
The reading displayed in the results screen is not relevant if you want to delete all readings from a specific date, or all readings before a specific date .

From the results screen, select ***File→Erase Readings.***

A message box will appear prompting you to enter your password.

Enter your administrative level password and select **OK**.





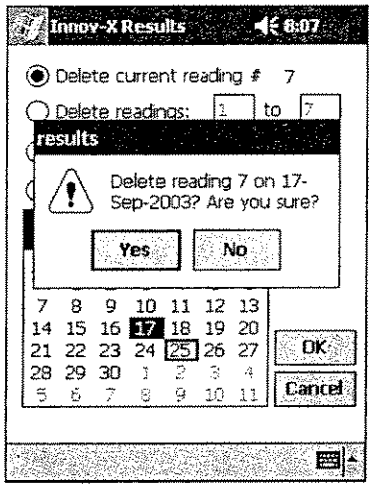
A dialogue box will appear allowing a choice of which results to delete. Select the appropriate choice:

- Selecting **Delete current reading** will delete the reading that is currently open.
- Choosing **Delete readings XX to XX** will delete a range of readings from the date of the reading that is currently open.
- **Delete all readings on date** deletes all readings from a specific day.
- **Delete readings before date** deletes all readings taken prior to a specific day.

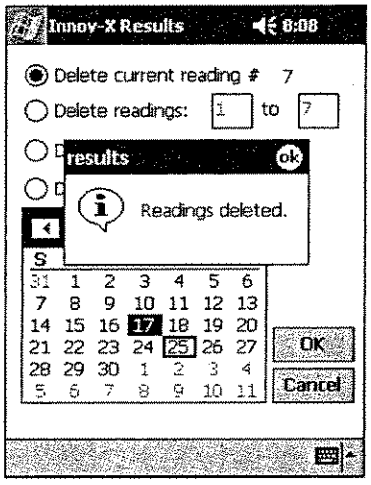
If you select **Delete all readings on date** or **Delete readings before date**, you must specify a date from the calendar. The default date is

the current date.

When you've selected the readings to delete, Click **OK**. You will be asked if you're sure you want to proceed. If you want to proceed with the data erase, select **Yes**. Otherwise, click **No.**



A message will indicate the readings were successfully deleted. Tap **ok** to acknowledge and clear the message window.



5.0 ALLOY ANALYSIS

5.0 ALLOY ANALYSIS INTRODUCTION

Three different modes exist for the analysis of alloys:

- **FastID Mode**
- **Pass/Fail Mode**
- **Analytical Mode**

Standard systems are equipped with all three modes; however, others may have only one or two available. Instruments can be upgraded for a fee at any point after purchase. General introductions to each of the modes, as well as basic operations are found in this chapter. Subsequent chapters describe each of the modes in greater detail.

FastID MODE

FastID mode is designed to quickly identify an alloy by matching the spectral signature of an unknown sample to the saved spectral signatures of reference standards in the FastID library. This mode can provide alloy chemistry if concentration data are entered for the standards. Chemistry results are a linear extrapolation from standard intensity data. FastID Mode is suited for determining accurate chemistry for alloys for which standards are available AND are loaded into the library. A standard library, as well as 3 user libraries can be used for matching. All libraries can be edited.

PASS/FAIL MODE

Pass/Fail mode is used to quickly test alloys to ensure that they meet quality control criteria. The operator chooses a stored spectral fingerprint which the system uses as a reference standard. Samples are compared to the reference, and a Pass or Fail result is displayed. Pass/Fail decision criteria can be spectral signature matching or concentration ranges for one or more elements. Pass/Fail mode uses the same fingerprint library as FastID mode.

ANALYTICAL MODE

Analytical Mode provides a full analysis of alloy chemistry using the method of fundamental parameters, as well as a grade match based on minimum and maximum grade specifications. This method uses a factory calibration, and requires no additional user supplied standards. In addition using the comprehensive grade library included with the analyzer, users may enter additional grade table specifications.

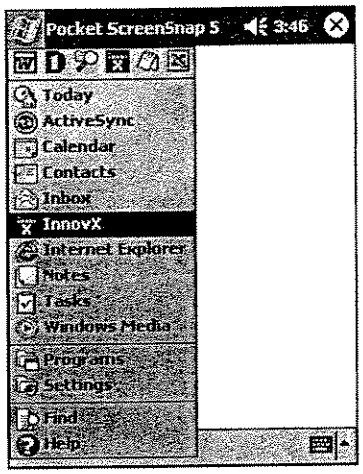
5.1 ALLOY ANALYSIS – STARTING THE INSTRUMENT AND TAKING A MEASUREMENT USING THE STANDARD LIBRARY

The basic startup and testing procedure is described below. Most screen shots were taken using **FastID Mode**; however, the basic procedure is the same for all three alloy modes.

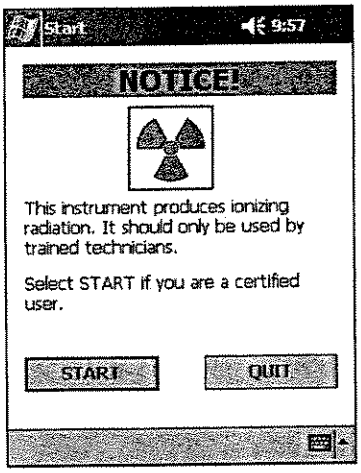
BASIC OPERATION

All Innov-X Systems Analyzers are shipped with a standard set of reference alloy standards that makes it possible to identify approximately 200 common alloys (35 in FastID). A list of the references in the library is provided in Appendix III. When you first receive your analyzer, it is recommended that you start by analyzing the 316 standardization piece included with your analyzer to gain an understanding of how the analyzer works.

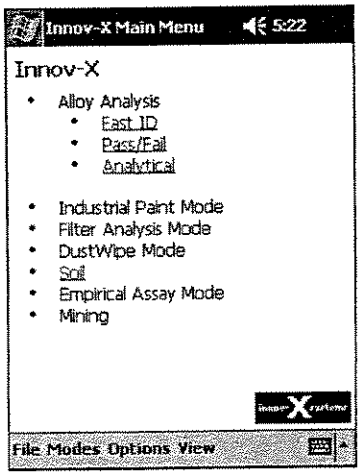
1. Install a freshly charged battery in the instrument.
2. Turn on the analyzer by pressing the power switch located on the base of the instrument.
3. Verify that the iPAQ is correctly seated on the top of the unit. If the iPAQ is properly connected, the amber light on the upper right side of the iPAQ next to the power button will blink, indicating that the iPAQ is receiving charge from the analyzer.
4. If the iPAQ is not on, turn it on by pressing the power button on the upper right side of the iPAQ.
5. Start the Innov-X Systems Software by selecting the Start Menu from the upper left hand corner of the iPAQ screen. Select the Innov-X Systems Software from the drop down menu.



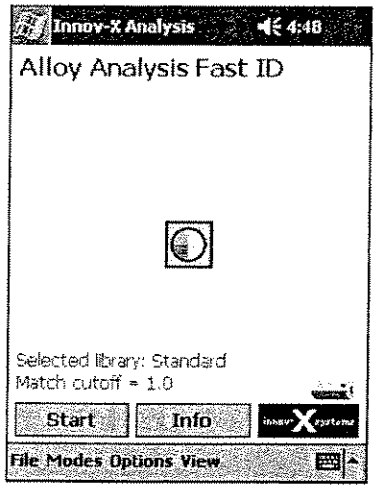
6. A notice will appear reminding the user that this instrument produces ionizing radiation and requires a trained user. . Select **START** to start the Innov-X Systems Software package. Selecting **QUIT** will exit the Innov-X Software.



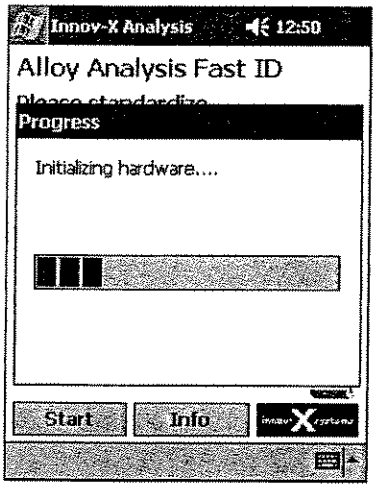
7. The Main Menu will open. Tap the name of the Mode you will be using to open it. First time users should Analytical Mode.



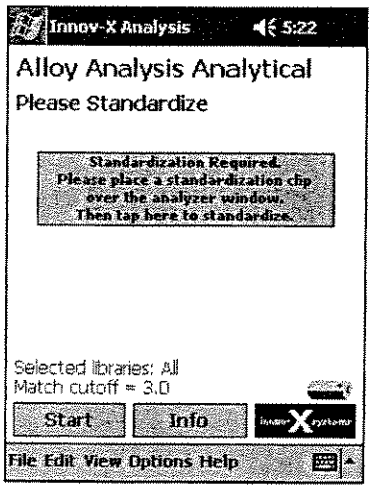
8. There may be a brief pause while the instrument loads the various parameters needed for operation. While this occurs, an icon will appear in the center of the iPAQ screen.



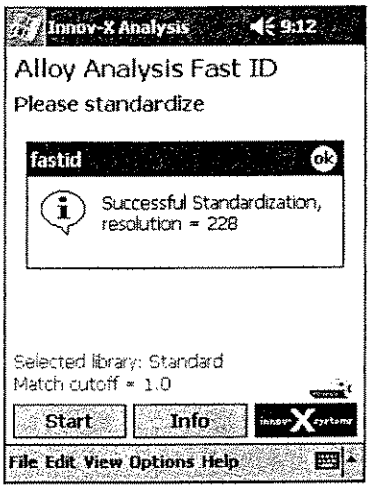
9. Once the analysis mode has been selected, the instrument will go through a 1 minute hardware initiation during which the electronics will stabilize and the detector cooling will be initialized.



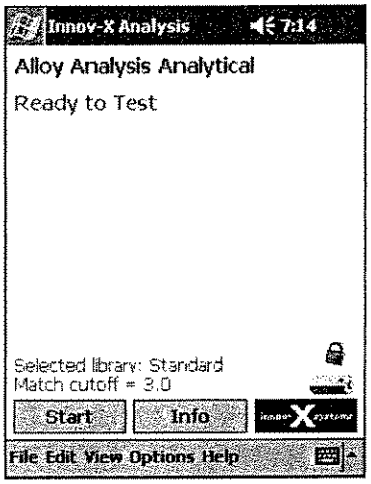
10. The message "**Standardization Required. Please place a standardization clip over the analyzer window. Then tap here to standardize.**" will appear. Standardization is required before testing can begin. Place the standardization clip in front of the analyzer window. Tap the message box. Standardization will take approximately 1 minute; a status bar will be displayed throughout the measurement. Standardization is described in more detail in **Section 4.4: Standardization**.



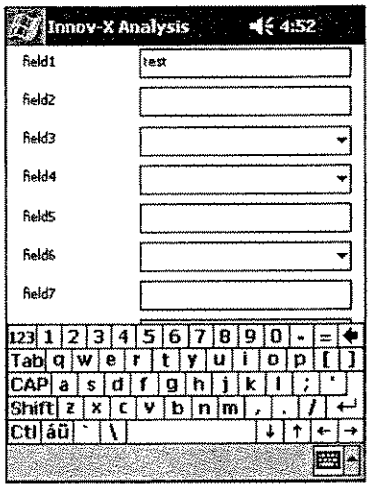
11. When standardization is complete, the resolution of the analyzer will be displayed. Tap **ok** to acknowledge and clear this screen.



12. The analyzer is now ready to take a measurement. The Trigger lock must be unlocked before pulling the trigger will start a test.



13. If you wish to enter a sample name or sample identifying characteristics, select ***Edit→Test Info***. Enter information in text fields, or select items from drop down menus. Select **ok** to close the Test Info window. The format of this screen may vary depending on user settings. See **Section 4.5: Test Information** for more information.

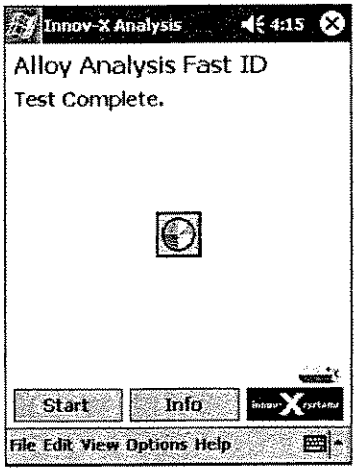


14. Hold the analyzer to the sample to be analyzed. Make sure the sample is as flush against the analyzing window as is possible. You may start an analysis by pulling and holding the trigger. Releasing the trigger will abort the test.

    a. After an analysis is started, the message "**Test in Progress.**" will appear, followed by the number of seconds elapsed during the measurement. For the duration of the test, the red light on top of the instrument will blink, and the "testing" icon will appear in the lower right corner of the IPAQ.

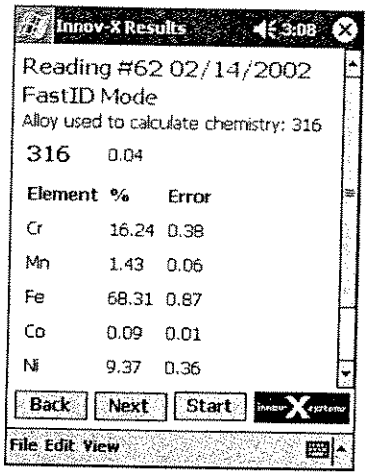
    b. When the measurement is complete, the analysis screen will display the word **Calculating**. There may be a slight delay while the instrument calculates the results. This will be indicated by the appearance of a "calculating" icon in the lower right hand corner of the iPAQ screen. Because the FastID calculation is very rapid, this icon is rarely seen, however there may be a few second calculation for Analytical Mode.

    c. When the calculations are complete, there will be a slight delay the first time the results screen is opened. An icon will appear in the center of the screen during this delay. This indicates that the results program is loading and re-indexing all saved results.



15. The Results screen will display the results. The information displayed on the screen may be changed by selecting one of the options under the View menu. This is described later in this chapter under the Results section. If you analyzed the standardization piece, the grade identification should be listed as 316.

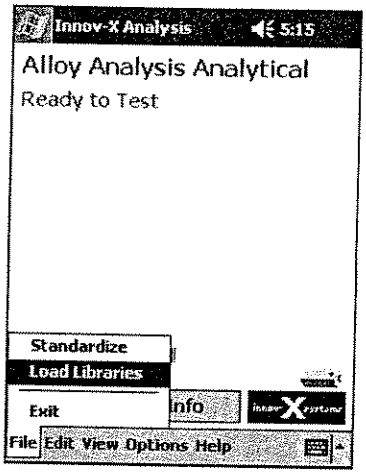
16. Once the results screen is open, subsequent readings may be started by depressing the trigger. If at any point, you wish to return to the analysis screen, select ***File→Exit*** or tap the X in the upper right hand corner of the screen.



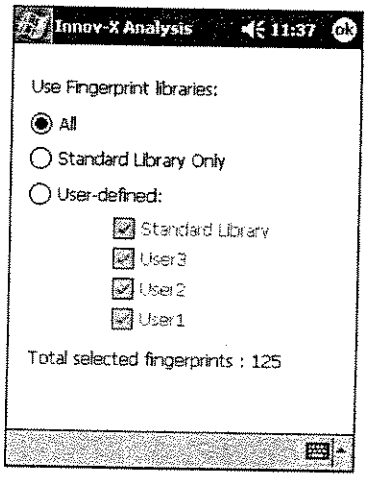
5.2 SELECTING A LIBRARY

The Innov-X Software can search any one of four libraries when in **FastID** or **Analytical Modes**. **ALWAYS VERIFY THAT THE CORRECT LIBRARY IS BEING SEARCHED.** More detailed information on library functions can be found in Chapter 5.

To select which library to search, go to the **FastID** Analysis Screen or the **Analytical** Analysis Screen – whichever mode is in use – then select ***File→Load Libraries*** .



A menu appears. The first line will read **Use Grade Libraries** for Analytical Mode and **Use Fingerprints** for FastID Mode

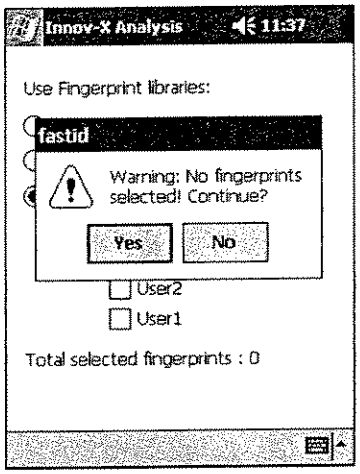


Choose the Fingerprint or Grade Libraries you wish to search. For the most comprehensive search, select **All** libraries. This will search the entire Standard Library, as well as any fingerprints or grades that have been added by the user.

Users who are primarily concerned with sorting the most common specialty, stainless, nickel and high temperature alloys should always search the **Standard Library**. This will ensure that the factory-installed library will be searched. The Standard Library can be searched by itself, or in combination with any of the other libraries.

Users who are sorting a small group of alloys may prefer to create their own libraries using their own standards. In this case, only the appropriate user library should be selected.

When loading libraries from the ***File→Load Libraries*** Menu, the number of fingerprints or grades in the selected libraries is displayed at the bottom of the screen. For best results especially when measuring complete unknowns, a large number of fingerprints should be selected because the analyzer cannot identify an alloy that is not in a library.



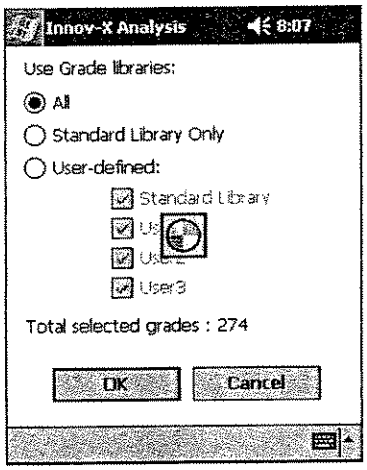
Since there is a good chance that searching a small number of libraries will result in No Matches, a warning message will appear if you select 10 or fewer grades or fingerprints.

Select **No** to return back to the Use Fingerprint Libraries screen to make another selection.

Select **Yes** to continue with the selected library. Keep in mind that with fewer fingerprints or grades being searched, you will likely get a larger number of No Matches.

If no fingerprints are selected, it will not be possible to get any valid results in FastID. If a user continues with no fingerprints selected, it will be necessary to teach fingerprints in the selected library before proceeding with the analysis. In Analytical Mode, chemistry will be calculated, but no grade matches will be displayed if no grades are loaded.

There will often be a pause of several seconds while the instrument loads the new libraries. A revolving icon will appear in the center of the screen indicating that the libraries are loading.



5.3 SETTING THE ANALYSIS TIME

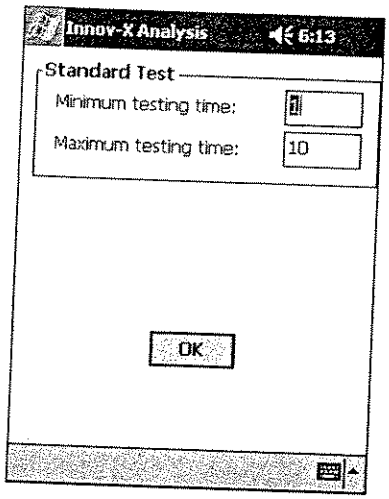
The software allows the user to set up minimum and maximum testing times.

The minimum testing time must elapse in order for results to be calculated. If a test is stopped before the minimum testing time, it will be treated as an aborted test, and no results will be calculated. Additionally, if the Live Update feature described in section 5.4 is active, results will not be displayed on the screen until after the minimum time period.

The test will end automatically when the maximum testing time is reached. A test can be ended manually at any time by releasing the trigger.

To change Testing times:

From any analysis screen, select ***Options→Set Testing Times***



Typical settings for standard test times, in seconds are:
Minimum testing time: 3
Maximum testing time: 10.
However, these values may be changed depending on the application and the desired results.

Alloy system equipped with Analytical ***Smartbeam*** will have an option for setting the test time in this screen as well. ***Smartbeam*** is discussed in chapter 8.

The minimum testing time is required to be no less than 1 second. An error message will appear if the time is set to be less than 1 second. Clear this message by selecting **ok**. The time will default to a minimum time of 1 second. This value may be used, or another value may be entered. Select **OK** to close the window.

You will not be allowed to exit the **Set Testing Times** window unless a valid minimum testing time has been entered.

Recommended Testing Times:

For most alloys, the recommended testing time is 5-10 seconds to obtain a unique grade ID and good alloy chemistry. For some alloys that only differ by small amounts of one or two elements, it may be necessary to perform longer tests. Examples include Low alloy steels 4140 and 4340. Alloys which differ by less than 1% of Ti or V require the optional ***Smartbeam*** feature for quick separation.

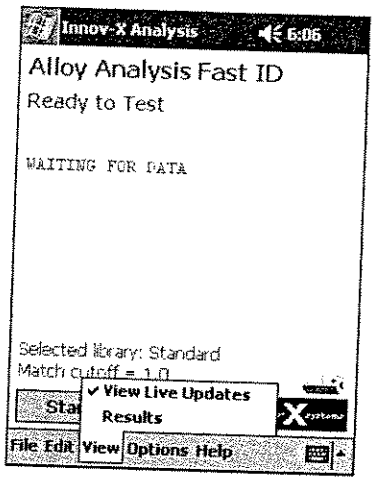
The maximum testing time will determine the length of a test. The analysis will automatically stop if the maximum testing time is reached. Normal maximum testing times will range from 5 to 20 seconds. Fundamentally, if the goal of the analysis is primarily grade identification, shorter analysis times are used. If greater precision is required in the calculation of chemistry or if an alloy separation is particularly difficult, longer test times may be used.

It should be noted that the pre-set time refers to the length of time the analyzer is actively collecting data from the detector. The total analysis time can be slightly longer than the maximum test time due to the small amount of time required to process the data and calculate the results.

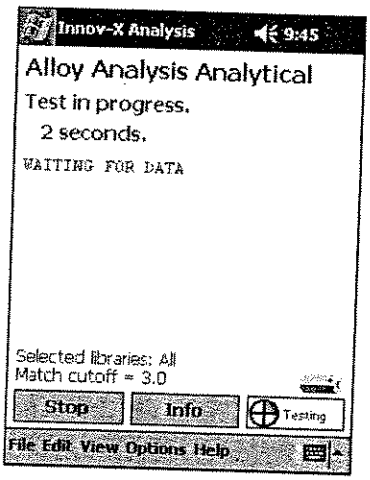
5.4 LIVE UPDATE DISPLAY

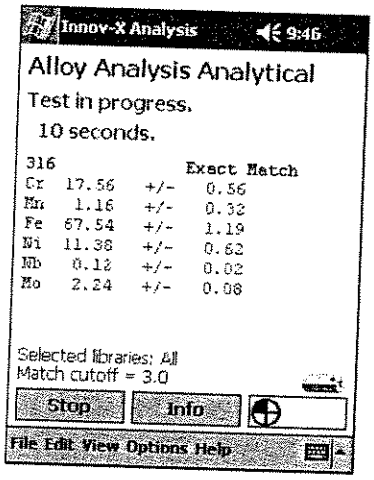
In addition to viewing completed tests in the results screen, the analyzer will display screen updates as the results are calculated during a test. This allows users to decide when to stop tests based on the precision of the reading.

To switch Live Updates on or off, select ***View→Live Updates***. A check mark will indicate if Live Updates are turned on.



When the Live Updates feature is on, and a test is in progress, the screen will show the message "WAITING FOR DATA" until the minimum testing time set in ***Options → Set Testing Times*** has elapsed. After that, chemistry and the errors on the chemistry will be displayed. This feature allows the user to stop the test as soon as the desired precision is reached.





If too short a maximum test time is set, the test may end before the desired precision is reached. As a result, some users who prefer to end tests based on the screen display may choose to set long maximum test times (60 seconds or so) and manually end all tests.

5.5 SAMPLE CONSIDERATIONS

5.5.1 Coated or Painted Samples

Innov-X Alloy Analyzers are capable of analyzing a wide variety of sample shapes and types. However, it is important to understand that XRF is fundamentally a surface analysis technique. X-rays penetrate a very short distance into most alloy samples. Therefore, the analyzer will detect what is on the surface of an alloy, rather than what comprises the bulk of the material. If a material has been coated, plated, painted, or has had some sort of surface treatment, such as heat treating, it may be misidentified. For example, a steel piece that has been painted grey will show high concentrations of titanium from the paint, and may be misidentified as a titanium alloy. In addition, large amounts of metal dust or turnings on a surface may be detected by the analyzer.

To ensure proper identification of coated materials, an area slightly larger than the analyzing window should be should be ground to remove the coating. This will allow the analyzer to measure the alloy rather than the coating. It is not necessary to completely clean and polish all materials, however, obvious metal dust should be removed.

5.5.2 Mixed samples, Heterogeneous materials

Often finished metal pieces may consist of more than one type of metal. In addition, some users may wish to measure mixed turnings, or an assortment of small pieces. In these cases, the user should remember that the analyzer will measure the entire area covered by the analyzing window and report an average chemistry. For turnings, this is useful, as the analyzer will provided an average composition. However, if two or more pieces of metal cover the window, the results will also be just an average reading, and may tell very little about the composition of one piece or the other. When shooting metal pieces, or welds, it is important to make sure that only the metal of interest is covering the analyzing window. It may be possible to use a welding mask to narrow in on the area of interest.

Keep in mind, that a welding mask should only be used in Analytical mode, unless fingerprints have been taught in FastID using the mask.

5.5.3 Small and irregularly shaped samples

All Innov-X Systems alloy software modes are able to measure parts that are smaller than the analyzing window; however, it is usually necessary to increase the testing time. The precision on measurements of small parts is reduced; since the signal from smaller samples is less then it is for samples that completely cover the window. It is also a good idea to try to maximize the material in contact with the window. If possible, analyze the largest flattest side of an irregularly shaped object.

5.5.4 Invisible elements

Since the Innov-X Systems Alloy Analyzer cannot directly analyze light elements such as carbon, aluminum and silicon, samples containing large amounts of these elements may not read correctly in Analytical Mode, depending on certain instrument settings. These settings are described in **Section 8.8.3: Light Element Analysis**.

Please read this section and familiarize yourself with the issues pertaining to Light Element analysis before attempting to analyze Aluminum alloys or other alloys containing significant amounts of non-detectable elements.

6.0A Alloy Analysis—FastID Mode

6.0 INTRODUCTION TO FastID MODE

FastID mode is designed to quickly identify an alloy by comparing and matching the spectral signature of an unknown sample to spectral signatures of reference standards stored in a library. This mode can provide alloy chemistry if concentration data is entered for the standards. These chemistry data are a linear extrapolation from standard intensity data.

The system is typically shipped with a library of approximately 35 stored spectral "fingerprint" reference standards and chemical assays for these standards. Some systems may be shipped with additional fingerprints, or with no fingerprints, depending on the details of the order. To identify one of the alloys contained in the standard library, no user calibration or input is required. The operator simply tests a sample, and the instrument determines the correct alloy grade by matching to the library of spectral fingerprints. The instrument then calculates the chemistry by using the stored elemental assays using the identified grade as a reference standard. The user may easily add up to 300 additional reference standards and assays if desired.

Warning: Because **FastID** Mode performs a spectral match to a library of reference standards, it is very important that a stored reference standard be in the FastID library that is being searched. For this reason, this mode is best suited for alloy verification, where in general the operator is checking that the alloy is the expected type. Thus, the operator can assure before commencing testing that a reference standard for that alloy is in the library.

FastID is ideal for most PMI, in-service PMI and QA/QC applications. This mode offers the best combination of speed and precision. By matching the sample spectra to a stored spectrum from a certified standard, the analyzer is able to make its chemistry calculation based on a calibration file created especially for the matching grade. This spectral matching technique offers the best combination of speed and accuracy. Some of the advantages of **FastID** mode include:

- Provides a grade and chemistry in as little as 5 seconds. This is the best precision for shortest test time, when compared to other modes. Matching the sample's spectral fingerprint first allows FastID to select from hundreds of certified spectra and use the single best set of calibration data for that sample. The benefit is the fastest AND most precise chemistry calculation.
- Operator may add up to 300 additional alloy grades and assays (alloy chemistries) — password protected.
- Instrument offers 3 separate grade libraries for multiple users, or multiple departments. User can choose to search one or more libraries.

6.1 ANALYZING A SAMPLE

Once the instrument is standardized (see **Section 4.4: Standardization**), your analyzer is ready for routine measurement.

1. Hold the analyzer up to the sample to be tested. Make sure the part of the sample you wish to analyze is in contact with the window on the front of the probe.
2. Unlock the trigger by tapping on the icon located on the iPAQ Screen directly above the battery indicator. Select Yes when prompted.
3. Pull the trigger to start the measurement. The trigger must remain depressed for the duration of the test.
4. While the analysis is in progress, the red LED on top of the instrument will blink, the amber light on the back of the instrument will glow, and the screen will display **Test in Progress**. In addition a "testing" icon will appear in the lower right hand corner of the iPAQ screen. All these indicators

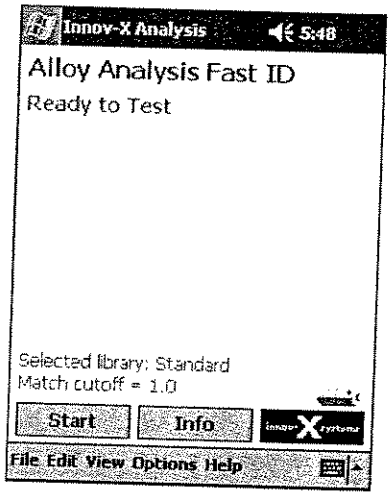
show that the X-ray tube is energized and the shutter is open. During the testing time, it is important to keep the analyzer flush with the sample surface.

5. A test can be aborted at any time by releasing the trigger.
6. Once the measurement is complete, the results screen will automatically open. The results will be displayed in one of three forms, depending on the view that is selected.
7. Subsequent measurements can be started from the Results screen by pulling and holding the trigger.

6.1.1 Troubleshooting

There are certain parameters that must be correct in order for the analyzer to take a measurement. The instrument must be set to search a library containing fingerprints, and the match number must be valid. The Analysis Screen displays the match number cutoff and selected libraries. This information is shown in green lettering, at the bottom of the screen.

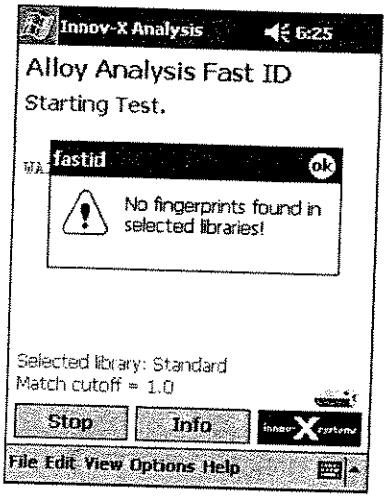
The selected library(ies) are listed. This is designed to allow the user to quickly verify that the correct library is being searched. The display will show "All" if all libraries are selected, or the names of the selected libraries. To change to Selected Libraries, choose ***File→Load Libraries***. It is recommended that all libraries are selected, unless it is necessary to search only a subset of stored fingerprints or grades.



The Match number is displayed to provide a quick check that the match number is set correctly. The factory set value for match numbers in FastID is 1. To change the match number, select ***Options→Fingerprint Settings***. More information about Match numbers can be found in the Advanced Features at the end of this section.

No Fingerprints Selected

It is impossible to start a test if no fingerprints are selected. If this is attempted, the following error message will result. Tap **ok** to acknowledge and clear the message box and select ***File→Load Libraries*** to choose libraries containing a valid number of fingerprints. See **Section 9.1.2: Loading Libraries** for more information.



Match cutoff too low

If the match cutoff is set too low, the instrument may fail to match alloys. Typically, the FastID match cutoff is set to 1. See the advanced features section at the end of this section for more information.

6.2 RESULTS DISPLAY

There are 3 possible ways to view information in the results screen; a user can view the Grade ID, the Grade ID and Chemistry, or the Raw Spectral Data. In addition, any test information entered for a reading may be viewed.

Regardless of what information is viewed, all results screens have similar characteristics. The **Date** and **Reading number** are shown at the top. Reading Numbers are useful for identifying readings. The first reading of a day will always be reading #1, thereafter; all readings within that day are labeled sequentially. Below the Date and Reading Number, the **Mode** used to acquire that reading will be listed.

Three buttons appear at the bottom of the screen: **Back, Next** and **Start**. **Back** and **Next** are used to scroll through stored data. The Start and Stop buttons are not active in most cases, and are normally only used in conjunction with a testing stand.

The results screens will show one of three possible results:

Successful Match
If an unknown alloy is a match to one of the grades contained in the Fingerprint libraries, a Grade ID will be shown.

Multiple Matches
In some cases, more than one grade will be shown as possible matches. This indicates that there was not enough statistical information to definitively separate two or more alloys, or the alloys are simply too similar to separate with portable XRF. The actual identification of the unknown alloy may be any one of the two grades listed.

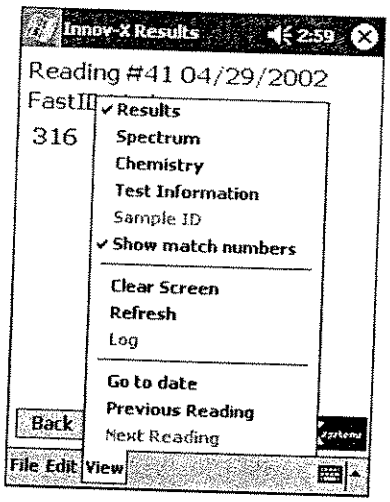
There are two procedures that may make it possible to separate the alloys:

1. Use a longer testing time. This will improve the measurement precision and may allow the alloys to be separated.
2. Define a specific element or elements that are different in the two alloys, which the analyzer can use to refine the identification. Please see Advanced Features later in this section for instructions to do this.

No Match
If no matches are found to the library, the words "no match" will be shown on the screen. If this occurs there may be several causes:

a. The alloy is not contained in the fingerprint library. Try using Analytical Mode to test the sample. Analytical Mode can provide chemistry information without requiring a library match. Alternatively, it is possible to add a standard to a library. This is described in Chapter 5.
b. The alloy may be coated. Try grinding or filing or sanding away any coating and repeat the test.
c. The testing time was too short. Trying increasing the testing time and measuring the sample again.
d. The match number is too low. See "Setting the Match cutoff" in the Advanced Features section of this chapter.

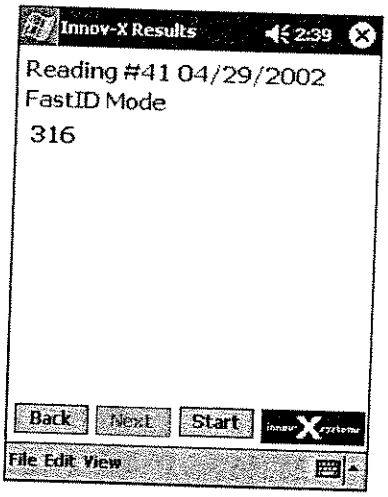
To change the appearance of the Results Screen click *View*, and select one of four choices: **Results**, **Chemistry**, **Spectrum** or **Test Information**. The active view will be denoted with a check mark.



6.2.1 Results Screen

This is the simplest screen. It displays only the Grade ID, and no extraneous information. This view is recommended if the primary goal of the analysis is grade identification, and it is not necessary to examine the chemistry results for every test.

Typically, one or more Grade IDs will be shown, or the words "No Match." In some cases, a number may be displayed after the grade identification. This is known as the match number. This number can be eliminated by Selecting ***View→Show Match Numbers***. This selection acts as a toggle. If ***View→Show Match Numbers*** is checked, match numbers will be displayed. Match numbers are described in greater detail in the Advanced Features part of this Chapter.

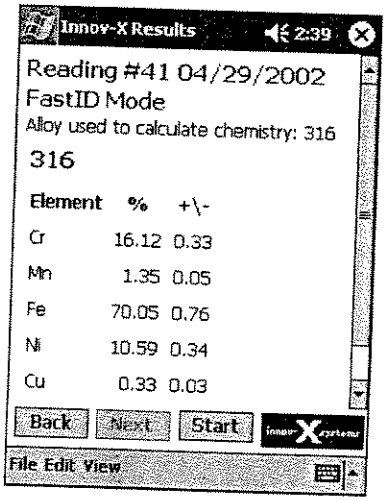


6.2.2 Chemistry Screen

This screen is the most versatile as it displays the Chemistry values, the uncertainty in the measurement and the Grade Identification. The Grade is listed at the top of the screen. The concentration (as a %) for all detected elements is then listed. After each concentration, the uncertainty in the measurement is shown. This is calculated as the 1-sigma error on the counting statistics.

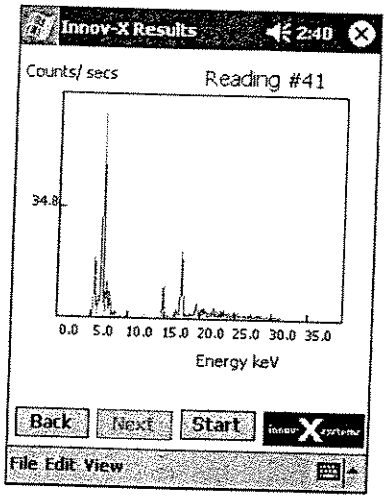
In cases where two or more matches shown, the results are based only on the first match listed. As a result there is some uncertainty associated with the chemistry values; however, given that two alloys are too close to separate, the chemistries should be fairly accurate.

Since **FastID** mode calculates chemistry results from standard assays, it cannot calculate chemistries for alloys that do not have assays stored in the fingerprint library. If no chemistries values have been entered in the library for any particular match, the message "Chemistry Values not calculated" will appear on the screen.



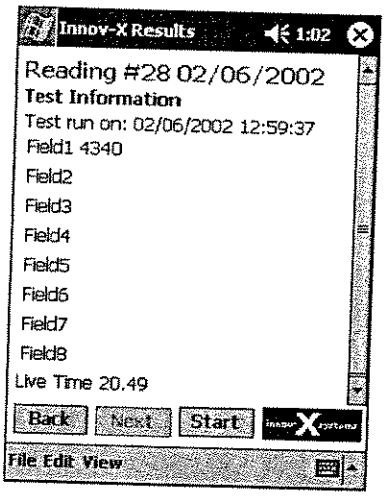
6.2.3 Spectrum Screen

This screen displays a plot of the x-ray fluorescence spectrum for an individual test, plotting the number of counts on the y axis versus the energy of the fluorescence x-rays on the x-axis. This spectrum is a unique energy signature resulting from the unique chemistry of the sample being tested.



6.2.4 Test Info Screen

The test information screen shows any information that was entered before starting a test.



6.3 ADVANCED FEATURES

This section we reviews two advanced features:

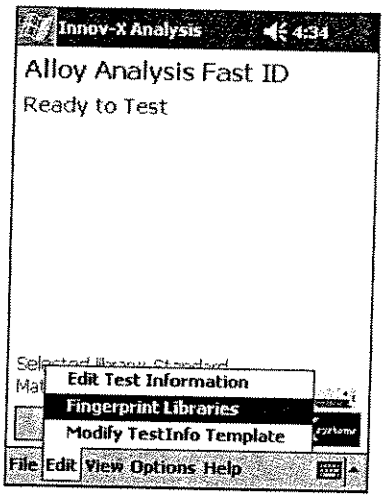
- Using Specific Regions to Separate Similar Alloys:
- Modifying the Fingerprint Cutoff Value

6.3.1 Specific Regions

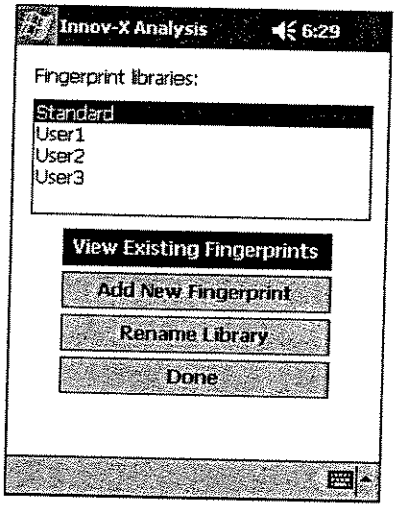
Some alloys only differ by a small concentration of a single element. For these alloys it may be necessary for the analyzer to examine the specific element or elements when performing a spectral match. In most cases, alloys that are difficult to separate when looking at all the elements may be easily separable if the analyzer is told to focus on one or more specific regions.

In order to instruct the analyzer to use one or more specific elemental regions, perform the following steps. This procedure can also be performed when reference standards are added by the user. For these instructions please refer the section on Adding a Fingerprint in Chapter 9. It is important to define the same specific elemental regions for all close alloys.

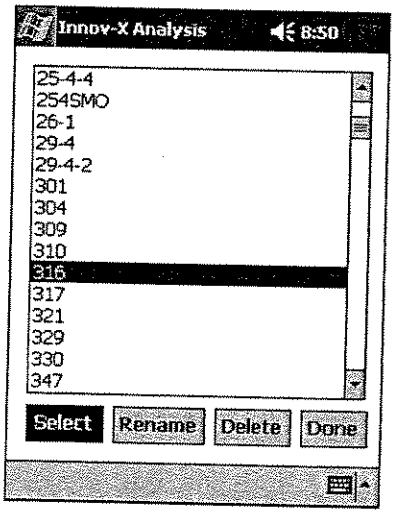
1. From the Analytical Menu, Select ***Edit→Fingerprint Libraries*** from FastID.



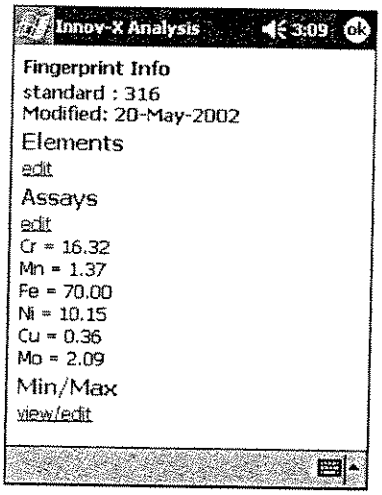
2. Select the library containing the alloy and click **View Existing Fingerprints.**



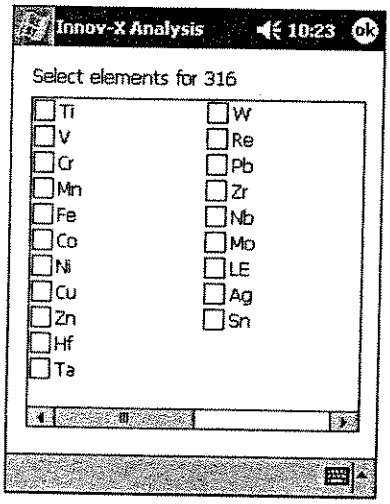
3. A list of the entries contain in the selected library will appear. Select the desired fingerprint.



4. Click the **edit** option underneath the heading **Elements**.



5. Tap the box for the element or elements you want to use for specific regions. A check will appear in that box. To disable this element, tap the element box again. The check will be removed. Select **ok**.



6.3.2 Modifying the Fingerprint Cutoff

In FastID Mode, the alloy matching is performed by comparing the x-ray spectrum of the sample to a library of reference spectra. Provided the sample spectrum is a close enough match to one or more reference spectra, the alloy grade(s) of the reference spectra is (are) displayed as the match. To determine a good match, a fingerprint match number is calculated by the analyzer by comparing the sample spectrum to the reference spectra. If the match number is below a pre-set cutoff value, then the sample is displayed as a good match to that particular reference standard. Ranges of match numbers are:

< 0.2 Excellent match
0.2-0.5 Good match
0.5-1.0 Reasonable match
1.0-2 Poor match
> 2.0 Sample is very different from reference standard.

Note: Factory default value = 1

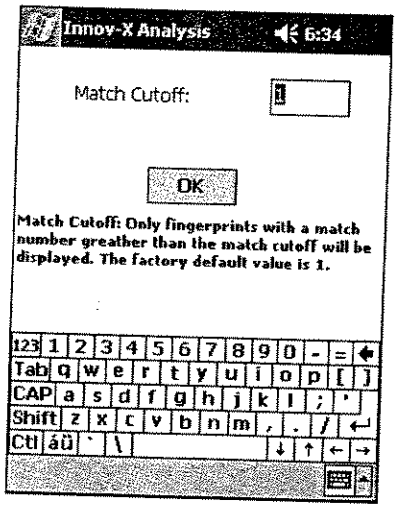
Generally, alloys within the same grade produce either excellent or good matches. Variations in match number occur because the reference standard has a slightly different chemistry than the sample being tested, even if they are the same grade. This is due to the usual grade-to-grade variations in the alloy chemistry. Testing small parts or parts with some surface oxidation may also elevate the match number.

Reasons to change the Fingerprint Cutoff:

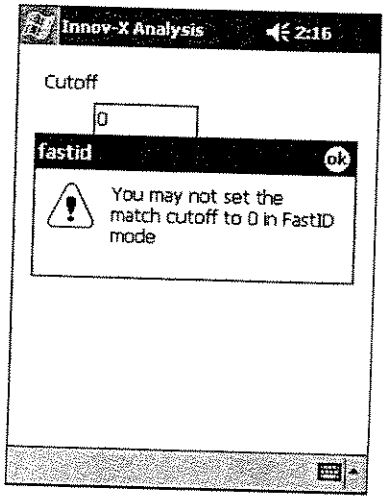
1. For sorting easily separated alloys such as 304 and 316, or alloys from different alloy bases, it is generally ok to raise the cutoff. This may be desirable if there is surface contamination like dirt, oil or mild oxidation, very small components like weld wire or turnings, or other things that may elevate the match number. It is advisable only to do this if the alloy sort being performed is known to be very easy for XRF technology.
2. The match cutoff may have been set to an extremely low number for a specific separation. If the match cutoff is too low, only very close matches will pass. Otherwise the result NO MATCH will be displayed.

How to Modify the Fingerprint Cutoff Value:

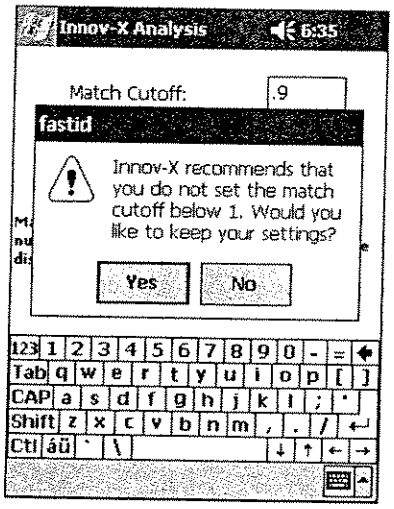
To change the Match number cutoff, from the Analysis Screen, select ***Options→Fingerprint Settings.*** The screen shown at the right will appear. Highlight the number shown in the box, tap the keyboard icon to bring up a keyboard, and enter a new cutoff value. Then tap OK.



If zero is entered for a match number, an error message will appear. Select ok to clear the message box, and select a valid match number. It will not be possible to close the Set Testing Times window with zero selected as a match number.



If the Match number is set to be a value below 1, a warning message will appear. Selecting **Yes** will keep the setting. Selecting **No** will allow the user to choose a new match number. Remember, the factory recommended setting for Match Number in FastID mode is 1.



7.0A Alloy Analysis—Pass/Fail

7.0 INTRODUCTION TO PASS/FAIL MODE

Pass/Fail mode is designed for high-throughput alloy sorting and quality control. All sorting is done by comparison to a reference standard which is chosen by the operator.

Analyzed samples are compared to the reference samples, and results are displayed as a PASS or a FAIL, depending on whether they match the reference standard. Pass/Fail criteria may be based on the quality of fit to the spectral fingerprint or on elemental chemistry. Pass/Fail ranges may be implemented for one or more elements. This mode offers a full range of options from the simplest sorting of mixed loads in a recycling facility to QC on specific element(s) in even the most complex superalloys.

Two options exist for Pass/Fail mode: **Fingerprint** and **Chemistry**. Fingerprint matching should be used when the goal of the analysis is to determine whether or not analyzed samples are a specific grade. Chemistry should be used when it is important to determine whether the chemistries for specific elements fall within specified min/max grade specifications.

Fingerprint Pass/Fail uses the same method used in FastID to determine matches. Data from analyzed samples are compared to the fingerprint of a reference standard. If the differences between the fingerprints are small enough, the sample is judged to be of the same grade as the reference sample. This method requires only that a valid fingerprint for the reference standard is contained in the library.

Chemistry Pass/Fail. In addition to requiring that an alloy matches the fingerprint of a specific alloy, it requires that all detected elements fall within specified ranges.

The process followed in chemistry Pass/Fail is as follows:

1. Analyzer uses the fingerprint method to determine whether the sample matches the reference sample. If it does not, it automatically fails.
2. In the case of a match in step one, the chemistry of the alloy is calculated from assays stored for the standard fingerprint.
3. The calculated chemistry for each element is compared to the values stored in a Grade Table. In order for a sample to pass, all the chemistries must be within n standard deviations of the min and max values specified in the grade table, where n is a number which can be specified by the user.

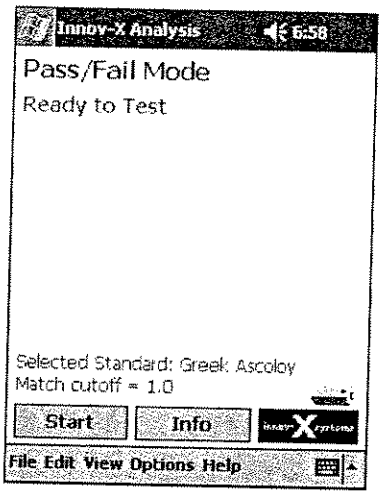
This method requires that a valid fingerprint, assays for that fingerprint, and Min/Max values are saved in the library.

7.1 USING PASS/FAIL

Before starting Pass/Fail mode, make sure that a signature for the reference sample you will be using is stored in the Fingerprint Library. You may use a fingerprint stored in the standard library, or you may add your own standard. To add a standard to the fingerprint library, follow the procedure listed in Chapter 9.

To start Pass/Fail mode, select Pass/Fail from the Main Menu. As with all modes, you will be informed if you must standardize the instrument before you can proceed with a measurement. Refer to the Chapter 4 for information on starting the analyzer and taking a measurement.

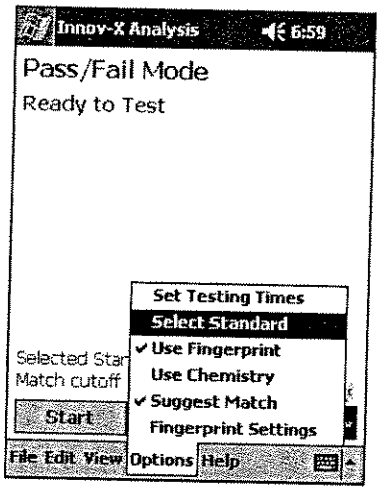
The Pass/Fail screen always shows the Selected Standard. This is the reference sample to which all other samples will be compared. Upon opening the mode, verify that the correct standard is selected.



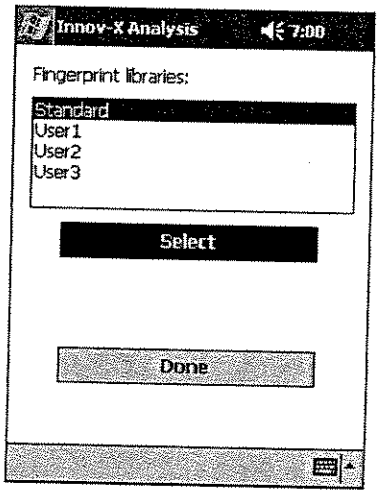
7.1.1. Selecting a Reference Standard

Once the standard you want to use is stored in a fingerprint library, select ***Options→Select Standard.***

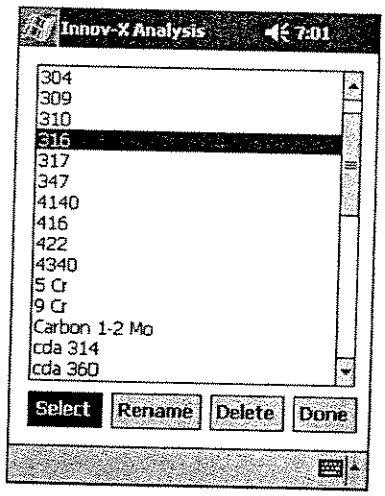
Enter your administrative level password when prompted.



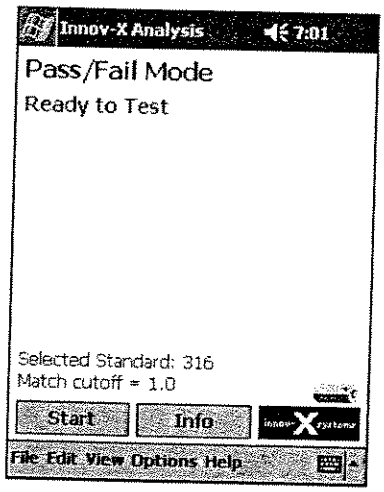
Select the library in which the fingerprint of your standard sample is stored. Choose the library and click **Select**.



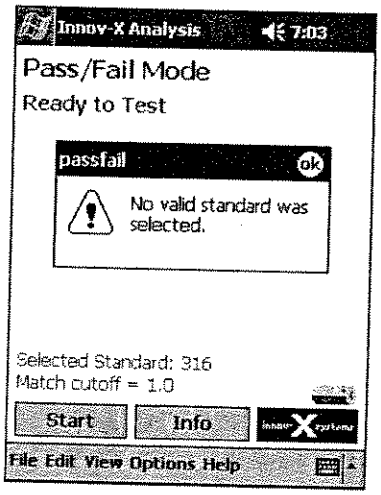
Select the name of your reference standard and click **Select**.



Verify that the proper standard is on displayed on the screen.



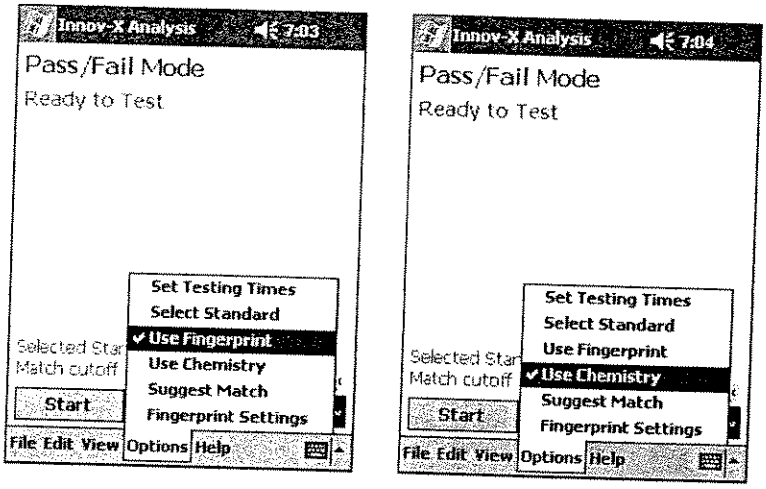
If you fail to select a standard, the instrument will always default to the last standard used. If a valid standard has not been selected, a warning message will appear. It will be impossible to start a test until a standard has been selected.



7.1.2. Select Pass/Fail Method

To use the fingerprint method and simply compare unknowns to a stored fingerprint, select ***Options → Use Fingerprint***.

Select **Options** → ***Use Chemistry*** from the menu if your Pass/Fail criteria will be chemistry-based.



7.2 ANALYZING A SAMPLE

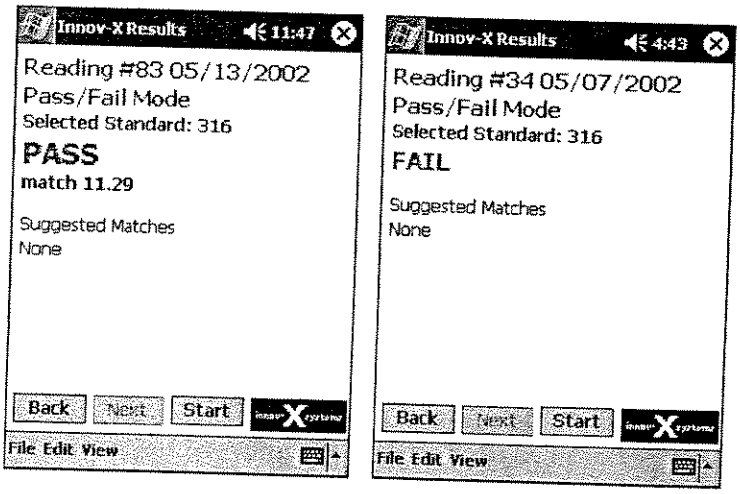
Once the instrument is successfully standardized as is described in section 4.4, your analyzer is ready for routine measurement.

1. Hold the analyzer up to the sample to be tested. Make sure the part of the sample you wish to analyze is in contact with the window on the front of the probe.
2. Unlock the trigger by tapping on the icon located on the iPAQ Screen directly above the battery indicator. Select Yes when prompted.
3. Pull the trigger to start the measurement. It is necessary to hold the trigger for the duration of the measurement.
4. While the analysis is in progress, the red LED on top of the instrument will blink, the amber light on the back of the instrument will turn on, and the screen will say "Test in Progress." In addition a "testing" icon will appear in the lower right hand corner of the iPAQ screen. All these indicators show that the X-ray tube is energized, and the shutter is open. During the testing time, it is important to keep the analyzer in contact with the sample surface, and to keep all body parts away from the measuring window.
5. A test can be aborted at any time by pulling the trigger, or by tapping **Stop** on the iPAQ screen.
6. Once the measurement is complete, the results screen will automatically open. The results will be displayed in one of two formats, depending on the view that is selected.

7.2.1 Use Fingerprint

Since Pass/Fail by fingerprint requires only that a valid fingerprint is selected, the analysis is very straightforward. Taking a measurement will open the results screen which will display the results of the measurement.

The results for Pass/Fail using Fingerprint comparison is very simple. Choosing ***View→Results*** will show only the reading, number, date, mode, selected standard and the result of the test; either the word **PASS** or **FAIL**. In the event of a failure, if the Advanced Feature: **Suggest Match** is

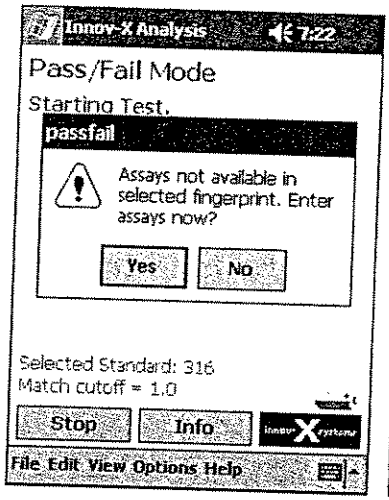


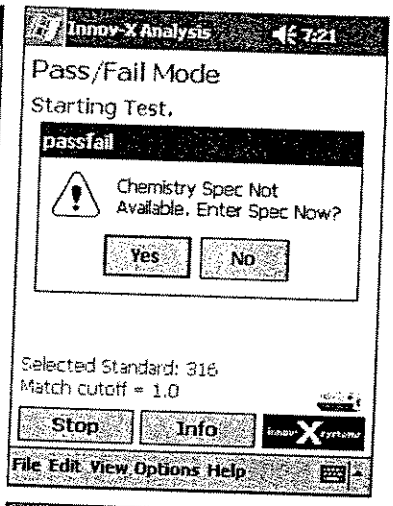
enabled; possible Grade IDs will be displayed on the screen.

7.2.2. Use Chemistry

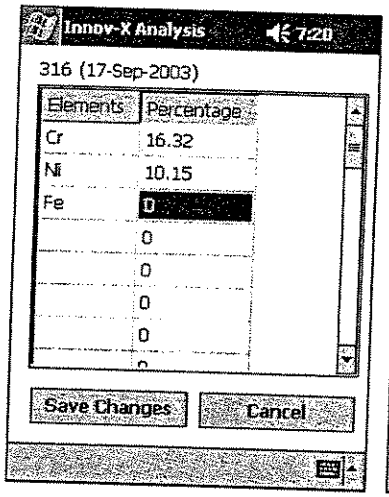
In order to get a valid reading with Use Chemistry selected, a fingerprint with an assay, and a grade table must exist. Since multiple parameters are required, it is strongly suggested that a known alloy grade is tested to make sure all parameters are set up correctly.

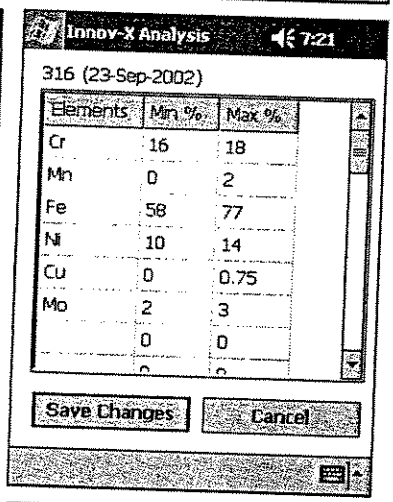
If a parameter is missing for a selected standard, a warning message will appear when the test is started indicating what needs to be added:



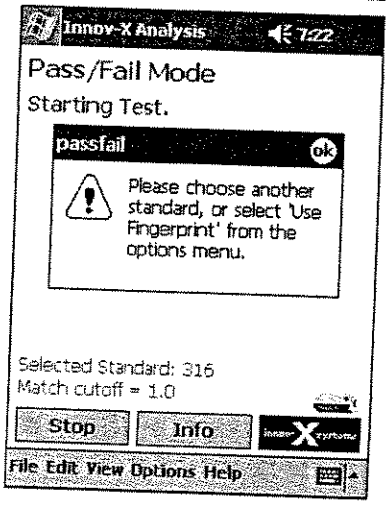


Selecting **Yes** to either of these screens will bring up either the Assays, or the Grade tables screen. Enter standard values in the assay table, and allowable Min/Max specifications in the Grade Table screen. Further information on either of these screens can be found in Chapter 9.





If you do not want to enter assays or grade libraries select No in response to the error message. You will not be able to take a reading until you either choose another standard or select Use Fingerprint.



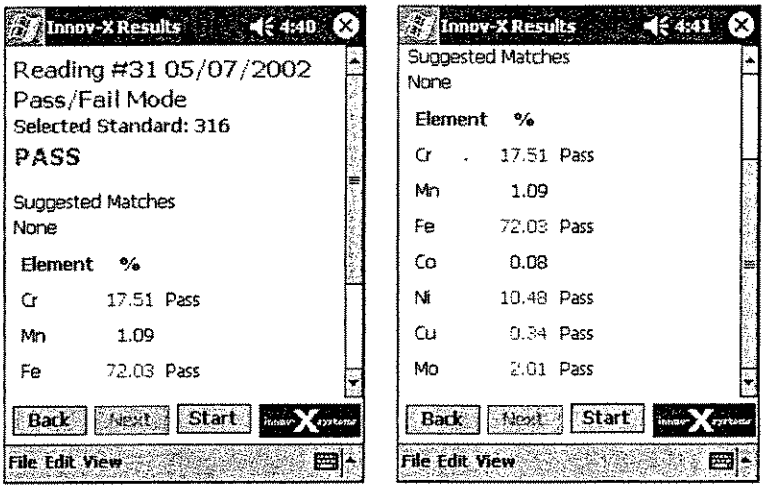
It is important that an assay is entered for every element that is listed in the grade table. If an assay is not listed for an element, the chemistry will not be calculated for that element. If this is the case, there will be

no value to compare to the Min/Max spec. This will result in an automatic failure for every sample. Make sure that a standard sample is measured to ensure it is possible to get a PASS result.

Results—Use Chemistry

In addition to the PASS or FAIL results, the Chemistry results screen will show the calculated chemistry results. The percentage reading for each element will be color coded to show whether the value is within spec. A green color indicates that the reading is within specifications; a red color indicates the element is out of spec. If no Min/Max specification is provided for an element, the concentration will be shown in black. Any elements that don't have Min/Max specs will not be used as criteria for determining Pass or Fail.

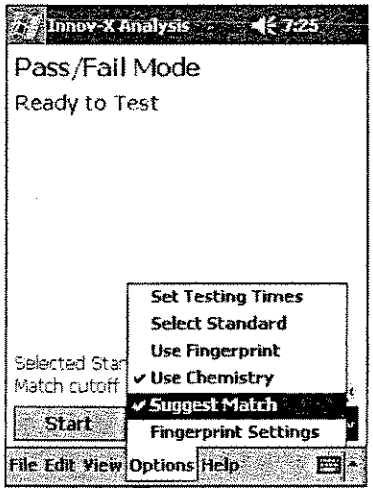
If the list of elements exceeds the room available on the screen, it will be necessary to scroll down to see the complete list.



7.3 ADVANCED FEATURES

Suggest Match: Suggest Match is designed to provide information about a sample in the event of a **FAIL** result. When suggest match is enabled, the software will search the library and provide a list of one or more possible Grade IDs if the sample fails to match the selected standard.

To activate Suggest Match, Select ***Options→Suggest Match***. Once suggest match has been selected, it will remain active until it is deselected. A checkmark before the menu selection will indicate that the option is enabled.



If suggest match is enabled, the analyzer will search all active libraries for the sample(s) with the lowest match number. The match number is an indication of the degree to which the analyzed sample matches a library entry. The number is unit-less, and will vary depending on a variety of parameters. In general, the closer a match number is to zero, the better the match.

Suggested results will appear only in the results screen, not in the chemistry screen. The display will indicate a no-match, or display the suggested match. In many cases, a single match will appear. However, in cases where it is impossible to statistically separate two or more matches; all close matches will be displayed on the screen. Keep in mind that a suggested match is not necessarily a correct grade identification. It is simply the closest matching grade found in the fingerprint library.

8.0A Alloy Analysis—Analytical Mode

8.0 INTRODUCTION TO ANALYTICAL MODE

Analytical mode utilizes a Fundamental Parameters (FP) algorithm to determine elemental chemistry. This method calculates chemistry from the spectral data, without the requirement of stored fingerprints. The Analytical FP calibration is done at the factory, and requires no user set-up or recalibration. The software also searches an alloy grade library to produce a grade match to calculated chemistry, based on the calculated chemistry. Analytical mode can provide a grade ID and chemistry in as little as 2-3 seconds, with increased precision for longer test times.

The FP method utilized in Analytical mode is ideal for applications that require analysis of proprietary or uncommon alloys, for monitoring chemistry of tramp elements, or for monitoring chemistry during processing. The fundamental parameters method is also ideal for obtaining an average chemistry of turnings, especially mixed turnings.

In many ways, analytical mode is the easiest to use of all the modes, since it is possible to acquire good solid chemistry data and grade identifications by using only the instrument default setup. Users who are analyzing complete unknowns or samples from a wide variety of alloy families may find this to be the most appropriate mode for their needs.

Determination of Grade Identification:

Analytical mode utilizes a Grade Library consisting of a set of minimum and maximum values for each element in an alloy. The factory installed standard grade library contains 250 alloy grades. The Operator may add up to 300 additional alloys. These alloys may be added to any of the 3 user libraries or to the standard Grade Library. For the sake of simplicity, we recommend any alloys added be added to the user libraries and not the Standard (Factory) library. The libraries may be searched individually or together. All libraries, including the standard library, may be edited by the user.

Analytical mode calculates chemical composition using a fundamental parameters algorithm. Once these values are calculated, they are compared to the grade tables stored in the grade library. The software calculates a number, called a Match Number, which is an indication of how close the chemistry of a measured alloy is to the library values. The lower this number, the better the match. A match number of 0 is an exact match, meaning that the calculated chemistry for all elements falls within the grade table specifications.

The presence of tramp elements, as well as uncertainty associated with any measurement, makes it possible for a valid match to fail to register as an Exact Match. Therefore, a cutoff value is set to determine whether or not a grade is considered a match. If the Match Number is below the cutoff value, it is considered to be a good match. The default cutoff value is set at a value that works for a wide range of alloys, but it may need to be adjusted for certain specialty applications.

8.1 USING ANALYTICAL MODE

A detailed startup procedure is described in chapter 4. The procedure is summarized here:

1. From the main menu, select Analytical Mode by tapping on the word "Analytical".
2. Hold the analyzer up to the sample to be tested. Ensure that the sample is as flat as possible against the window, and is covering as much of the window as possible.
3. Unlock the trigger by tapping on the icon located on the iPAQ Screen directly above the battery indicator. Select Yes when prompted.

4. Start the measurement by pulling the trigger. When a test is in progress, the words "Test in Progress" will be displayed, along with the elapsed time of the measurement and a "testing" icon. The LED on the front of the instrument will blink, indicating that the X-ray tube is on, and the shutter is open.
5. Make sure the sample maintains contact with the analysis window for the entire duration of the test.
6. When the test is complete, the words "Test Complete" will appear. For the first reading of the day, there will be a slight delay while the results screen is opened. This will be indicated by the appearance of a rotating icon in the center of the screen.
7. After taking the initial measurement, tests can be started from the results screen by pulling the trigger. This will close the results screen and display the analysis screen, which will show the progress of the test.

8.2 RESULTS DISPLAY

There are 3 possible ways to view information in the results screen; a user can view the Grade ID, the Grade ID and Chemistry, or the Raw Spectral Data. In addition, any test information entered for a reading may be viewed.

Regardless of what information is viewed, all results screens have similar characteristics. The **Date** and **Reading number** are shown at the top. Reading Numbers are useful for identifying readings. The first reading of a day will always be reading #1, thereafter; all readings within that day are labeled sequentially. Below the Date and Reading Number, the Mode used to acquire that reading will be listed.

Three buttons appear at the bottom of the screen: **Back, Next** and **Start**. **Back** and **Next** are used to scroll through stored data. The **Start** button is inactive in most cases, but may be used in conjunction with the test stand.

The results screens will show one of three possible results:

Successful Match
If an unknown alloy is a match to one of the grades contained in the Fingerprint libraries, a grade ID will be shown.

Multiple Matches
In some cases, more than one grade will be shown as possible matches. This indicates that there was not enough statistical information to definitively separate two or more alloys. The actual identification of the unknown alloy may be any one of the grades listed. Increasing the testing time may make it possible to separate the alloys.

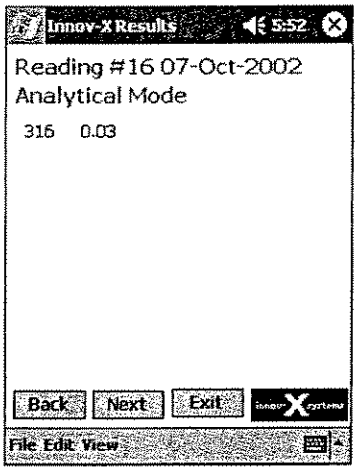
No Match
If no matches are found to the library, the words "no match" will be shown on the screen. If this occurs there may be several causes:

a. The alloy does not meet any of the specifications in the Grade Library.
b. The alloy may be coated. Try grinding or filing or sanding away the coating and repeat the test.
c. The testing time was too short. Trying increasing the testing time and measuring the sample again.
d. The match number is too low. See **Section 8.3.1: Nearest Match/Exact Match** for more information.

To change the appearance of the Results Screen click ***View***, and select one of four choices: **Results, Chemistry, Spectrum or Test Information**. The active view will be denoted with a check mark.

8.2.1 Results Screen

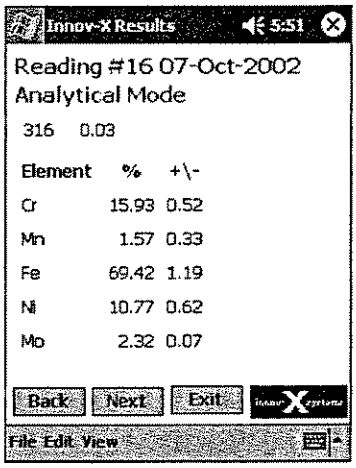
This is the simplest screen. It displays only the Grade ID, and no extraneous information. This view is recommended if the primary goal of the analysis is grade identification, and it is not necessary to examine the chemistry results for every test.



Typically, one or more Grade IDs will be shown, or the words "No Match." In some cases, a number may be displayed after the grade identification. This is known as the match number. This number can be eliminated by Selecting ***View→Show Match Numbers***. This selection acts as a toggle. If ***View→Show Match Numbers*** is checked, match numbers will be displayed. Match numbers are described in greater detail in the Advanced Features part of this Chapter.

8.2.2 Chemistry Screen

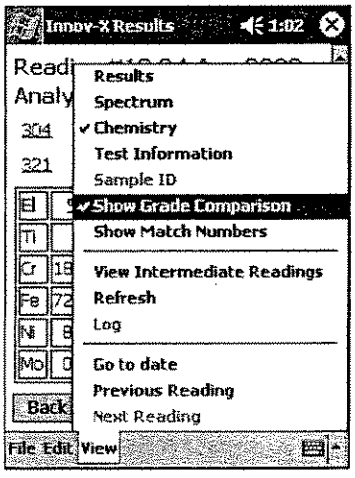
This screen is the most versatile as it displays the Chemistry values, the uncertainty in the measurement and the Grade Identification.



The Grade is listed at the top of the screen. The concentration in percent for all detected elements is then listed. After each element's chemistry, the uncertainty in the measurement is shown. This is calculated as the 1-sigma error on the counting statistics.

8.2.2A Grade Comparison

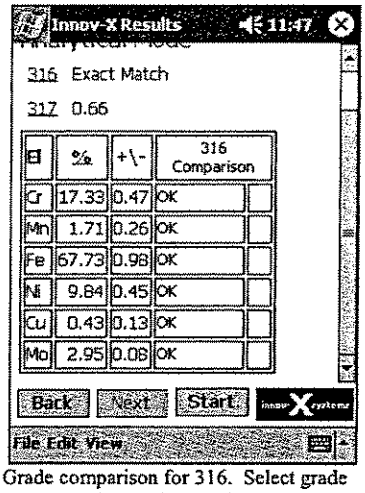
The Show Grade Comparison feature allows users to see at a glance which elements are outside the concentration range specified for a Grade Match. When this feature is activated the results will show up in a table format. If the chemistry of an element, plus or minus the error on the reading, is within the specified range for a specific grade, the word "OK" will appear next to that element. If the chemistry is out of range, the screen will indicate whether the measured elemental value is "low" or "high" and list the corresponding grade specification.



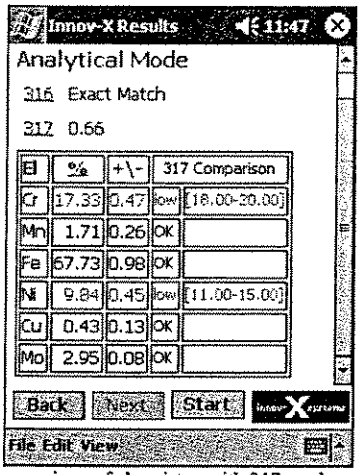
The show Grade Comparison function works only in the Chemistry view. If the results screen is not displaying chemistry results, select **View→Chemistry** from the results screen. Show Grade Comparison can be turned on or off by selecting **View→Show Grade Comparison** from the Results screen. A check mark will appear on the menu if the feature is active.

When Show Grade Comparisons is active, it is possible to show the comparison for any Grade that appears as a match for the analyzed sample. Select which grade comparison to view by tapping on the name of that grade.

The figures show the results for the measurement of 316. Both 316 and 317 show up as matches, however, 316 shows up as an "exact match" while 317 has a higher match number. The grade comparison shows that all the elemental concentrations are within specification for 316, while the Cr and Ni are both lower than specified for 317. Obviously, 316 is a better match and is the correct grade identification for the alloy.



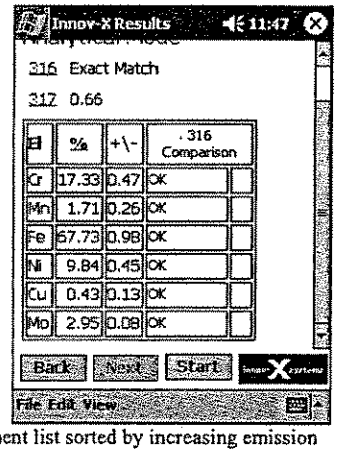
Grade comparison for 316. Select grade to compare by tapping on the name of the grade.



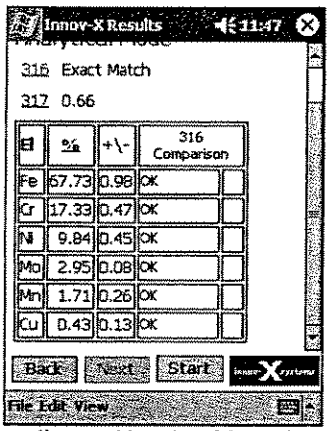
Comparison of chemistry with 317 grade spec.

8.2.2B Changing the order in which elements are displayed

Users may order detected elements in two ways; by emission line energy, or in order of decreasing concentration. To change the order, simply tap on the blue "%" header above the column displaying elemental chemistry. Tapping this header will switch the order. Tapping again will return the list to its original order.



Element list sorted by increasing emission line energy.

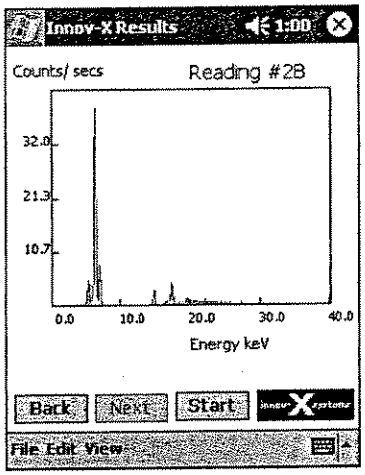


Element list sorted in order of decreasing composition.

8.2.3 Spectrum Screen

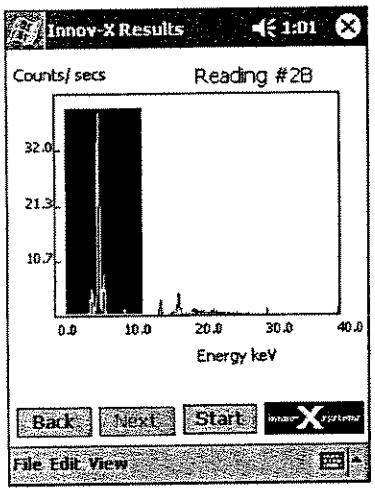
This screen displays a plot of the x-ray fluorescence spectrum for an individual test, plotting the intensity on the y-axis versus the energy of the fluorescence x-rays on the x-axis.

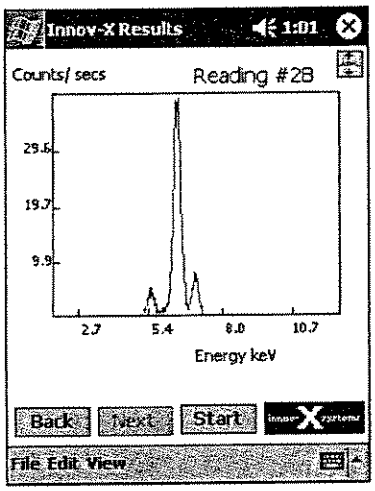
Tapping on the spectra will show the energy scale and count rate at the selected point.



It is possible to zoom in on certain areas of the graph by selecting one corner and drawing out the out the region

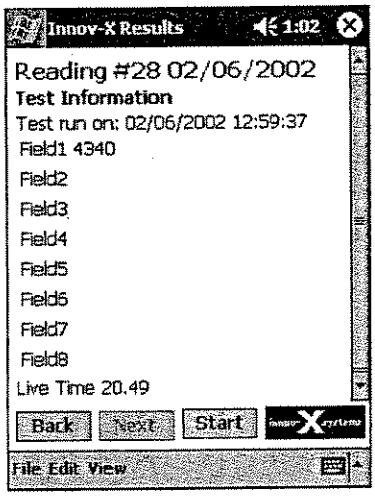
Tapping the symbol in the upper right hand corner beneath the X will restore the graph to full scale.





8.2.4 Test Info Screen

The test information screen shows any information that was entered in **Test Information** before the test was started.



8.3 ADVANCED FEATURES

8.3.1 Nearest Match/Exact Match

After calculating chemistry with the Fundamental Parameters algorithm, the analyzer software searches the Grade Library for alloy specifications which are close to the calculated chemistries. In order to evaluate which alloy is the best match for the measured sample, a number is calculated which compares the measured samples to the Grade Table. This number, referred to as a match number, is a measure of the difference between the measured chemistry and Minimum and Maximum specifications for the various alloys. A Match number of zero (0) indicates that measured chemistry is an "EXACT MATCH;" the measured chemistry for all detected elements falls within specifications. It is possible to have good matches that are not "EXACT," as there are uncertainties associated with any measurement. The presence of tramp elements (small amounts of unspecified elements) may also elevate the match number on valid matches.

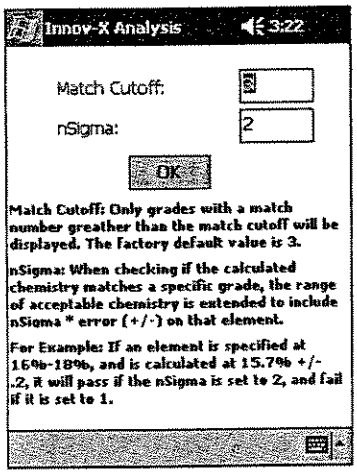
It is possible to specify whether the analyzer will report all possible matches, or just Exact Matches. These two options are referred to as Exact Match and Nearest Match. To switch between Exact and Nearest Match modes, select ***Options***. Clicking on ***Exact Match*** works as a toggle. If a checkmark appears before the words "Exact Match," Exact match is enabled. Otherwise, Nearest Match is the active method.

- **Nearest Match** When the analyzer is in Nearest Match mode, it calculates chemistries using the fundamental parameters algorithm, and searches the grade libraries and determines which alloy(s) is the closest match to the calculated results. The analyzer determines whether a grade is considered a match by comparing the calculated Match Number for that alloy to a cutoff value. This cutoff value is user modifiable. Typically this cutoff value is set at 3 and should not be changed, except in very special circumstances.

- **Exact Match** Exact match requires that all chemistry values are within a user settable error band of the min/max values specified in the Grade Libraries. The allowable error band can be changed by modifying the "nSigma" value. If nSigma is set as 0, all chemistry values must fall within the Grade Specifications. If nSigma is set as 2, for example, the chemistry value +/- 2*precision must fall within the Grade Specifications.

  Both the nSigma and Match Cutoff values are changed by selecting ***Options→Grade Library Settings.***

  A brief description of each field appears on this screen

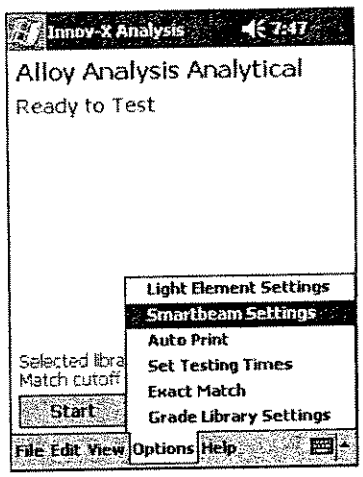


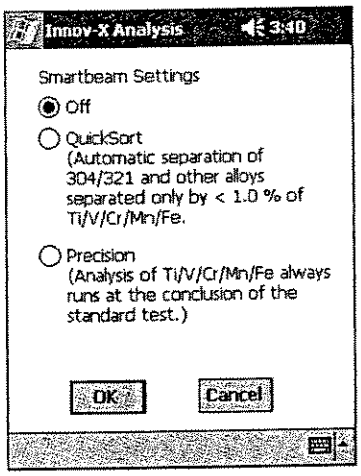
8.3.2 *Smartbeam* (optional feature)

Smartbeam adjusts the voltage, current and filtering to optimize detection of Ti and V in alloy samples. This feature is designed to provide quick, accurate separations of alloys which contain low concentrations (<1.0 %) of Ti and V, and to provide accurate and precise measurements of these elements.

Users can configure ***Smartbeam*** in two different ways: **Quicksort** mode provides automatic separation of alloys separated by a small amount of Ti or V. This mode *automatically* turns on ***Smartbeam*** and does a test with a second beam condition; if an alloy is found to match two alloy grades that only differ by a small amount of Ti or V. **Precision** mode forces ***Smartbeam*** on for every test in order to get precise chemistry on Ti and V at low levels. ***Smartbeam*** can also be disabled when it is not required.

Smartbeam settings:
To configure ***Smartbeam***, Select **Options→Smartbeam Settings** from the Analytical "Ready to Test" screen. A screen will appear providing three options.





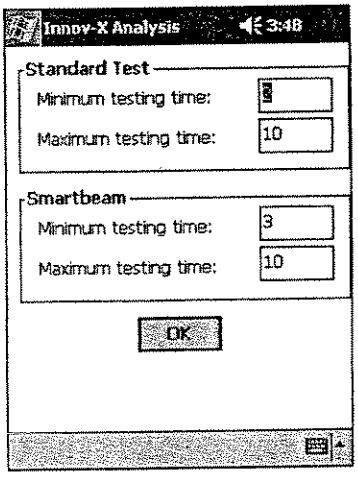
***Smartbeam* Off:**
If ***Smartbeam*** is disabled, the analyzer will perform a single, one beam analysis. This will separate most alloys; however a short test will not be sufficient to separate alloys which differ by a small amount of Ti or V. This is the recommended mode if the separation of alloys such as 304 and 321 is not required.

Quicksort:
Quicksort is the recommended ***Smartbeam*** setting for most applications. It allows for the quickest throughput of samples while maintaining the ability to separate alloys which require ***Smartbeam***. The analyzer automatically switches to a second beam condition when presented with a sample which closely matches two grades that differ by a small amount of Ti and/or V.

Precision:
This mode does a two beam test on all samples. Precision mode is only recommended for users who require precise chemistry on low concentrations of Ti and V. This is the most infrequently used ***Smartbeam*** option.

8.3.2A Setting *Smartbeam* Testing time

The Options **Set→Testing Times** screen for instruments equipped with ***Smartbeam*** allows users to set the smart beam testing times, as well as those for the Standard Test. Typical Testing times are shown.

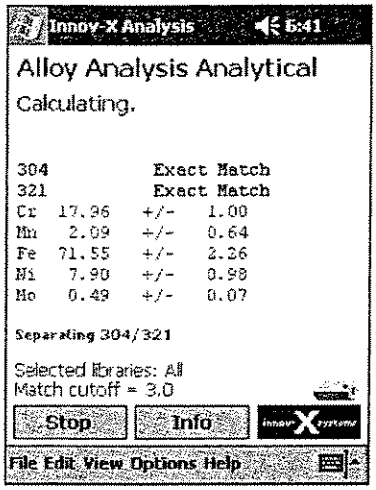


8.3.2B Testing with *Smartbeam* Enabled

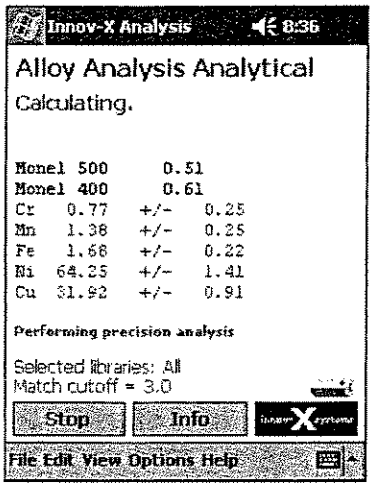
Once ***Smartbeam*** is enabled, users will operate the instrument exactly as they do when ***Smartbeam*** is disabled. Tests are started and stopped via the trigger. The analyzer will start by testing using standard beam conditions, then switch to the second beam condition automatically, if appropriate.

If Quicksort is active, the instrument will start a test using the standard beam settings. If a sample is found to match two alloys which differ by only a small amount of Ti or V, the instrument will switch to a 2nd beam condition. It will test using the second beam until the maximum testing time for beam 2 has elapsed. When the analyzer switches to 2nd beam conditions, it will display the name of the two alloys being separated.

If the alloy has a unique ID, or if the best matches differ by something other than a small amount of Ti or V, the analyzer will function as it does with Smartbeam deactivated.

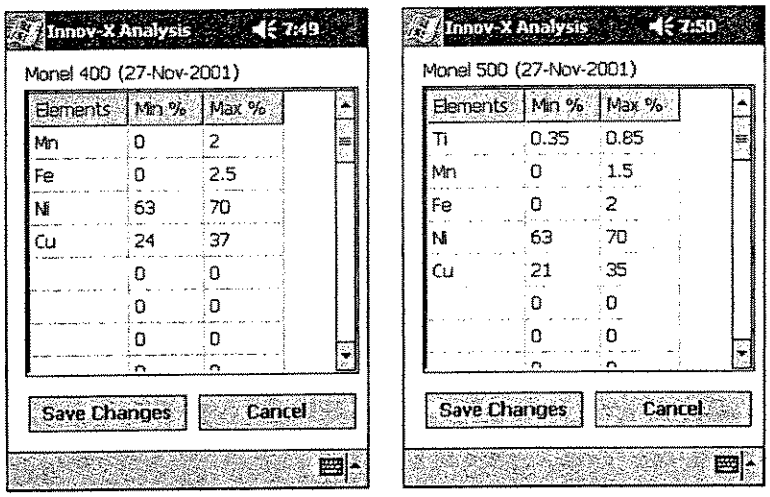


If Precision mode is active, the instrument will automatically switch to the second beam condition after the set time has elapsed for the standard beam. When the second beam is active the words "Performing precision analysis" will appear on the screen. The second beam will be active for the amount of time specified in the **Set Testing Times** screen, under the ***Smartbeam*** heading. At the completion of the test, a final result which reflects information from both beam settings will be displayed.



8.3.2C Creating alloy grades which utilize Quicksort *Smartbeam* Separation Mode.

When Quicksort is activated, the software uses the grade library to determine which alloys require a second beam analysis for separation. If the grade specifications for two alloys overlap completely, with the exception of Ti and/or V, Quicksort will use a second beam test. For example, the grade specifications for Monel 400 and 500 are shown below. They do not completely overlap, however, there are numerous concentrations which fall within the specifications of both grades. A second beam test will be required if a sample matches both of these alloys because Ti is specified in 500, but not 400.

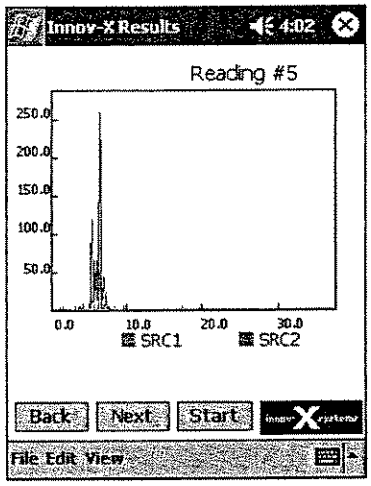


The most common grades requiring ***Smartbeam*** for quick separation; 304/321 and Monel 400/Monel 500 are included in the library. Users may add alloys to the library simply by entering the grade specifications. Quicksort will automatically use the second beam if a sample matches 2 alloys whose grade library specifications differ by <1% of Ti or V.

8.3.2D ***Smartbeam*** Results

The Chemistry results screen for ***Smartbeam*** tests is identical to that for standard tests. A single result is shown which includes information from both beams.

The Spectrum screen shows spectral overlays of data from both beams.



8.3.3 Light Element Analysis.

Innov-X Portable analyzers, like all hand-held XRF analyzers, cannot directly detect "light" elements such as Al, Si and Mg. In this manual, and in the software, light elements will be referred to as "LE" for light element. In practice Al is the most common light element of concern in alloys measured, so most of this discussion focuses on how aluminum is handled.

Innov-X analyzers handle light elements in two different ways.

1. **Use of nominal value**. All Analytical results are normalized to 100%. Since Al is invisible to the analyzer; the presence of several percent of Al can cause the other elements to appear too high after normalization. To correct for this, the software can normalize to 100% minus a nominal value for LE.

- Users should enter a nominal value for Al (or any other light element) as LE. If LE is specified for a grade, and the grade is found to be the best match for an alloy, the analyzer will use the average of the min and max specification as a nominal value. The measured results for all other elements will be normalized to 100% minus the LE nominal value.
- This is most useful for compounds which have less than 10% aluminum. This is typically used for titanium alloys and some copper alloys.

This method does not measure LE. It relies on data in the grade libraries. It's designed primarily to reduce the bias on other elements that can be caused by a significant amount of Al or other light elements. The nominal LE value will appear in blue to indicate that it is calculated, not measured.

2. **Calculation of LE using scatter lines.** A portion of x-rays from the x-ray tube are scattered back to the detector. The amount of scatter can provide additional information about the sample. In particular the amount of inelastic scatter, called Compton scatter is increased as the density decreased. As a result, the scatter lines can be used to indirectly calculate the LE concentration in low density samples, such as Aluminum alloys.
   - This method is recommended mainly for aluminum alloys, which typically contain more than 85% aluminum
   - The software will calculate the LE from the scatter lines, and all other elements from their x-ray emission lines. LE will be treated as any other element and included in the grade library search. Thus, Al alloys need to be included in the library for proper identifications.
   - Although this method can determine the amount of LE in an aluminum alloy, it is only sufficient to sort major grades of Al alloys. Many aluminum alloys cannot be separated because they differ by small amounts of Si, Mg or other light elements which cannot be measured. Please contact Innov-X System for more information on the capability of the analyzer for testing Al alloys.

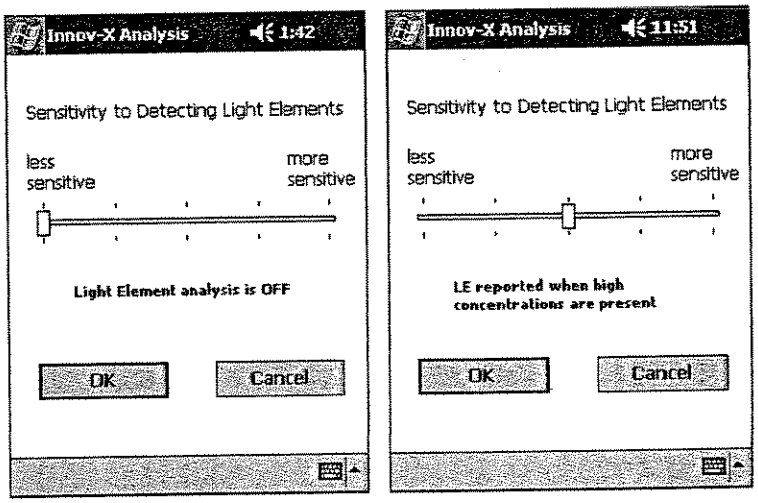
Since the calculation of LE is done indirectly, LE can be reported erroneously in some conditions if the amount of scatter is increased. For example, some customers who produce specialty alloys wrap the samples in plastic before testing. This scatter from the plastic will be erroneously reported as LE. Likewise, irregularly shaped or heterogeneous samples can, on occasion, produce false LE readings.

For these reasons, Innov-X allows customers to adjust their analyzer's sensitivity to Light Element detection. To change the LE sensitivity, select ***Options→Light Element Settings***.

If aluminum alloys are never measured, the slider bar should be positioned all the way to the left. This will ensure that Light elements are not erroneously detected. The default setting for all analyzers disables *Light Element analysis*.

Customers who measure Al alloys should set the slider to the middle of the screen.

The most sensitive setting should be used only in special cases, when recommended by Innov-X Application staff.



9.0A Alloy Analysis—Libraries

9.0 LIBRARIES

All reference data for alloy identification is stored in a standard database, or library. Libraries are all completely editable by a user with password privileges.

There are two types of library entries: Fingerprints and grade tables. Fingerprints are used in both FastID and Pass/Fail modes. Fingerprint files contain a variety of information about a standard sample, including a spectral fingerprint, assay information, and a link to a grade library entry. Grade tables contain minimum and maximum specifications for each element present in an alloy. Grade tables are used in Analytical mode, as well as in Pass/Fail if use chemistry is selected.

A library entry may contain a variety of information about the sample. This information includes:

1. Fingerprint files (editable through FastID or Pass/Fail Modes). These files may contain:
   - Spectral signatures. Signatures or fingerprints are the basis for identifying samples in both FastID and Pass/Fail Modes.
   - Specific Elements—This information is used by the FastID Specific regions Advanced feature. This is used to separate alloys that are very close and differ by only one or two elements. Certain elemental regions are selected for comparison.
   - Assays—These assays are used by FastID and Pass/Fail mode to calculate chemistry.
   - Min/Max Ranges. These are used in Pass/Fail mode for matching by chemistry. Creating Min/Max tables in Fingerprint mode results in a grade table that can be used and edited in analytical Mode.

2. Grade tables (editable through analytical mode)
   - Grade tables include a list of minimum and maximum specifications for use in grade matching.

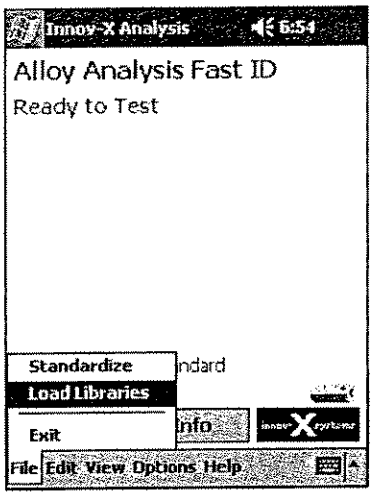
The spectral signature is automatically stored when the user adds a fingerprint to a library in FastID mode. The remaining information can be entered by the user if it is relevant. In order to calculate chemistry in either FastID or Pass/Fail, an assay must be entered. A grade table must exist to use Pass/Fail chemistry, or to get a grade ID in Analytical mode.

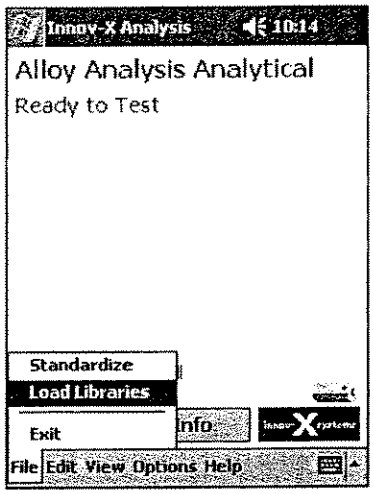
9.1 SELECTING A LIBRARY.

There are four libraries available. Each library can contain both Fingerprints and Grade Tables. The first library is the Standard Library which contains up to 300 fingerprints or grades and is supplied with every analyzer. Typically 35 FastID, and 200 Grade Tables are supplied with new analyzers. The remaining three libraries are empty, and are available for users to use create their own custom libraries. Each of these libraries can contain up to 100 samples, for a total of 300 custom samples. Users may add standards to any of the custom libraries, as well as to the standard library, however, it is good practice to make changes only to the user libraries.

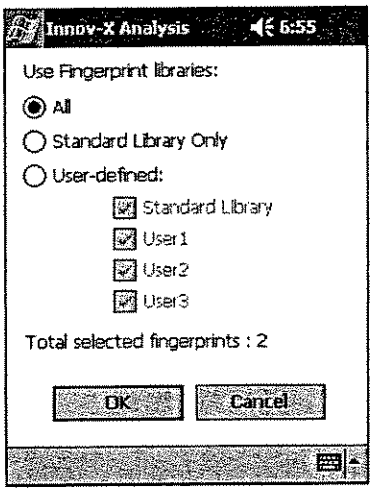
Each of the libraries may be searched individually, or in combination with any or all of the other libraries. The default setup searches all four libraries. It is possible to search any library in FastID. Pass/Fail will use only one fingerprint, so it is not necessary to select a library to search.

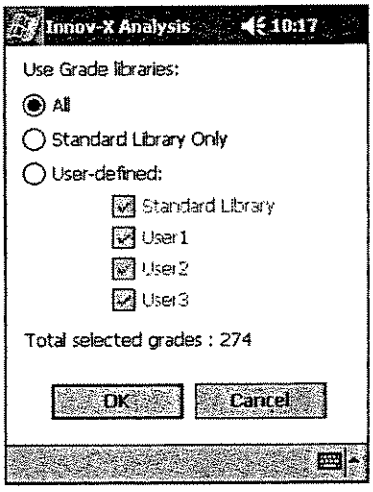
To select which library to search, select ***File→Load Libraries*** from either the FastID or the Analytical Analysis Screen.





A menu will appear. The first line reads **Use Grade Libraries** for Analytical Mode or will read **Use Fingerprints** for FastID Mode.





Choose the Fingerprint or Grade Libraries you wish to search. For the most general search, select **All** libraries. This will search the entire Standard Library, as well as any fingerprints that have been added by the user.

Users who are primarily concerned with sorting the most common specialty, stainless, nickel and high temperature alloys should always search the **Standard Library**.

Users who are sorting a small group of alloys may prefer to create their own libraries using their own standards. In this case, only the appropriate user library should be selected.

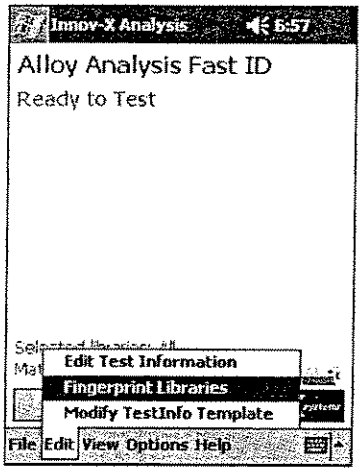
9.2 EDITING LIBRARY FUNCTIONS

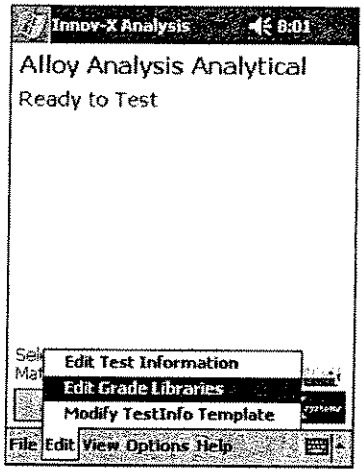
Innov-X Systems libraries are completely user editable. Library entries may be added, deleted, renamed, and the information contained within them, such as assays and min/max grade tables, can be modified.

The information contained in libraries is essential to the proper functioning of your analyzer. Care should be taken when editing libraries as incorrect settings may result in incorrect grade identification.

It is recommended that the standard library is not modified. All new alloys should be added to a user library.

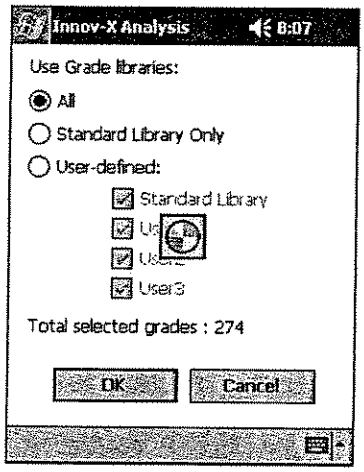
The edit libraries menu is reached by selecting either ***Edit→Grade Libraries*** from Analytical Mode, or by selecting ***Edit→Fingerprint Libraries*** from FastID or Pass/Fail modes.





All library functions require an administrative level password. The password needs to be entered only once during each editing session. The default administrator password is a lowercase z. This password can be changed from the main menu.

When you are finished with any edits, there may be a slight pause while the analyzer loads and re-indexes the library. This will be indicated by the following graphic, which will rotate in the center of the screen.

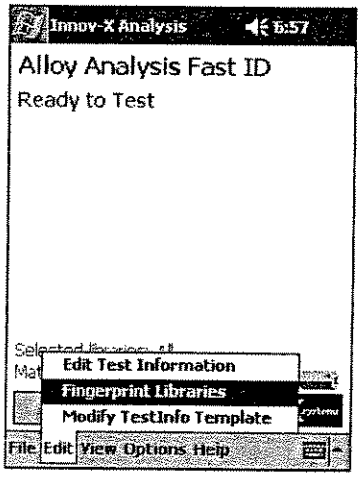


Functions such as renaming and deleting libraries are the same for both Fingerprint Libraries and Grade Libraries. They will therefore be described together in the following sections. Editing library contents and adding new library entries require different procedures for different library types and will be described separately at the end of the chapter.

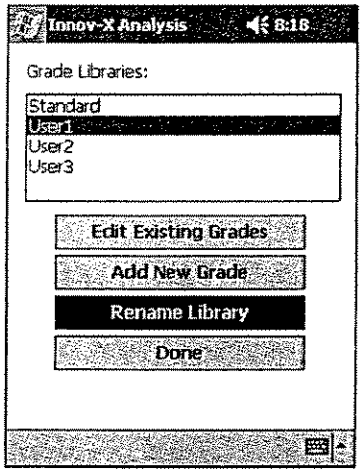
9.3 CHANGING LIBRARY NAMES

The default names for the libraries are Standard Library, User1, User2 and User3. It is possible to change the name of each of the User Libraries; however, the Standard Library can not be renamed. When a library is renamed, the new name will be used for all alloy modes, regardless of the mode that was active when the name was changed.

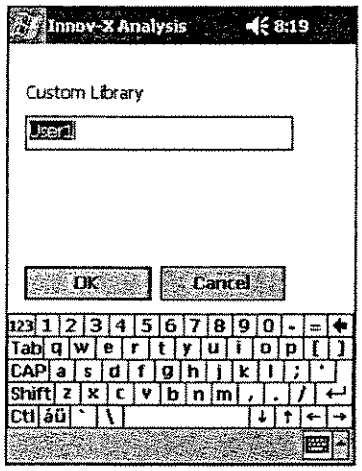
1. Library names can be changed either by selecting ***Edit→Grade libraries*** from Analytical Mode or by selecting ***Edit→Fingerprint libraries*** from Pass/Fail or FastID Mode.



2. To rename a library, select it and tap **Rename Library.**
3. Enter the administrative password when prompted.



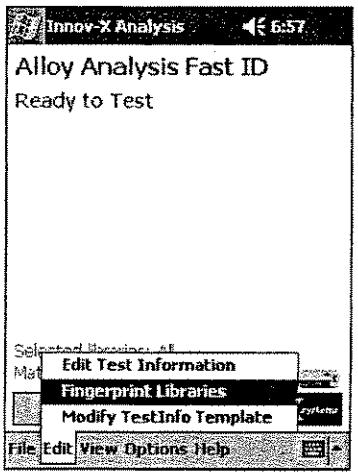
4. Type in the new name. The name may include any combination of letters or numbers, but may not include the characters "/", "." , "+", "_" or "?" . Enter the new name via the virtual keyboard. Tap **OK** to save the new name. If you do not wish to modify the name, select **Cancel.**



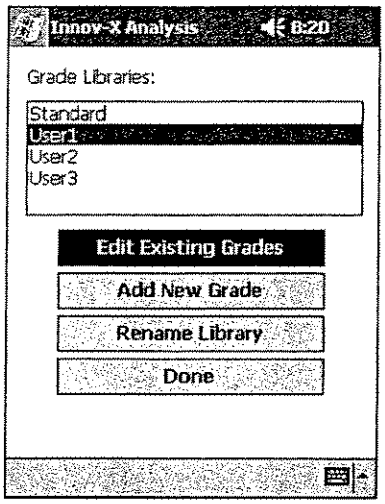
9.4 CHANGING THE NAMES OF INDIVIDUAL FINGERPRINTS OR GRADE ENTRIES.

If typographical errors are made when entering the name of a library entry, the name may be edited. Care should be taken when renaming a library entry. The name must correspond to the data saved in the file. An incorrect Fingerprint or Grade name will result in a wrong Grade ID

1. From the Analytical Menu, Select ***Edit→Grade Libraries,*** or select ***Edit→Fingerprint Libraries*** from FastID or Pass/Fail.

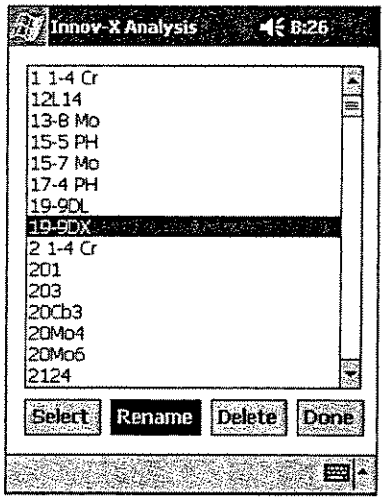


2. Select the library containing the entry you wish to rename and tap **Edit Existing Grades.**

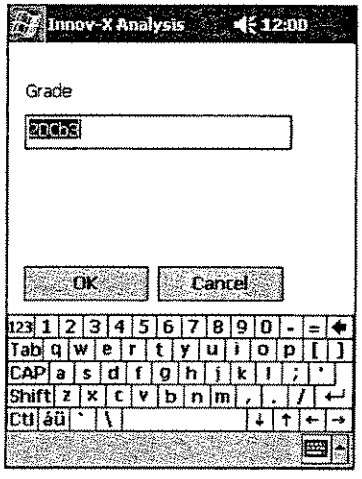


3. A list of the entries contain in the selected library will appear. Select the name to be changed, and click **Rename**. . The name may include any combination of letters or numbers, but may not include the characters /, . , +, _ or ?.

4. You will be prompted for your password.



5. Type the new name in the dialogue box. Select **OK** to accept the new name, or **Cancel** to exit without saving changes.

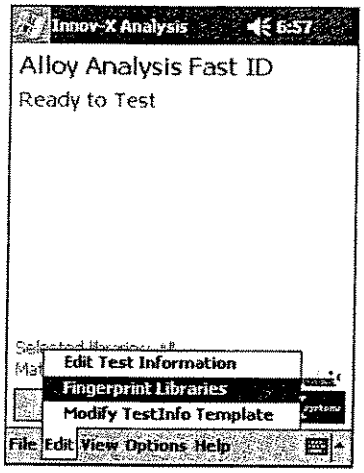


Note, because Grade Table information is stored in Fingerprint files, renaming a fingerprint file will also rename the corresponding Grade Table. However, the reverse is not true. Renaming a Grade Table entry will not rename the fingerprint with the same name. If a grade name is changed, that grade will not be useable in Pass/Fail Mode if **Use Chemistry** is selected.

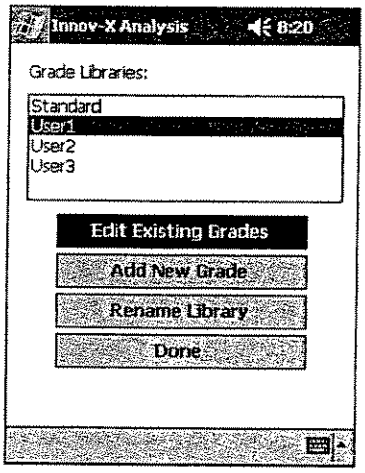
9.5 DELETING A GRADE OR A FINGERPRINT

Caution: Deleting a library entry will permanently delete the Fingerprint and Assay (FastID/PassFail) or the Grade Table (Analytical). Proceed with caution.

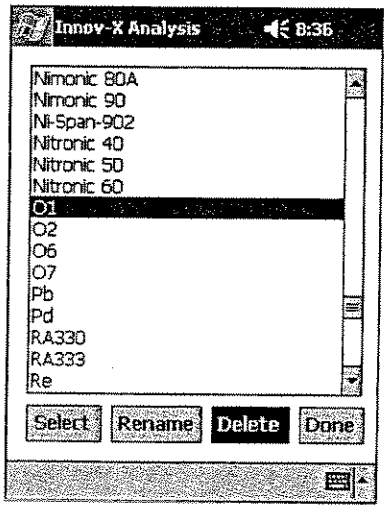
1. From the Analytical Menu, Select ***Edit→Grade Libraries,*** or select ***Edit→Fingerprint Libraries*** from FastID or Pass/Fail.



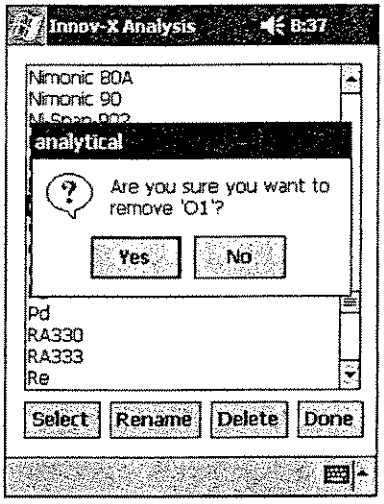
2. Select the library containing the entry you wish to delete and tap **Edit Existing Grades.**



3. Select the sample to be deleted and tap **Delete.**
4. Enter password when prompted.

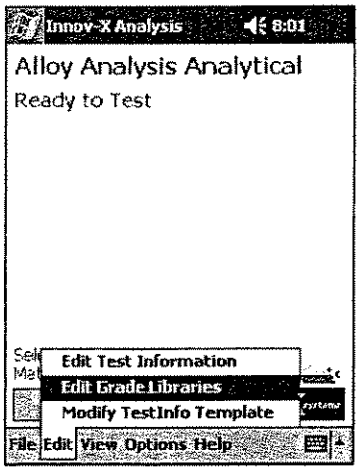


5. You must select **Yes** to confirm deletion. Otherwise select **No**.



9.6 ADDING A GRADE

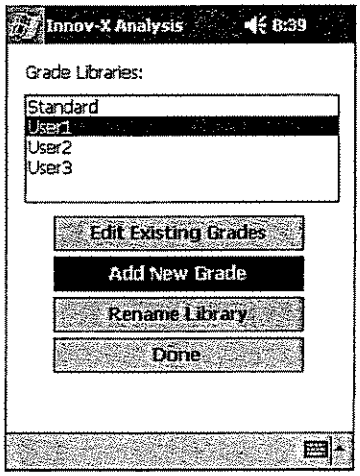
If you wish to add a grade to a library, you must have a list of the minimum and maximum allowable concentrations of each element in the library. It is important to include ALL elements that may be present in an alloy, including the balance element. Pay special attention to tramp elements that may not be specified but may be contained in an alloy of that grade. For example, many stainless alloys may contain small amounts of Molybdenum. If Mo is not included in the grade table, but is detected in sample, the sample may not be correctly identified. In a case like this, it is recommended that a maximum allowable specification is entered, such as 0-.5%.



Follow this simple procedure to add a grade:

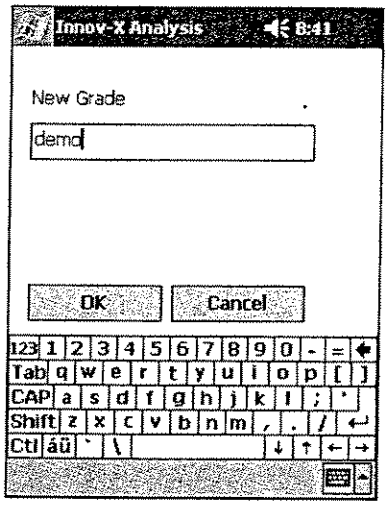
1. From Analytical Mode, Choose **Edit→Grade Libraries.**

2. Select the Library to which you want to add an entry, and tap **Add New Grade.** Enter your password when prompted.

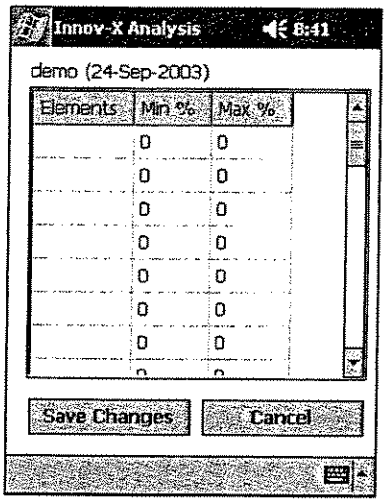


There is a limit of 100 entries in each of the libraries. If you attempt to add a grade to a library which already contains 100 entries, the message "Maximum number of user-defined libraries already exist" will appear. You must either select another library or delete a grade from the current library.

3. Enter the name of the new Grade, and tap **OK**.

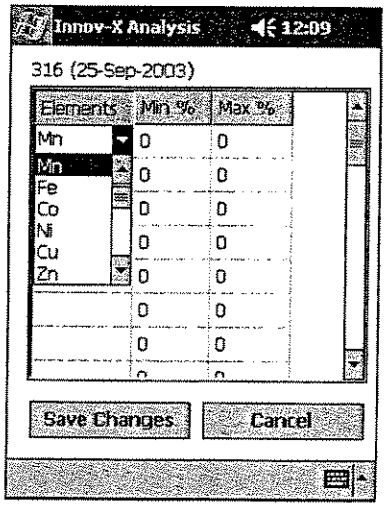


4. A new Min/Max Table will appear. It will contain no elements. A value of zero will be entered for all Min and Max values.



5. To select an element name, click twice in a box in the "Elements" Column of the table. This will bring up a drop down menu.

   You may scroll down an element, or you may advance to a specific element by pressing the first letter of the element on the virtual keyboard. Each time you press a letter, you will go to the next element in the list beginning with that letter. For example, the first time you select M, you will advance to Mn. Selecting M again will advance to Mo.

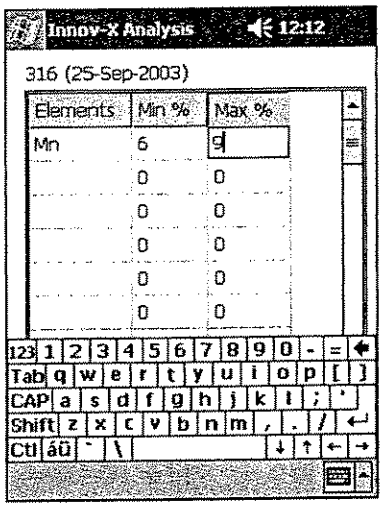


6. To enter a minimum or maximum value, tap in the appropriate space to select it, then enter the desired value.

   a. If an element is listed as being between 6 and 9 %, enter a 6 in the Min % column and a 9 in the Max % column.

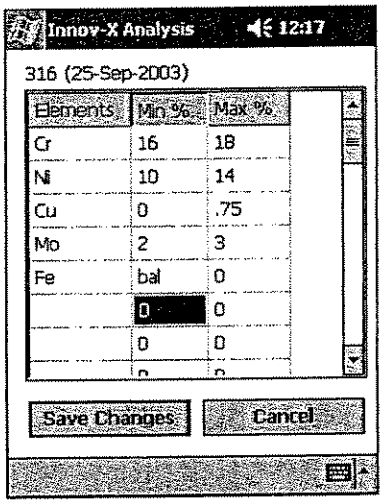
   b. If a maximum value is specified for an element, enter 0 in the Min % column and the maximum specification in the Max % column.

   c. To enter a spec that has only a minimum value specified, enter the value in the Min %column and 100 in the Max %column.

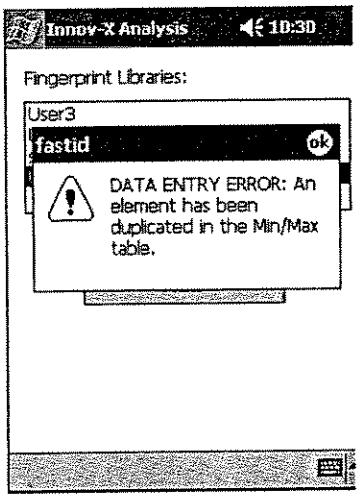


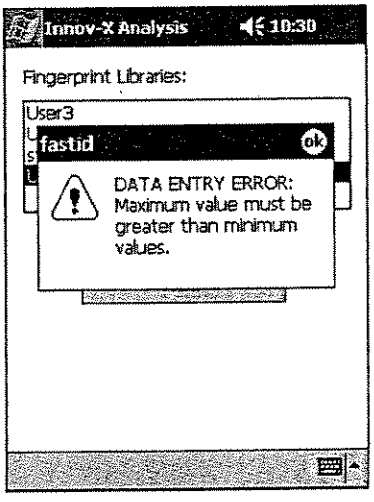
7. Repeat for all relevant elements. Bal may be entered for the balance element.

8. Tap **Save Changes**.



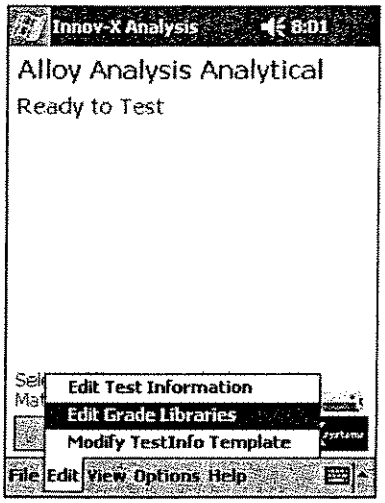
The software requires that the minimum value is less than the maximum value for each element, and that each element is only entered once. If there is a problem with the data entered, a warning message will appear. Click **ok**. The Min/Max table will appear. You must correct any errors before you are allowed to save the data.



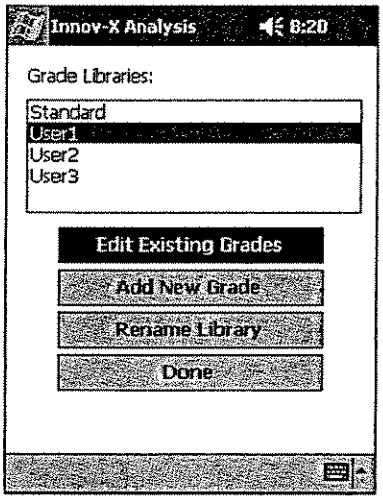


9.7 ANALYTICAL MODE--EDITING A GRADE

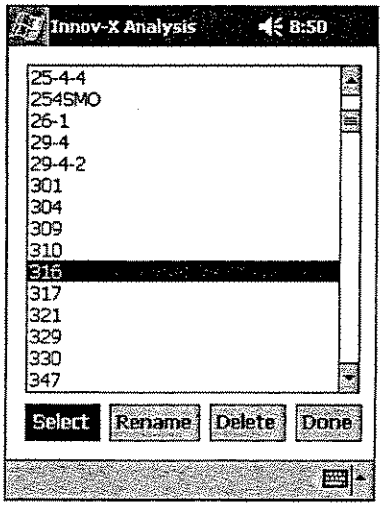
1. From Analytical Mode, Choose *Edit→Grade Libraries.*



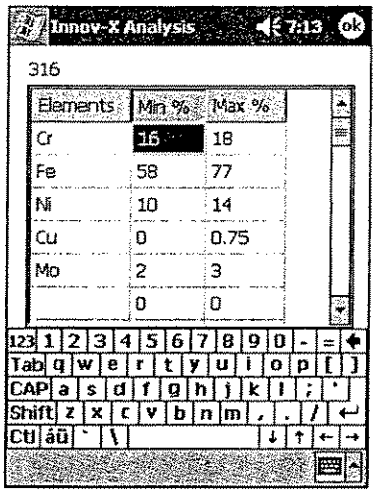
2. Select the library containing the entry you wish to rename and tap **Edit Existing Grades.**



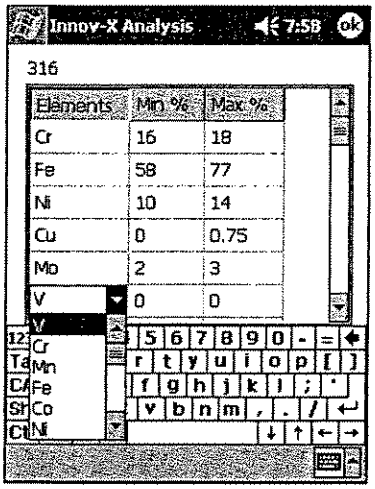
3. A list will appear showing the entries in the library. Tap on the grade name you wish to modify and tap **Select** to bring up the specifications.



4. Element specific minimum and maximum values are shown. Only elements with specified values are shown on the list. To modify min or max values for any listed element, select the appropriate field and enter the new value using the virtual keyboard.

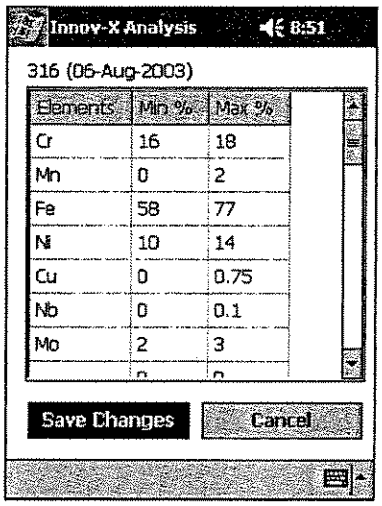


5. To add specifications for an element that is not present, tap twice in an empty box in the Elements column. Use the drop-down menu to select a new element in the field directly below the last listed element.



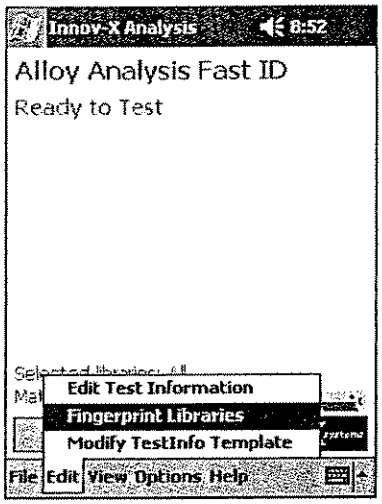
6. Repeat for all relevant elements.

7. Tap **Save Changes**.

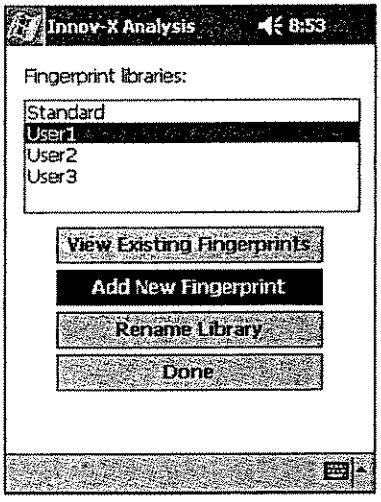


9.8 ADDING A FINGERPRINT

Adding a standard to a fingerprint library requires a sample of the material to use to create a fingerprint. In order to calculate chemistry for this type of alloy, assay values must be available and must be entered into the software. Since assay values are used to calculated chemistries for other alloys, it is important that this information is very accurate. When possible, it is strongly recommended that a certified standard be used.

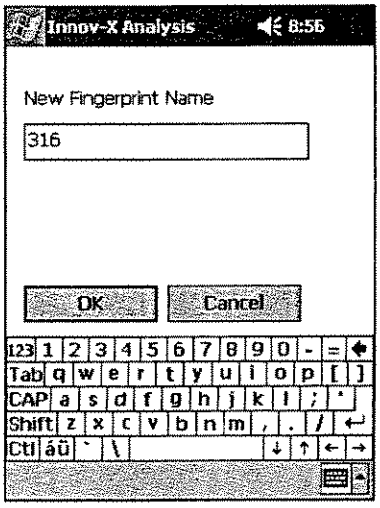


1. From the FastID Analysis Screen, Choose ***Edit→Fingerprint Libraries***.



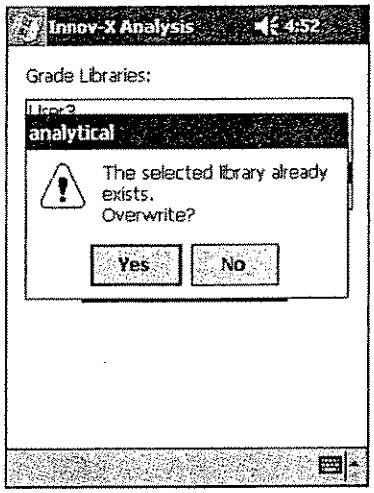
2. Select the Library to which you want to add an entry, and tap **Add New Fingerprint.** Enter your password when prompted. Remember that your password is the lowercase letter **z** unless it has been changed.

The size of the libraries is limited to 300 entries in the standard grade library, and 100 in each of the custom libraries. If the library is full, a message will appear telling you to either delete a grade, or choose a different library.

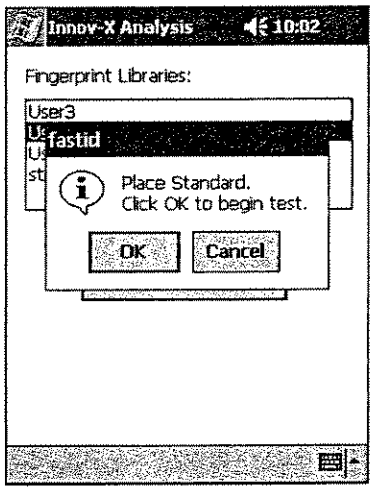


3. Enter the name of the new Fingerprint, and tap **OK**. The alloy name may be any combination of letters or numbers but may not include symbols such as ?, /, ., or +.

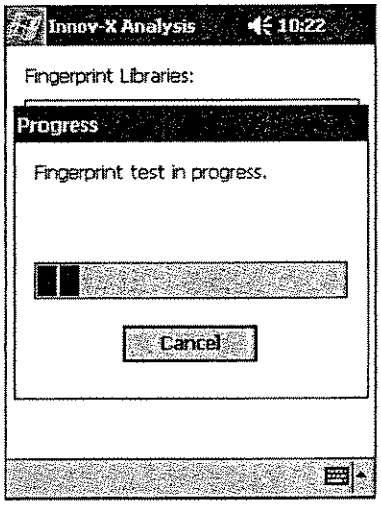
4. If you enter a sample name that is already stored in the library, you will receive a warning message. If you wish to overwrite the existing file tap **Yes,** otherwise select **No** and choose another name.



5. The analyzer will prompt you to place the sample.



6. Place the sample in front of the analyzer window and tap **OK**. The analyzer will acquire a spectrum for storage in the library. The fingerprinting process will take 30 seconds. It is very important that the analyzer window remain in contact with the standard for the entire duration of the fingerprint measurement.

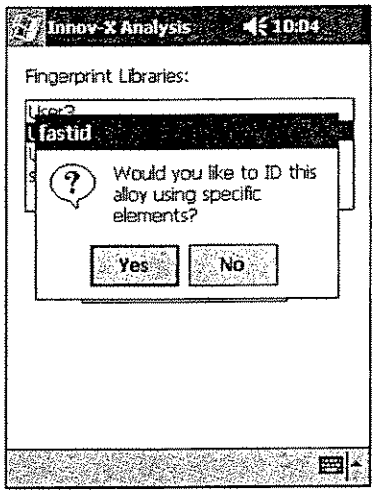


7. When the fingerprint has been stored, you will be asked if you want to enter specific elements.

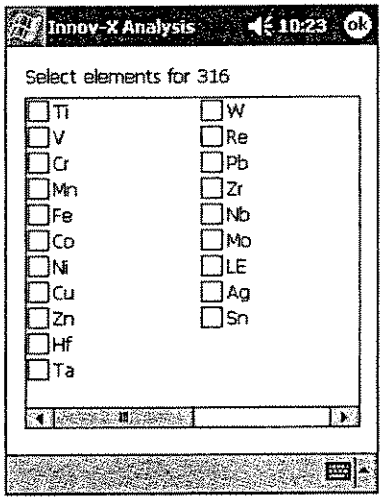
   Using specific elements is described in more detail in the FastID section of this manual. It is useful in situations where you are trying to separate two or more similar alloys that differ only in the composition of one or two elements. Note that this feature is not often used. Most users will select **No**

   If you wish to utilize this function, select **Yes**, otherwise, select **No**.

   If **No** is selected, skip to step number 10.



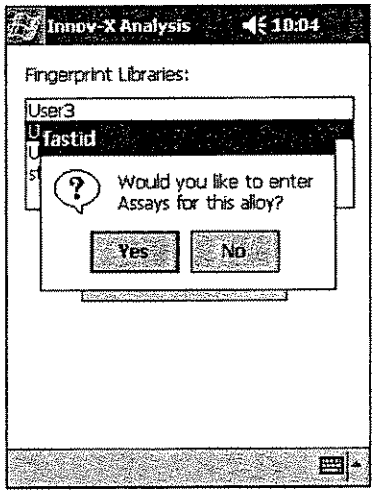
8. To enter specific elements, select the elements you wish to use by checking the box to the left of the element name. Usually, only one or two elements will be selected. Tap **ok** when you are finished



9. After specific elements have been selected, or after selecting **No** in step 8, you will be asked whether you want to enter assays.

   In order for the Innov-X Systems Software to calculate chemistries in FastID or Pass/Fail Modes, assays must be entered.

   If you do not wish to enter assays, or they are not available, select **No**. If you select **No**, you will be able to use this Fingerprint for Grade Identification in FastID, and using the **Fingerprint** method in Pass/Fail. However, it will not be possible for the instrument to calculated chemistries for alloys matching this fingerprint. Skip to step 12 if **No** is selected.



10. A blank table will appear. Enter the element name and assay into this table.

    a. To select an element name, click twice in a box in the "Elements" Column of the table. This will bring up a drop down menu. Scroll down to the element you wish to select, or select the first letter in the element symbol using the keyboard.

    b. Enter the assay for the selected element in the next column.

       The software will automatically calculate the value of a balance component if "bal" is typed into the percentage column.

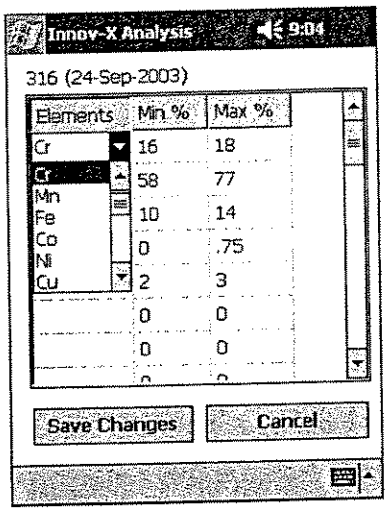
       Keep in mind typical detection limits of the instrument when entering assays. As a general rule, do not enter assays which are below 0.3%.

    c. When all assays have been entered, tap **Save Changes**.

11. After entering assays (or if no was selected in step 10), the system will ask if you want to enter Min/Max ranges. This is recommended only if you will be using both Analytical and FastID to identify this standard alloy, or if you will be using Pass/Fail mode with **Use Chemistry** activated. The vast majority of users will select **No** in answer to this question.

    If you wish to enter Min/Max ranges, select **Yes**; otherwise select **No**. If you select **No**, the process of entering a fingerprint is complete.

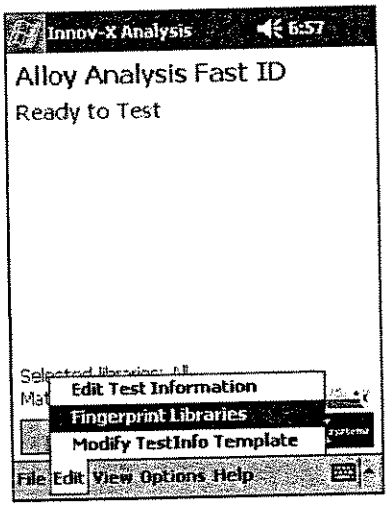
12. Enter your Min and Max ranges for each of the elements in your sample. If you have any questions about this procedure, you can refer to the description in **Section 9.6: Adding a Grade.**



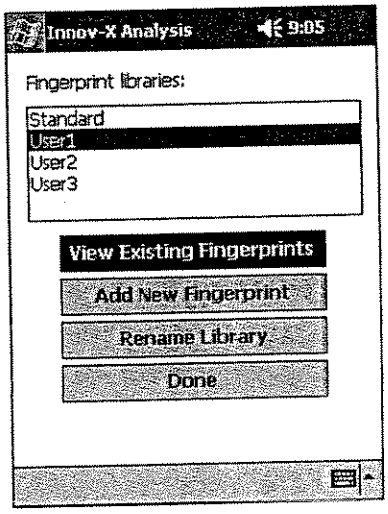
9.9 EDITING FINGERPRINT LIBRARIES

It is possible to edit Assays, Specific Regions and Min/Max (Grade Tables) for existing elements.

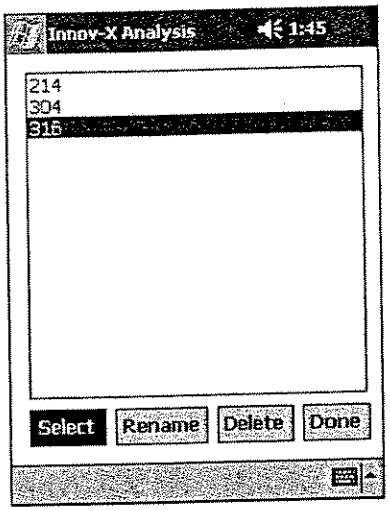
1. From the Fast ID Analysis Screen, Choose ***Edit→Fingerprint Libraries.***



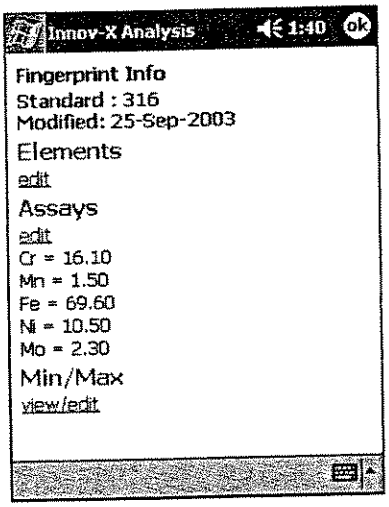
2. Select the Library containing the fingerprint you want to modify and select **View Existing Fingerprints.**



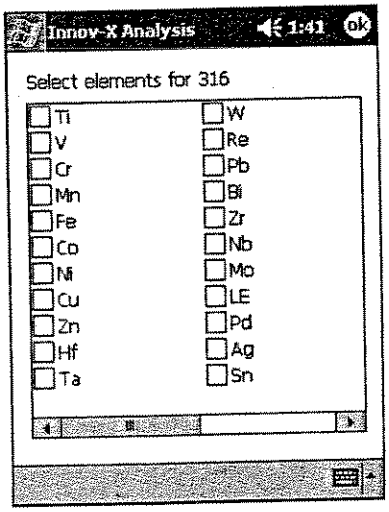
3. A list will appear showing the entries in the library. Tap on the grade name you wish to modify and tap **Select** to bring up the specifications. Refer to the **Section 9.8: Adding a Fingerprint** for more information on any of these features.



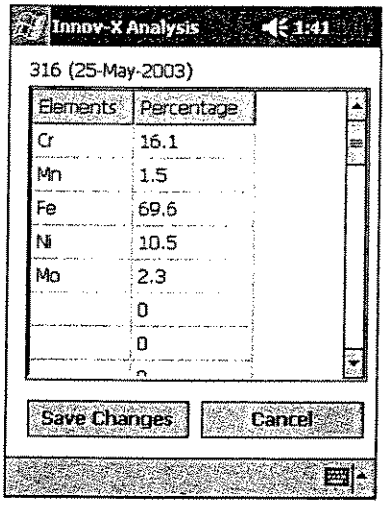
4. The fingerprint info screen will be selected. If any assays are stored with the fingerprint, they will be shown here. To edit, tap the words **edit** or **view/edit** below the information you wish to enter.



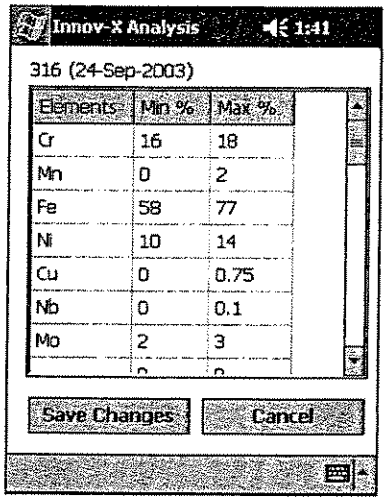
5. Editing elements brings up the specific elements screen. Select elements you wish to use. Press **ok** to select.



6. If you wish to enter assays, enter the elements contained in the sample and the certified values.



7. Min/Max **View/Edit** allows you to enter minimum and maximum specifications for each element.



5.0S Soil Analysis

The Innov-X analyzer can be used to analyze in situ (directly on the ground), bagged or prepared soil samples. A guide to Soil analysis using field portable X-ray fluorescence is found in the appendix. This document summarizes EPA Method 6200 which is the standard protocol for field screening. It also provides information on prepared sample testing.

5.0 CHECK STANDARDS

It is recommended that a check standard is measured after each standardization, and periodically throughout the day. Innov-X provides several NIST certified standards for verification. The certified values for these samples are provided in the appendix. At least one standard should be measured for a minimum of 1 minute. Elemental concentrations for elements of interest plus or minus the error on the reading should be within 20% of the standard value. The Field screening guide in the appendix describes in more detail recommended quality assurance considerations.

The standards provided with the XRF analyzer are contained in XRF sample cups with a Mylar window (through which the soil can be viewed) on one side, and a solid cap on the other side. Samples should be measured in the sample cup, through the Mylar window. The best way to measure a prepared sample is using the test stand. If this is not available, the sample may be placed on the ground, and the analyzer may be pointed downwards in full contact with the soil cup. Do not hold the soil cup in your hand while measuring.

5.1 SAMPLE PRESENTATION

In situ testing:

In situ testing is performed by pointing the analyzer at the ground. Any grass or large rocks should be cleared away and the analyzer should be held such that the front of the probe head is held flush to the ground.

Since dirt can accumulate on the analyzer window, it is recommended that the window is wiped clean after each analysis. The window should also be checked to ensure it is not ripped or punctured. Instructions for replacing the window are found in the appendix.

Bagged or prepared sample testing:

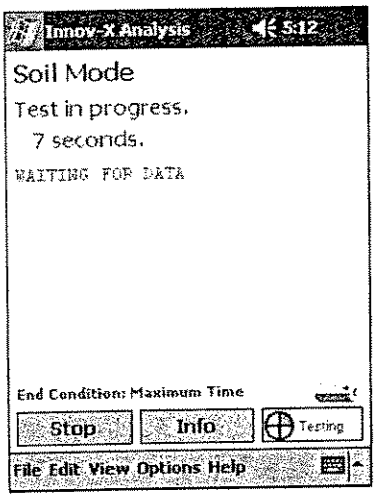
It is strongly recommended that all prepared samples be analyzed in the testing stand. Samples should be placed on top of the testing stand, completely covering the window. **Never hold prepared or bagged samples while testing,** as this could expose the operator to the x-ray beam.

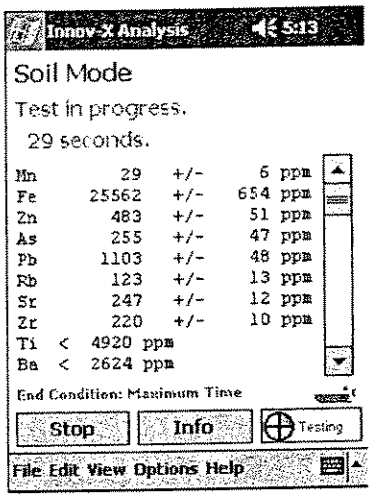
Avoid measuring very thin samples, as this can affect results. Prepare samples cups to contain at least 0.5 inches of packed samples. When analyzing bagged samples, make sure that sufficient sample exists in the bag to completely cover the window with a sample thickness of a minimum of 0.5 inches.

5.2 TESTING IN SOIL MODE

After the instrument has been standardized, testing can begin. Simply pull the trigger or press **Start** on the iPAQ screen to begin the test. The red warning light on the top of the instrument will blink, indicating X-rays are being emitted. The screen will display the words "Test in progress" and the time elapsed. The word "Testing" will blink on and off in the low right hand corner of the screen.

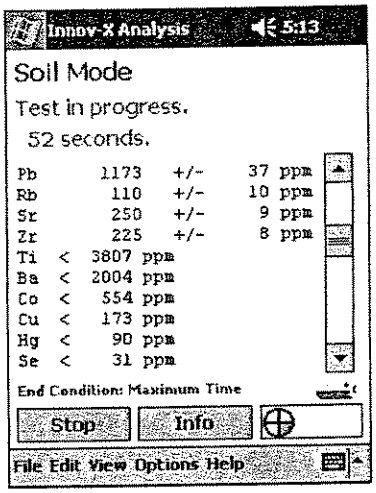
After a minimum time has elapsed, intermediate results will be displayed on the screen. Until this minimum time has elapsed, the words "WAITING FOR DATA" will appear instead. This minimum time can be set by the user by selecting ***Options→Set Testing Times***, which is described in **Section 5.4: Soil Mode Options.** Each line of the results display shows the name of an element, its calculated concentration and the error on the measurement. This error is the 1 sigma error on the counting statistics of the measurement. The error will decrease with increased testing time.





Too many elements are measured in soil mode to display them at one time. However, is possible to use the scroll bar located to the right of the chemistry display to view other elements. The complete display shows detected elements first, listed in order of emission line energy, from lowest to highest. Following the detected elements are the elements which are below the detection limit of the instrument. These elements are shown as less than a calculated LOD. This LOD is defined as three times the error on the counting statistics of the measurement.

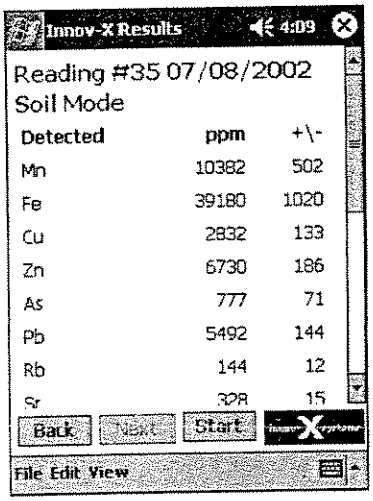
When the measurement is complete the results screen will open, displaying the final results of the measurement.

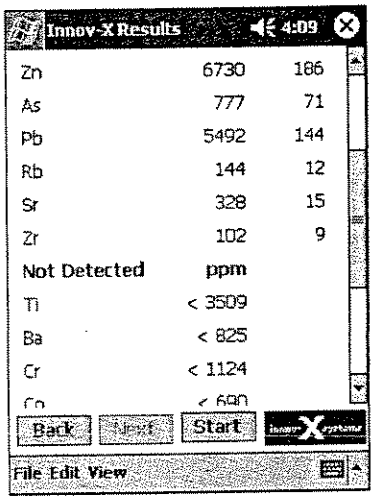


5.3 SOIL RESULTS SCREEN

5.3.1 Results View Menu

The standard Soil Mode results screen displays the concentration (in ppm) and error in measurement for detected elements, followed by the list of non-detected elements with the calculated limit of detection for each element for that test. If the display does not show soil chemistry results, change the display by selecting ***View→Results.***



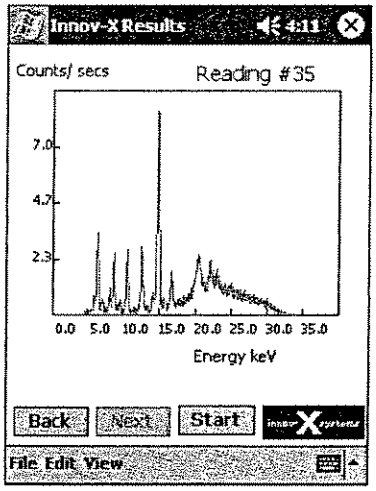


The standard soil chemistry display can be modified by using the View Menu. As with all Innov-X analytical modes, it is possible to view spectra and Test Information.

5.3.2 Spectrum Screen

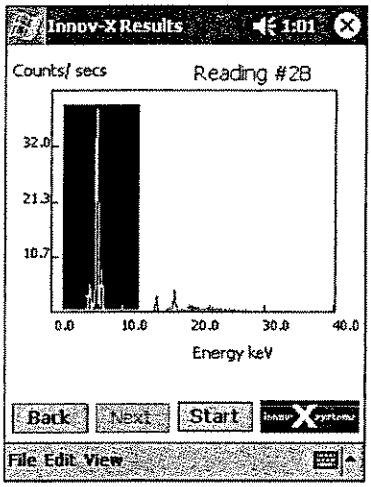
This screen displays a plot of the x-ray fluorescence spectrum for an individual test, plotting the intensity on the y-axis versus the energy of the fluorescence x-rays on the x-axis.

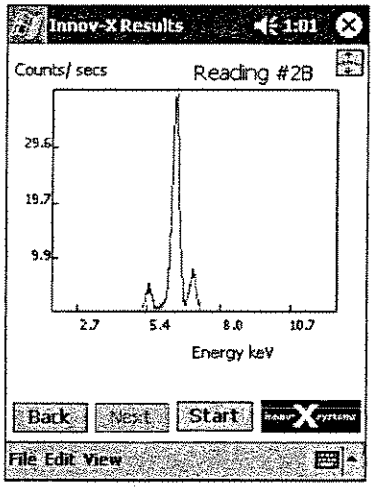
Tapping on the spectra will show the energy scale and counts rate at the selected point



It is possible to zoom in on certain areas of the graph by selecting one corner and drawing out the region

Tapping the symbol in the upper right hand corner beneath the X will restore the graph to full scale.





5.3.3 Test Info Screen

The test information screen shows any test information that was entered prior to the start of the test. Changes to that test information can be made by selecting **Edit→Test Information.**

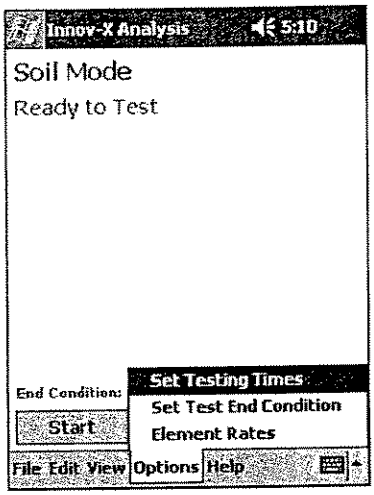
5.4 SOIL MODE OPTIONS

The length of tests in Soil Mode is user settable. Users may select a minimum testing time, and as well as choose from a variety of test end conditions.

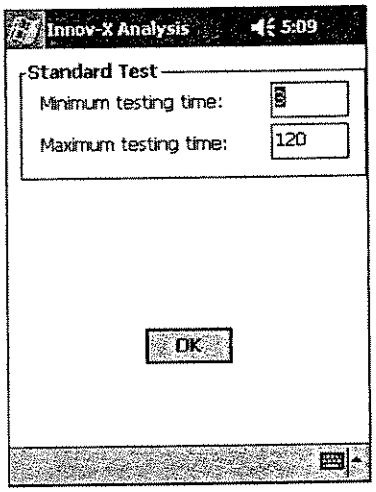
The options related to test time are contained in two menus: ***Options→Set Testing Times***, and ***Options→Set Test End Condition. Set Testing Times*** contains minimum and maximum testing time information, while ***Set Test End Condition*** allows the user to select test end conditions.

5.4.1 Set Testing Times

To set the minimum and maximum test lengths, select **Options→Set Testing Times**



A screen appears prompting you to enter a Minimum and Maximum Testing times. Instruments equipped with the optional LEAP package will be able to set Light Element Testing times in this screen, as well.



The minimum testing time is the required time that must elapse before results can be calculated. Live Update results will not be displayed on the screen until the minimum has elapsed, likewise a test must complete the minimum time before any test end condition can be used. If a test is stopped before the minimum testing time has elapsed, the test will be aborted, and no results will be calculated.

Maximum testing time is relevant only if "Maximum Testing Time" is selected from **Set Test End Condition**. This will automatically end the test at a preset testing time. Typically, the maximum testing time will be in excess of 30 seconds, and may be 1 or 2 minutes, depending on detection limits and desired precision.

It should be noted, that all testing times in this section refer to "Real Time," the time the measurement takes when timed on a normal clock. The time stored with each analytical result (accessible by selecting **View→Test Information** from the Results screen), refers to the test's "Live Time". This is the amount of time that the analyzer hardware was collecting spectra. Since there is some detector dead time associated with a measurement, the live time of a test will be slightly shorter than the preset "Real time".

5.4.2 Soil Mode Test End Condition

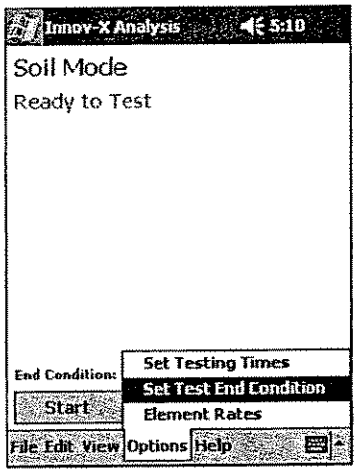
Four options exist for the test end criteria in soil mode. Depending on your application, you may choose to end the test manually, at a preset testing time, or when the uncertainty in the measurement is within a

specified relative standard deviation of the reading. Additionally, you can set up an action level for a single element. As soon as the measuring statistics are good enough to ensure that that the reading is above, below or at the action level, the test will end automatically. This allows for very rapid tests for elements that are well above or below an action level.

In all modes, pressing Stop, or pulling the trigger will end the test. If the minimum testing time has elapsed, results will be calculated. Otherwise the test will be aborted without calculating results.

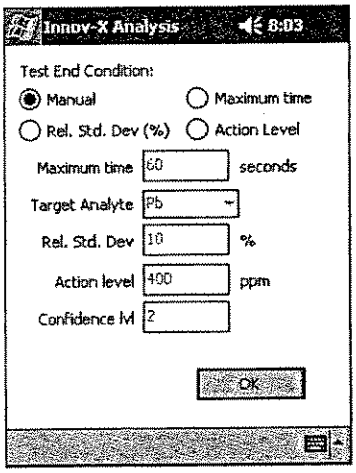
Changes to the test end condition are made by selecting ***Options→Set Test End Condition***

The currently selected end condition will be displayed at the bottom of the screen above the Start button on the Ready To Test screen.



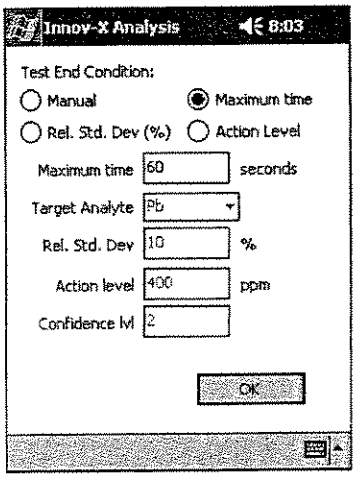
Manual: This option allows you to look at the results which are being continually updated on the screen and determine when the results look satisfactory. The test will continue until the trigger is pulled, or **Stop** is tapped on the iPAQ screen. Results will be calculated if the testing time has exceeded the Minimum Test time which is set up in ***Options→Set Testing Times***. In order to preserve battery life, the software will stop if the testing time exceeds 300 seconds, since there is little to no advantage to continuing a test beyond 300 seconds.

To use Manual Test End Condition, simply choose ***Options→Set Test End Condition*** and select **Manual**. Press **OK** to return to the analysis screen.



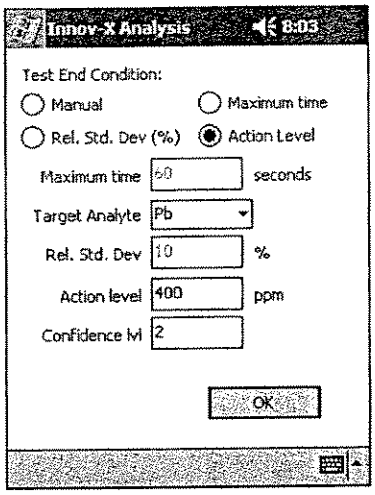
Maximum Time: If Maximum Time is selected, the test will continue until the preset time is reached. This is useful if you wish to do a set of measurements with the same testing time.

To choose to end test based on a maximum time, select ***Options→Set Test End Condition*** and select **Maximum Time**. Enter the desired testing time in the appropriate box. Tap OK to save your selections.



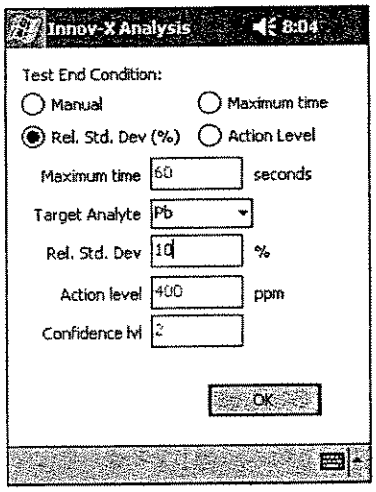
Action Level: System ends test when result for target analyte including chosen precision level is above or below pre-set action level.

To choose to end a test based on an Action Level, select ***Options→Set Test End Condition*** and select **Action Level**. Select a target analyte, specify an action level in ppm, and a confidence level. This confidence level refers to the number of sigma required for the precision. This should typically be set to 2. Tap **OK** to save your selections.



Relative Standard Deviation (RSD): When RSD is selected as a test end criteria, the system will end a test when the relative standard deviation on a target analyte reaches a pre-set level. This standard deviation is specified as a percentage of the reading. For example, if the measured value for an analyte was 1000 ppm, and the RSD was set to 10, the reading would stop when the error reached 100 ppm, or 10% of 1000.

To choose to end a test based on a Relative Standard Deviation, select ***Options→Set Test End Condition*** and select **Rel. Std. Dev (%).** Select a target analyte and the desired Relative Standard Deviation. Tap **OK** to save your selections.



5.5 LEAP Mode (Light Element Analysis Program):

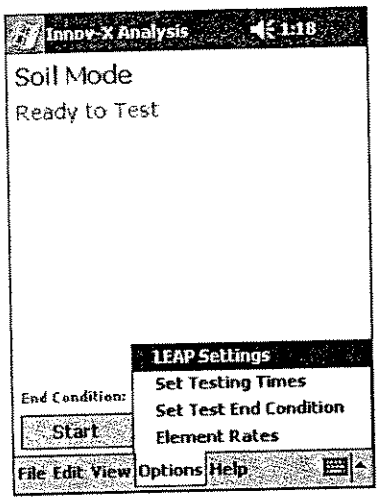
This is a factory installed optional module. Instruments can be upgraded to LEAP capabilities. Please contact the Innov-X Systems Sales department for information and pricing.

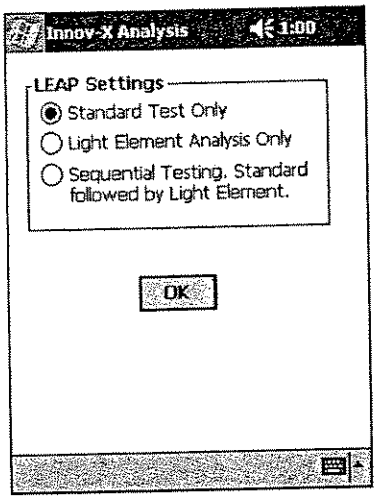
The LEAP module provides the lowest possible detection limits for elements lighter than iron. The standard LEAP package includes the elements Ti, Ba and Cr. Elements as low as Phosphorus can be detected with the Advanced LEAP package which includes a thin window detector.

The standard x-ray beam conditions used by Innov-X environmental analyzers are designed to provide good excitation for a wide range of detected elements. However it is not possible to select one beam condition which provides the absolute best excitation conditions for all elements of interest. Elements such as Chromium produce lower energy x-rays then other elements analyzed. These lower energy x-rays are not as effectively excited by the standard conditions. LEAP works by changing the X-ray tube beam conditions to settings which are optimized for the detection of elements lighter than iron. Instruments are factory calibrated with the LEAP beam conditions for all applicable elements.

5.5.1 LEAP Settings

To activate LEAP, select ***Options→LEAP Settings*** from the Soil analysis screen. This brings up the menu shown below on the right.



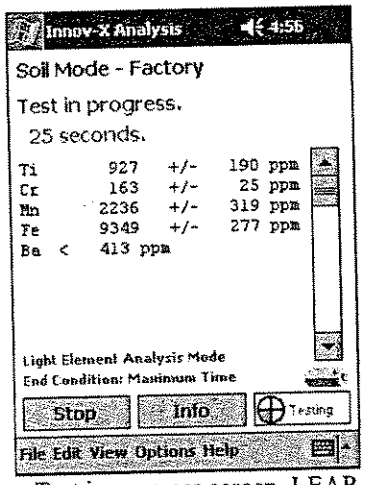


Standard Test Only: The analyzer will provide analysis for the standard suite of elements.

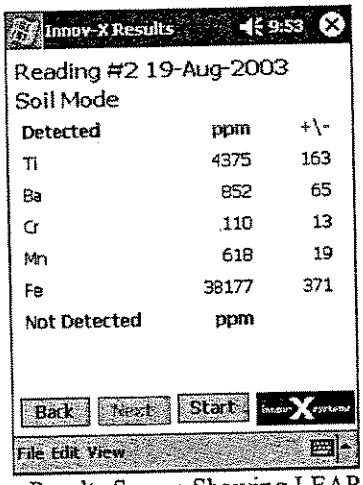
Light Element Analysis Only: The analyzer will provide analysis for elements in the LEAP suite (Typically Ti, Ba and Cr)

Sequential Testing: When sequential testing is selected, all tests will start with an analysis of elements in the standard suite. If that test ends due to reaching the selected end condition of Maximum Test Time, Action Level, or RSD, then the analyzer will immediately begin a second test analyzing the LEAP suite of elements. At the conclusion of this test, the Results screen will open with two new entries. The first summarizes the standard test results, while the second summarizes the LEAP results. For safety reasons, the second test will not begin if the test ends due to user intervention (pulling the trigger or hitting Stop). In this case, the Results screen will open with only one reading.

If Light Element Analysis Only is activated, the words "Light Element Analysis Mode" will appear above the currently selected End Condition. Instrument operation in this mode is identical to Standard (Non-LEAP) analysis. Tests can be started or stopped either by pulling the trigger, or by tapping the Start/Stop button on the iPAQ screen. The results screen for a test will show results for all elements analyzed with the LEAP mode.

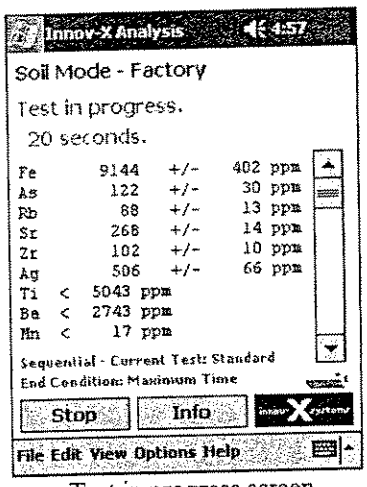


Test in progress screen, LEAP Only, Live Updates on

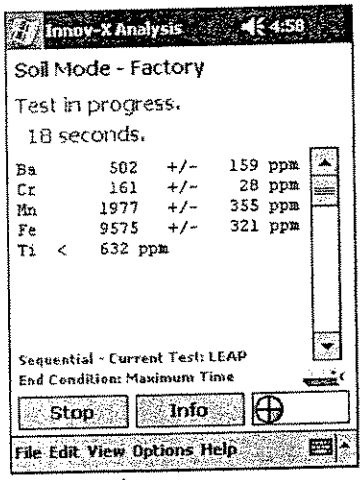


Results Screen Showing LEAP results

If Sequential testing is selected, the words "Sequential – Current Test: Standard" will appear above the currently selected End Condition. When a test is started, the instrument will appear to operate in the same manner as a Standard test. However, if the test ends according to the specified end condition (excluding Manual), the results screen will not open. Instead, the timer will reset to 0, and the description of the current test will change from "Standard" to "LEAP". The live update screen will begin to show analysis for all LEAP elements.



Test in progress screen, Sequential.
First Test – Standard Analysis.

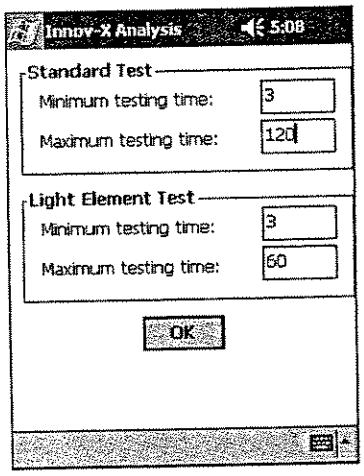


Test in progress screen, Sequential.
Second Test – LEAP Analysis

5.5.2 Testing Times

To set the minimum and maximum test lengths for LEAP analysis, select **Options→Set Testing Times.**

The testing time screen includes an extra section labeled "Light Element Test" that is not found on non-LEAP systems. These are the minimum and maximum test lengths for any LEAP tests.



As with standard tests, the minimum testing time is the required time that must elapse before results can be calculated. Live Update results will not be displayed on the screen until the minimum has elapsed, likewise a test must complete the minimum time before any test end condition can be used. If a test is stopped before the minimum testing time has elapsed, the test will be aborted, and no results will be calculated.

The Standard Grade library holds 250 alloys with specifications. Three additional user libraries are available, each hold 100 alloys. Users may edit all libraries entries and may add or delete grades and fingerprints.

Appendix 3: Troubleshooting Guide—Alloy Analysis

Problem	Possible Solutions
Software won't start: Software will not start when the Innov-X Systems Icon is tapped.	The flash card or the iPAQ may not be correctly seated in the black external sleeve. Remove the flash card and press it firmly into its holder. Press the iPAQ down into the black sleeve.
Software won't start: Software doesn't start when the Innov-X System icon is tapped; instead, the following error message occurs: "Cannot find 'startup' (or one of its components). Make sure the path and filename are correct and all the required libraries are available"	The flash card or the iPAQ may not be correctly seated in the black external sleeve. Remove the flash card and press it firmly into its holder. Press the iPAQ down into the black sleeve.
IPAQ locks up: iPAQ screen "locks up" and doesn't respond when screen is tapped or buttons are pressed	Remove the iPAQ from the analyzer and perform a soft reset by pressing the tip of the stylus into the small indentation found on the bottom of the iPAQ. If the iPAQ is lying flat on a table with the screen facing upwards, the reset button is found to the extreme right of the side containing the power plug and connector. See Page 4 of the Compaq "Getting Started" manual for an illustration showing the location of the reset button.
Analyzer will not standardize	Try again. Choose File -> Standardize to attempt a new standardization. Also be sure the standardization cap is on correctly, and that the solid half is in front of the window. It is OK to try this 2-3 times in the event of a failure. If a repeat attempt fails: Change the battery. In some cases the battery may be too low to provide enough power for tube startup. Follow this procedure: • Reset the iPAQ; • Turn off the analyzer and remove the battery. • Verify that the battery is completely charged. If it is not, replace it with a fresh battery. Even if the battery has been recently recharged, remove it, and replace it in the analyzer. • Restart the analyzer and software. Wait several minutes after the software has initialized before attempting standardization.
Incorrect Alloy ID in FAST ID Mode: Analyzer does not correctly ID sample that was just added to the library in FastID.	Verify that the Alloy was saved in a library which is being searched. ***Use File→Load libraries*** to change the library being search. ***Edit→Fingerprint libraries*** "Show/Modify" can be used to check that the fingerprint was saved in the proper library.

Analyzer gives "No Match" for every sample.	1. Verify that Match Numbers are set to 1 for Fast ID and 3 for Analytical. Change values by selecting ***Options→Fingerprint Setup*** from the Analysis screen for FastID mode, or ***Options→Grade Library Settings*** **from Analytical mode.** 2. Verify that you are searching the correct library. Use ***File→Load Libraries*** to change the library being searched. Most users should search all libraries. 3. Check to make sure that the analyzing window is clean.
All tests yield incorrect match	Check the date and time on the last result shown. It should show the current date. If it doesn't, check the date on the iPAQ. The Innov-X Systems software indexes stored results by date. If the date is incorrect, results may not be displayed in the correct order.
Results screen doesn't show new readings after a test is completed	Check the date on the iPAQ. The Innov-X Systems software indexes stored results by date. If the date is incorrect, results may not be displayed in the correct order.
Serial Communication Error Message: Serial Communication error occurs because iPAQ has been removed from instrument or cradle, with the software open and the instrument standardized.	This error reflects the temporary loss in communications when the iPAQ was removed. To avoid this problem, always use the **File→Exit** command to exit the software properly. Try simply removing and reseating the iPAQ to solve this problem. If that fails, see steps 1 – 4 below.
Serial communication error on startup, or while testing.	1. If the analysis screen is still open, attempt another test. 2. Verify that the iPAQ is correctly seated in the analyzer by removing and replacing it. 3. Remove the iPAQ and perform a soft reset. Replace iPAQ and restart software. 4. Turn the analyzer off and restart it.
Trigger will not start test.	Verify that the trigger lock is off. Reset the instrument. If this fails, call Innov-X Systems Technical Support at 781-938-5005.

Broken Kapton Window	The window is designed as a barrier to dust and dirt. If it is damaged, it should be replaced. To change the window: Turn off the analyzer Remove the screws holding the front plate in place. Remove the old kapton and adhesive, replace with new kapton and replace front plate. **Important Note:** It is very important to avoid getting dirt and sharp objects within the probe, due to the close proximity of the detector. Do not use the analyzer without a kapton window for any length of time. Also, be very careful when removing/replacing screws in face plate so as to not accidentally damage the detector. If the detector is damaged, the instrument will require factory service.

Appendix 4: Guide to Product Registration

Generally, the Innov-X portable XRF system must be registered in the state of usage. Registration requirements are somewhat state dependent, but there are many similarities. You may contact Innov-X at 866-4-Innov-X (781-938-5005) to receive specific registration information. Innov-X also maintains sample registrations for every state that we can forward to you. Outside the United States, our local sales agents provide guidance in the proper registration of the analyzer.

Common Registration Features:

Most states require the following for registering an x-ray emitting device that does NOT use radioactive sources:

1. Registration within 30 days of receipt of the analyzer.
2. Annual fee in the $25 to $200 range, depending upon the state.
3. Basic registration form with main information described below.

Common information required on Registration Form, and responses:

Company name, address, phone/fax numbers.

Name of responsible person:	Generally the person designated as the Radiation Safety Officer (RSO).
Name of the manufacturer:	Innov-X Systems, Inc., Woburn, MA
Model of Analyzer:	XT-220 or XT-260.
Tube Operating Parameters:	35 kV, 20 uA current.
Type of Analysis:	Choose Analytical or Industrial
	(as opposed to radiography, medical, dental, veterinarian, etc.)
Utilization Mode:	Portable or Mobile assuming you will carry system to different locations.
	Fixed or stationary ONLY if you will always use the analyzer in the docking station

Appendix 1: Troubleshooting Guide—Soil Analysis

Problem	Possible Solutions
Software won't start: Software will not start when the Innov-X Systems Icon is tapped.	The flash card or the iPAQ may not be correctly seated in the black external sleeve. Remove the flash card and press it firmly into its holder. Press the iPAQ down into the black sleeve.

Verify that the iPAQ is correctly seated in the analyzer by removing and replacing it. 3. Remove the iPAQ and perform a soft reset. Replace iPAQ and restart software. 4. Turn the analyzer off and restart it.

esults take a very long time to display on the first test of the day.	There may be too many readings stored in memory. Erase readings from the results screen by selecting ***File → Delete Readings***.
Trigger will not start test.	Verify that the trigger lock is off. Reset the instrument. If this fails, call Innov-X Systems Technical Support at 781-938-5005.
Broken Kapton Window	The window is designed as a barrier to dust and dirt. If it is damaged, it should be replaced. To change the window: Turn off the analyzer Remove the screws holding the front plate in place. Remove the old kapton and adhesive, replace with new kapton and replace front plate. **Important Note:** It is very important to avoid getting dirt and sharp objects within the probe, due to the close proximity of the detector. Do not use the analyzer without a kapton window for any length of time. Also, be very careful when removing/replacing screws in face plate so as to not accidentally damage the detector. If the detector is damaged, the instrument will require factory service.
Results screen shows message "Error in calculation: No Results"	The soil mode calculation is only valid for "soil-like" samples which contain primarily light elements such as carbon, oxygen and silicon. If a dense, highly metallic sample is analyzed, the calculation fails. Make sure the sample being analyzed is a soil sample, if it is and this message occurs repeatedly; call Innov-X technical support.

Appendix 2:

Metals in Soil Analysis Using Field Portable X-ray Fluorescence

A guideline to using portable XRF according to EPA Method 6200, basic overview of the technique of x-ray fluorescence (XRF), appropriate data quality assurance protocols and sample preparation steps for operators analyzing prepared soil samples.

Prepared by:

Innov-X Systems, Inc.
January, 2003

Section 1: Regulatory Status for Field Portable XRF

EPA Reference Method 6200 has been incorporated into SW486 under RCRA, and is now available for field portable XRF analysis of soils and sediments. Please call or email Innov-X Systems for a copy of Method 6200.

Method 6200: Field Portable XRF Spectrometry for the Determination of Elemental Concentrations in Soil and Sediment.

Features of this method:

1. It is a field screening method, for analysis of *in-situ* or bagged samples.
2. The method provides basic quality assurance methods, including calibration verification, determination of instrument precision, accuracy and limit of detection.
3. The method recognizes the some XRF instruments do not require site-specific calibrations by the operator, that is, the factory calibration provides appropriate data quality.
4. The method recommends that a minimum of 5-10% of samples tested by XRF be confirmed by an outside laboratory using a total-digestion EPA analytical reference method.

The purpose of EPA Method 6200 is NOT to replace laboratory analysis. There are two primary sources of error in assessing a site for metal concentration: **Analytical error** and **Sampling error**. Analytical error is the error in the analysis of any one sample by whatever technique is used, for example XRF, ICP, or AA. Sampling error arises when too few samples are collected and tested. In this case an incomplete picture of the extent of metals contamination may be obtained. Although any one sample may be analyzed with very high analytical accuracy, measuring too few samples may result in contamination plumes being mis-judged in size, or depth into the soil. In extreme cases contamination may missed entirely.

EPA Method 6200 was developed to reduce Sampling Errors by increasing the number of samples measured. In general, a large number of screening-level measurements provide a better characterization of contamination than a small number of measurements produced by sample removal and analytical analysis. Portable XRF is an ideal tool to make a large quantity of measurements in a short period of time. A large number of in-situ samples provides detailed data on contamination profiles, depth (provided surface soil is moved aside), and approximate contamination levels. Portable XRF also can provide results with a high degree of analytical accuracy on any given sample. Please see Section 2 "Overview of Field Usage" for this discussion.

Section 2: Overview of Field Usage:

Field portable XRF is generally used in three ways to test for metals in soil:

- **In-situ soil testing:** The XRF is placed directly onto the ground for soil testing. Operators remove any plant growth and foreign objects so that the analyzer probe is flush to the soil.
- **Bagged soil sample testing.** A soil sample is collected in a thin plastic bag (i.e. a "Baggie") and testing directly through the Baggie. Except for a few elements – namely Cr, V and Ba – testing through the thin plastic used for a plastic bag has little effect on the test result. Results for Cr, V and Ba will be lower by 20-30%.
- **Prepared soil sample testing.** Prepared sample testing assures the operator of the maximum possible accuracy. Prepared sample tests require a sample to be collected, dried if necessary, sieved and ground into a powder. The prepared sample is then placed into a baggie or XRF cup for analysis. **A complete Soil Preparation Guide is provided in Appendix 1.**

All analytical methods require a uniform, homogenous sample for the best results. **XRF is no different!** The methods described in EPA Method 6200, namely In-situ and bagged sample testing, are considered *field-screening methods*. Although a field-screening method, in-situ testing is a valuable technique because it generates a great deal of data very quickly. Prepared soil samples generally offer the best accuracy, albeit with several minutes of sample preparation required per sample.

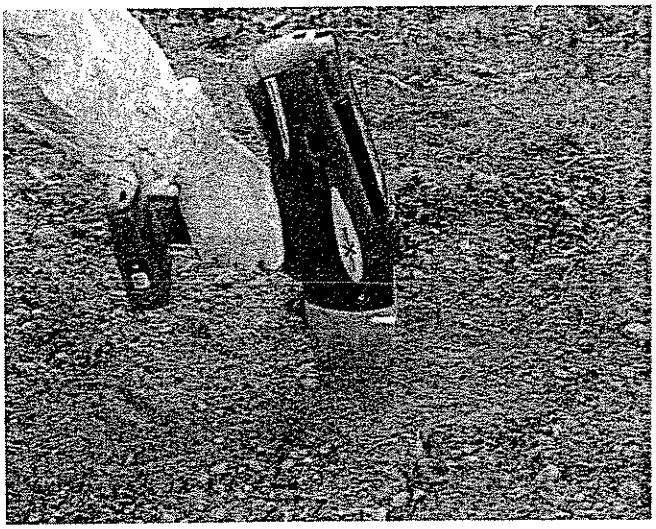

Figure 1. Use of a field portable XRF for in-situ soil testing.

Subsection 2-A: Data Quality Objectives.

The objectives of the testing generally determine the mixture of in-situ versus prepared sample testing. It is important to understand your data quality objectives (DQO) in order to determine the appropriate mix of field screening and prepared sample testing.

In-situ testing usually provides only screening-level data quality. This is because analytical testing always requires a uniform, homogeneous sample matrix. A laboratory achieves this by digesting the sample into a hot acid before analysis. Testing directly on the ground does not ensure uniformity is met. Preparing a sample provides a uniform sample and likely better analytical data quality, although several minutes of testing time is required.

Most portable XRF operators use a mixture of in-situ and prepared sample testing. Several examples are described below. The exact mixture of in-situ and prepared sample testing depends upon the goals of the soil testing. The examples below serve as guidelines. Please contact Innov-X (1-866-4 Innov-X or 866-446-6689) to discuss your specific testing requirements.

Example 1: Initial site investigation to provide detailed contamination data with efficient use of laboratory analysis costs.

Problem: Site needs to be assessed for metals contamination. Little information is available about what metals are present, likely contamination levels or geographic profile of contamination.

The goal of testing is to determine what metals are present at what levels, both in area and in depth into soil. Additionally, testing will locate possible contamination plumes and/or possible sources of contamination.

Recommended Testing Plan: This example uses predominately in-situ testing. The analyst will perform in-situ testing, and gather samples into plastic bags for XRF analysis. A testing grid should be established in two or three dimensions, every several feet. XRF tests can be taken at each location or bagged samples can be collected from each location for later analysis. The in-situ data for each element analyzed may be plotted in a 2-dimensional grid (X, Y coordinates versus elemental concentration) to profile a site. These concentration profiles are ideal for showing contamination patterns, boundaries and plumes. Combining this data with historical use data from the site often allows the operator to deduce sources of contamination. Obtaining this level of geographic data with purely laboratory analysis would produce excessive analytical costs.

Prepared sample analysis should also be done to confirm the regions where in-situ data indicates low or non-detected levels of metal contaminant. There is little need to prepare areas where in-situ testing indicates high concentration levels. Innov-X recommends the same procedure as EPA Method 6200. For locations where in-situ tested indicate low or non-detected concentrations, calculate the total number of in-situ tests, collect 5% of this number of tests from the various locations, and prepare these samples according to Appendix 1. Use these prepared samples to confirm the findings of the in-situ testing. Send a subset of these prepared samples to a laboratory for confirmatory results.

Cost Justification. To adequately characterize a site may require 100-200 samples/acre to be sure the contaminated areas are firmly established. This work may be done with in-situ testing to generate laboratory savings of $5,000 - $10,000/acre depending upon the number of elements being analyzed. The cost reduction in off-site analysis often justifies the price of the XRF.

Example 2: Monitor remediation efforts and assure site meets clearance levels before contractors leave the site.

Goal: Minimize remediation costs by only treating contaminated soil, and obtain immediate verification that various site locations meet clearance objectives.

Recommended Testing Plan: This type of project uses a lot of both in-situ and prepared sample testing. Use in-situ testing to thoroughly delineate contamination regions in both area and depth. To determine depth profiles, test surface soil, remove at least 1-2 inches, and retest. Repeat this step as necessary to profile contamination depth to guide remediation activities. (XRF is a surface technique and only analysis the first few mm of soil sample). As part of clearance, collect several samples from "cleared" area. Prepare samples according to Appendix 1 and test with portable XRF.

If XRF indicates that concentration levels are in excess of clearance requirements, then continue remediation efforts.

If XRF indicates that concentration levels are below clearance requirements, then discontinue remediation efforts, and send a subset of the samples to an analytical laboratory to confirm results. Most operators safely assume that the cleanup requirements have been met for the elements in question, but await final analysis from the laboratory.

If XRF lists concentration levels as non-detected, but the detection level reported exceeds clearance requirements, send samples to a laboratory for final results.

Cost Justification: In-situ results are used to guide remediation efforts, in order to obtain maximum efficiency. Efficiency is produced because contamination boundaries are firmly established, thus avoiding remediation efforts with "clean" soil. Prepared sample testing is used to assure that clearance requirements are met on-site in near real-time (pending laboratory confirmation). Costs savings are generated by avoiding clearance failures. The contractors can leave the site earlier and will not be called back to the site for additional cleanup.

Important Note: Never clear a site based solely on in-situ testing. Always use well-prepared samples to make a clearance decision.

Example 3: Minimize volume of hazardous waste for treatment or disposal.

Goal: For some cleanup projects, the cost of soil disposal in a hazardous waste landfill is much greater than disposal in a standard landfill. Testing soil samples with XRF may minimize the amount of "clean" soil that is inadvertently shipped to a hazardous-waste landfill.

Recommended Testing Plan: This example is almost entirely prepared sample testing. Representative samples are removed from the soil being hauled to landfill. Obtaining an accurate analysis of the samples is crucial for making a hazardous versus non-hazardous determination. For this reason, prepared sample testing is strongly recommended.

Important Note: These types of samples are subject to TCLP procedures for the landfill determination. In general, 20 times the XRF result should be less than the allowable limit for the metal in question. Please contact Innov-X Systems for more details on testing samples versus TCLP regulatory requirements.

Section 3: Quality Assurance.

Quality assurance is detailed for both the proper use of the analyzer (which is also provided in Method 6200) and for verifying the data quality of in-situ testing. All operators should perform the QC procedure, regardless of their data quality objectives. Method 6200 has strict requirements about quality assurance. Additionally, Innov-X recommends that operators verify the data quality of in-situ test results, if they are using in-situ data to guide their reporting or remediation decisions. Procedures are listed below:

3.1: Proper verification of instrument operation

These procedures are taken from EPA Method 6200 and updated to be specific to the Innov-X analyzer. Quality assurance here consists of testing known standards to verify calibration, as well as testing blank standards to determine limits of detection and to check for sample cross-contamination or instrument contamination. EPA Method 6200 provides a detailed procedure, which is provided here in abbreviated form.

Components of instrument QC:

1. An energy calibration check sample at least twice daily
2. An instrument blank for every 20 environmental samples
3. A method blank for every 20 prepared samples
4. A calibration verification check sample for every 20 samples
5. A precision sample at least one per day.
6. A confirmatory sample for every 10 environmental samples

Energy Calibration Check: The Innov-X analyzer performs this automatically; this is the purpose of the standardization check when the analyzer is started. The software does not allow the analyzer to be used if the standardization is not completed.

Instrument Blank: The operator should use the SiO_2 (silicon dioxide) blank provided with the analyzer. The purpose of this test is to verify there is no contamination on the analyzer window or other component that is "seen" by the x-rays. Method 6200 recommends an instrument blank at least once per day, preferably every 20 samples. For either in-situ or prepared-sample testing, the operator should just test the SiO_2 blank to be sure there are no reported contaminant metals.

Method Blank: The purpose of the method blank is to verify that cross-contamination is not introduced into samples during the sample preparation process. Method 6200 recommends following the sample preparation procedures with clean SiO_2 once very 20 prepared samples. This QC step is not required if the operator is not preparing samples.

Calibration Verification: Innov-X provides NIST standard reference samples for calibration check by operator. The operator should perform a 2-minute test on a NIST standard. The difference between the XRF result for an element and the value of the standard should be 20% or less. Calibration Verification should be performed upon instrument startup and periodically during testing. Note: Innov-X recommends a calibration check every 4 hours. EPA Method 6200 recommends a calibration check every 20 samples NIST reference standards are generally applicable for Pb, As, Cr, Cu, Zn. Innov-X provides additional reference standards for other RCRA or Priority Pollutant metals including Cd, Se, Ag, Hg, Ag, Ba, Sn, Sb, and Ni.

Precision Verification: Quoting from EPA "A minimum of one precision sample should be run per day by conducting from 7 to 10 replicate measurements of the sample. The precision is assessed by calculating a relative standard deviation (RSD) of the replicate measurements for the analyte. The RSD values should be less than 20 percent for most analytes, except chromium, for which the value should be less than 30 percent.

Confirmatory Sample: It is recommended that one confirmatory sample is run for every 10 samples collected. According to EPA Method 6200: "Confirmatory samples are collected from the same sample material that is analyzed on site, but are sent to an off-site laboratory for formal analysis. The purpose of a confirmatory sample is to judge the accuracy of the data obtained by analysis on site and to allow corrections, if necessary."

Important Notes about confirmatory samples:

Innov-X always recommends that customers compare prepared-sample results to laboratory results. To do this, collect and prepare a sample following the protocols of Appendix 1. Take a subsample and submit to the laboratory for analysis. The single largest error in XRF analysis is lack of sample preparation. For the best comparison, always use prepared samples.

3.2: Determining data quality of in-situ testing:

For operators relying extensively on in-situ testing, it is important to determine the data quality of this testing at a given site. *This protocol is not intended for every sample, but rather for a small percentage of samples considered representative of the site.* If the operator can demonstrate that quantitative data is achieved with little or no sample preparation, then the site characterization will be completed much more quickly but correctly.

For example, an operator may be able to demonstrate that the XRF result changes considerably when samples are passed through a 2 mm sieve, but that XRF results do NOT change appreciably upon finer sieving. In this case the operator can conclude that good XRF data is achievable with only 2 mm sieving. Sieving only to this level requires far less time than a more robust sample preparation. A protocol to determine the appropriate level of sample preparation is the following:

1. Delineate a region of soil approximately 4" x 4".
2. Perform several in-situ tests in this area, or collect the top (approximately) quarter inch of soil from this region, bag the soil, test through the bag. In either case, average the results.
3. If you did not bag the in-situ test sample, collect the top (approximately) quarter inch of soil from this region and sieve through the 2 mm sieve provided. Otherwise sieve the bagged sample used for the in-situ test. Thoroughly mix the sieved sample, and place some of the sieved material into an XRF cup, and perform a test of this sample.
4. If the results of this prepared sample differ less than 20% with the average in-situ result, this indicates the soil in this region is reasonably homogeneous. The data quality in this case is probably at the semi-quantitative level, rather than just screening data.
5. If the results differ by more than 20%, this indicates the soil is not very homogeneous, and there are serious particle size effects affecting your in-situ measurements.
6. In this case, sieve the sample through the 250 ~m sieve. Mix this sample and place a sub-sample into an XRF cup for testing. If this result differs from the previous by less than 20% then this indicates that at a minimum the 2mm sieving is necessary to achieve higher data quality.

7. If this result differs by more than 20% from the sample sieved through 2 mm, then particle size effects are still affecting the XRF result. In this case samples should be sieved through 125 μm to assure data quality at the quantitative level.

Section 4: Calibration for Innov-X Portable XRF

The Innov-X analyzer may run three different calibration methods, described below. In nearly all cases, customers use the Compton Normalization method. This method (recognized in EPA 6200) offers speed, ease of use, and generally good accuracy for concentration ranges from the ppm level up to 2-3% concentrations. As most field-testing is seeking to remediate or locate environmental contaminants, the upper limit of the calibration (2-3%) is generally not a limitation. If customers do require a calibration up to 100% concentration (i.e. a pure element) then Innov-X recommends they also include the Fundamental Parameters (FP) software module with the analyzer. The FP module may be added at time of purchase or as an upgrade at any later date.

Note: In general customers do not need to calibrate the Innov-X analyzer for soil testing. The analyzer is delivered with a factory calibration, generally based upon the Compton Normalization (CN) method. The CN method has been proven over the past several years to provide a robust calibration generally independent of site-specific soil matrix chemistry. The operator may calibrate the Innov-X system if desired, but calibration is not required to use the analyzer effectively. All customers should follow the QC procedure described in Section 3, which includes a check of the calibration.

The final model is the empirical calibration. In this case, customers run standards to generate calibration curves for various elements in specific soil matrices. Provided the sample is well-prepared, the empirical method generally yields the most accurate result. In our experience, the accuracy gains going from Compton Normalization to Empirical Mode are small and not worth the extra effort in setting up calibration curves. (The greatest source of error for in-field XRF analysis of soil is lack of adequate sample preparation, thus there is little gained in developing a sophisticated empirical calibration if the operator does to grind and homogenize the all measured samples). The empirical calibration module is an optional software package, available for an upgrade fee at the time of purchase, or as an upgrade at any later date.

Calibration Requirements:

The concentration of an element in a soil sample is well-described by the formula:

$$w_i = \frac{k_i}{M(Z,i)} I_i$$

k_i = calibration constant for element "i"

ω_i = concentration of element "i" – the quantity being measured.

I_i = measured x-ray intensity from element "i"

M(Z,I) = Soil matrix value

The factory calibration determines the value of the calibration constants k_i for each element, and a typical value M(Z,I). The calibration method – either CN, fundamental parameters, or empirical – performs the necessary corrections to the value M(Z,I) that are important for the site-specific soil chemistry. The XRF analyzer uses the measured intensity of each element's fluorescence from the sample, and the calibration data, to produce elemental concentrations.

Compton Normalization:

The Compton Normalization method calibration consists of the analysis of a single, well-characterized standard, such as an SRM or SSCS. The standard data are normalized to the Compton peak. The Compton peak is produced from incoherent backscattering of X-ray radiation from the excitation source and is present in the spectrum of every sample. The matrix affects the way in which source radiation is scattered off the samples. This scatter is directly related to the intensity of the Compton peak. For that reason, normalizing to the Compton peak can reduce problems with matrix effects that vary among samples. Compton normalization is similar to the use of internal standards in analysis for organic analytes.

Fundamental Parameters Calibration:

The fundamental parameters (FP) calibration is a "standardless" calibration. Rather than establishing a unit's calibration curve by measuring its response to standards that contain analytes of known concentrations, FP calibration relies on the known physics of the spectrometer's response to pure elements to set the calibration. Built-in mathematical algorithms are used to adjust the calibration for analysis of soil samples and to compensate for the effects of the soil matrix. The FP calibration is performed by the manufacturer, but the analyst can adjust the calibration curves (slope and y-intercept) on the bases of results of analyses of check samples, such as SRMs which are analyzed in the field.

Empirical Calibration:

The empirical calibration method requires that a number of site-specific calibration standards (SSCS) are used to establish calibration parameters. The instrument response to known analytes is measured and used to create calibration curves. Empirical calibration is effective because the samples used closely match the sample matrix. SSCSs are well-prepared samples collected from the site of interest in which the concentrations of analytes have been determined by inductively coupled plasma (ICP), atomic absorption (AA), or other methods approved by the US Environmental Protection Agency (EPA). The standards should contain all the analytes of interest and interfering analytes. Manufacturers recommend that 10 to 20 calibration samples be used to generate a calibration curve. The empirical method is the least desirable calibration method as it requires that new standards and curves are generated for each site that is analyzed.

Section 5: Effects of Moisture on XRF Results:

Sample moisture has two effects on XRF results:

- It alters the soil chemistry, since water is another chemical compound that comprises the soil matrix.
- Moisture impedes the ability to properly prepare samples.

- Laboratory results are provided on a "dry weight" basis.

Effect on Soil Chemistry:

While the presence of significant moisture does impact the soil chemistry, modern XRF analyzers all perform automatic corrections for variations in soil chemistry from site to site. Indeed, such variations are expected, and that is the reason analyzers use Compton Normalization or fundamental parameters, in order to correct for moisture content changes as well as other differences in soil geochemistry.

EPA Method 6200 states "Moisture content above 20 percent may cause problems, since moisture alters the soil matrix for which the FPXRF has been calibrated." However, the Compton Normalization or fundamental parameters methods are implemented in order to automatically correct results for changes to the soil matrix. Thus, we believe that soil moisture is not a significant effect on accuracy due to effects of soil matrix, except for the "dilution" effect that can cause discrepancies with laboratory results which is described below.

Sample preparation issues:

The inability to adequately prepare a wet sample is, we believe, the single biggest contributor to errors when testing wet samples. It is very difficult to grind or sieve a wet sample. The highest quality XRF results are generally obtained from prepared samples. If the operator is unwilling to dry the sample to prepare it, comparisons to the laboratory may yield poorer correlation since the samples are not homogeneous.

Laboratory Tests on Dry-Weigh Basis:

Laboratories always dry samples prior to analysis. They report percent weight content based upon a dry sample basis. Portable XRF may often be used to analyze wet samples in the field, and results are thus reported that include the moisture content. Thus, with all other factors the same, the laboratory will report results higher than portable XRF. The results will be higher by the amount of moisture content in the sample. For example laboratory results will be 10% higher compared to XRF results, if the sample contained 10% by weight water when it was tested with XRF. Recall, this applies to samples where other possible sources of error are the same or negligible.

Section 6: Comparing XRF Results to Laboratory Results:

Innov-X strongly recommends that operators compare prepared sample results to laboratory results. This is because prepared-sample results yield the best possible accuracy with portable XRF. Moreover, the most common source of error is due to non-uniform samples. The XRF technique, nor can any analytical technique, properly account for non-uniform sample types.

To perform a comparison between XRF results and laboratory:

1. Collect a sample and prepare it according to the sample preparation guide in Appendix 1.

2. Take a sub-sample (5-10 grams) of the fully-prepared sample, place it into an XRF cup and perform at least a one-minute test on that sample.

3. Send the same sample to the laboratory for wet chemistry analysis.

4. Require the laboratory to use a total-digestion method. If the laboratory does not use a total digestion method, they may not extract all of the elemental metal from the sample. In this case, the lab result will be lower than the XRF result. Incomplete sample digestion is one of the most commons sources of laboratory error, thus it is very important to request a total digestion method.

Example of Error: The operator collects a bag of sample, performs XRF analysis on one part of the bag, and sends the bag, or part of the bag of sample to a laboratory for analysis. The laboratory reports a very different value than the operator obtained with the XRF.

Problem: Since the sample is very non-homogeneous, the operator did not obtain a result that was representative of the entire bag of sample. The lab analyzed a different part of the sample and obtained a very different result due to the non-uniformity of the sample. The solution to this problem is, at a minimum, to test several locations in the bag of sample and report the average value. Also note the differences between the tests, as this is indicative of the non-uniformity of the sample. Operator should send entire bag of sample to the lab, and instruct lab to prepare the sample before removing sub-sample for lab analysis.

Best Practice: The operator should homogenize and prepare the entire bag of sample, and then collect a sub sample for XRF testing. After testing, the same sample should be sent to the lab.

Section 7: Common Interferences:

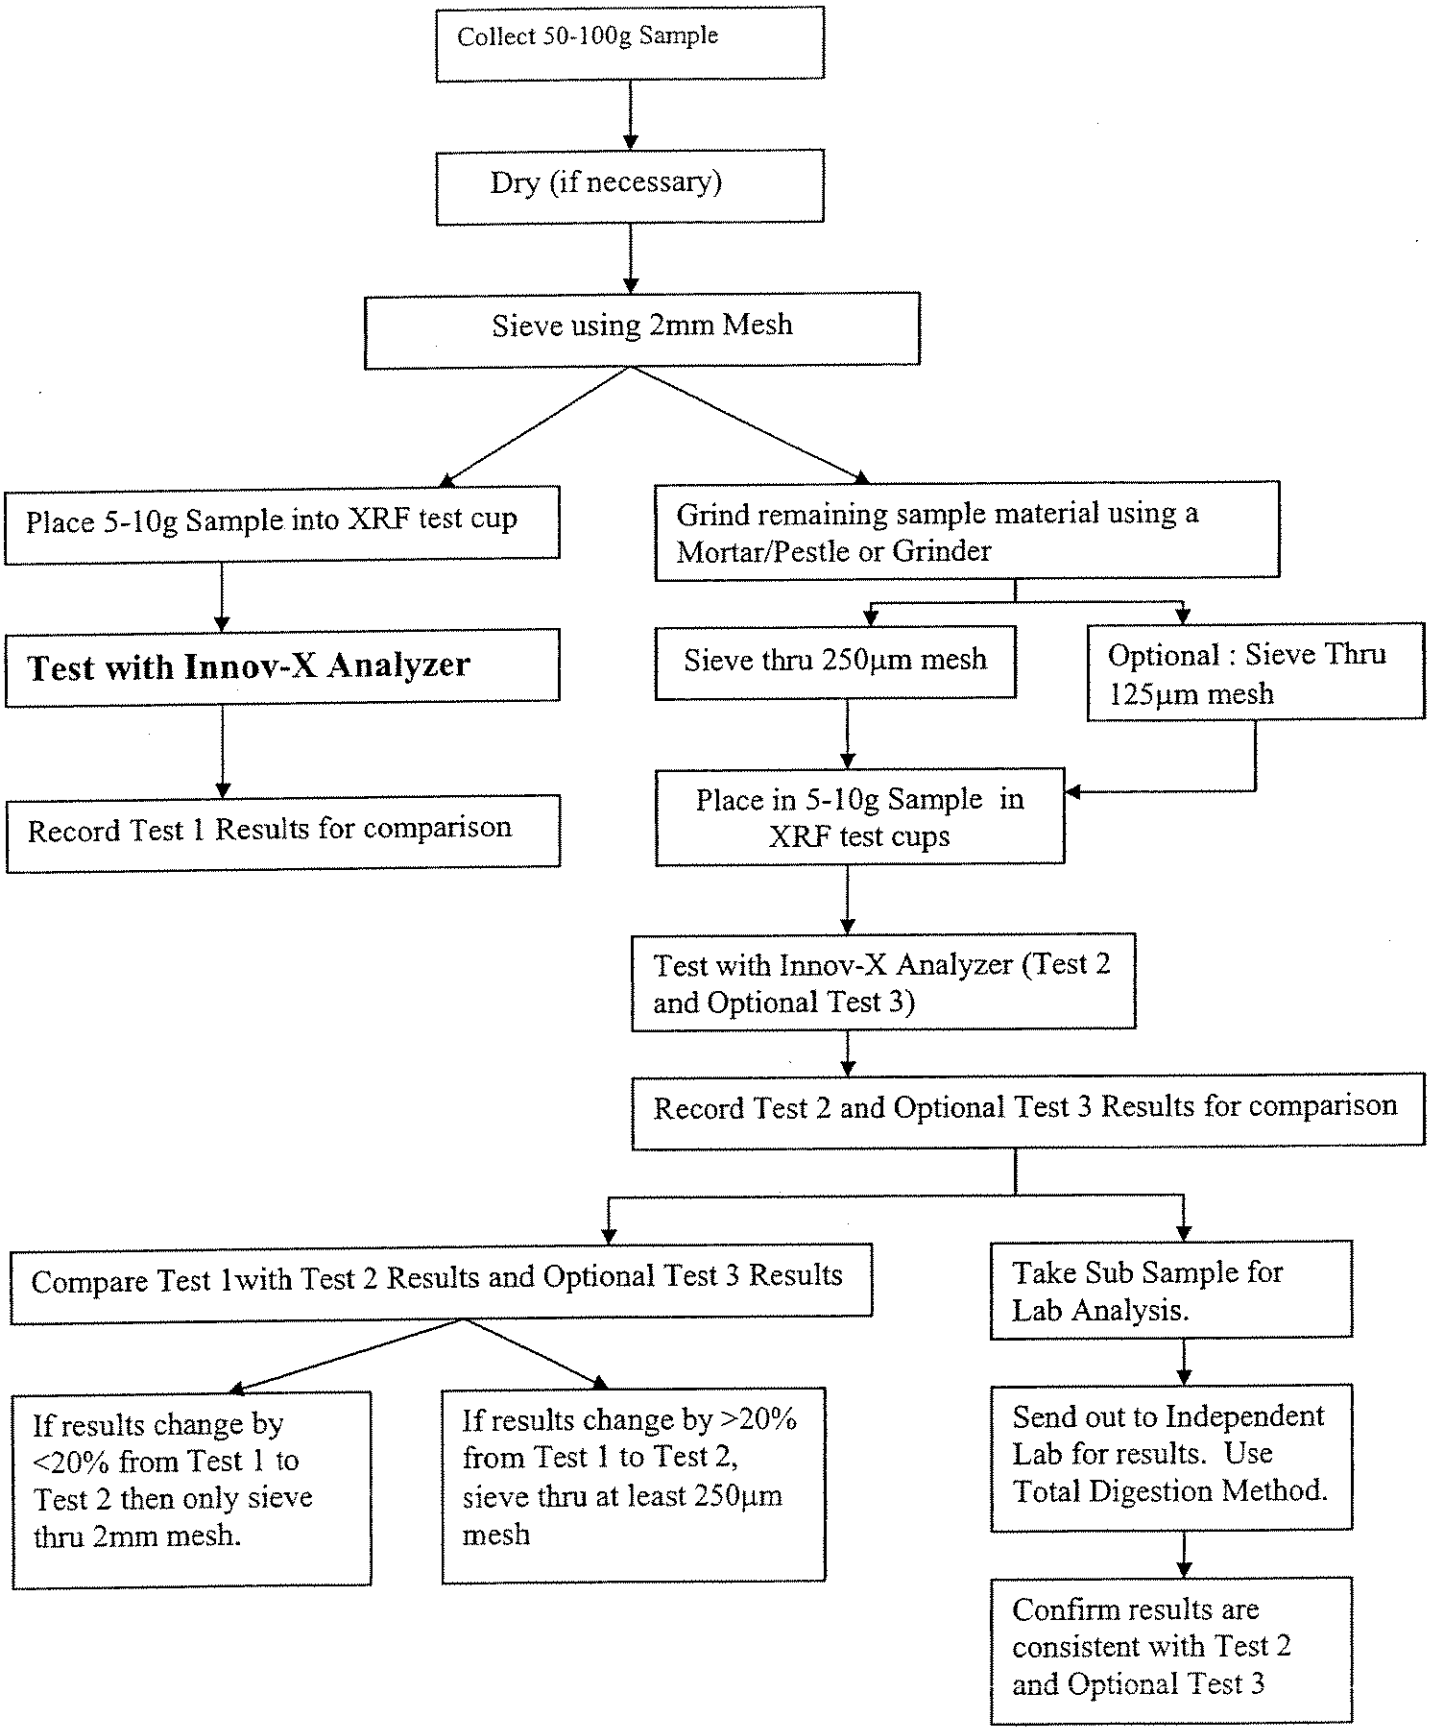
An interference occurs when the spectral peak from one element overlaps either partially or completely with the spectral peak of another. If the XRF is calibrated for both elements (CASE 1) i.e. the one causing the interference and the one being interfered with, it is generally capable of correctly handling the interference. In this case, the element being interfered with may be measured with a poorer detection limit or poorer precision, but the analytical results should still be acceptable for field-portable XRF. If the XRF is not calibrated for the element causing the interference (CASE 2), then the XRF may report the presence of elements not in the sample, or greatly elevated concentrations of elements in or not in the sample.

Example CASE 1: Lead and arsenic. Most XRFs are calibrated for lead and arsenic. Lead interferes with arsenic (not vice-versa though). The net effect is a worsened detection limit for arsenic, and poorer precision. The XRF handles the correction automatically, but the precision is affected. The loss of precision is also reported by the XRF. (Please refer to Innov-X Applications Sheet: *In-field Analysis of Lead and Arsenic in Soil Using Portable XRF* for more detail).

Example CASE 2: Bromine in the sample, but XRF is not calibrated for bromine. Bromine, as a fire retardant, is being seen more and more in soil and other sample types. For this reason, Innov-X analyzers include Br in the calibration data. If Br is not calibrated, but is present in the sample, the analyzer will report highly elevated levels of Pb, Hg and As. The levels will depend upon the concentration of Br in the sample.

Interferences between elements can be broadly categorized into a) Z, Z-1, Z+1 interferences, and b) K/L interferences. Interference type "a" occurs when high levels of an element of atomic number Z are present. This can cause elevated levels of elements with atomic number Z-1 or Z+1. Generally, portable XRFs have good correction methods, so this interference only causes problems with very high levels of the element in question. Example: High concentrations of Fe (Z=26) in excess of 10% may cause elevated levels of Mn or Co (Z=25 or Z=27 respectively).

The type "b" interference occurs when the L-shell line of one element overlaps with the K-shell spectral line of another element. The most common example is the lead/arsenic interference where the L-alpha line of lead is in nearly the exact same location as the K-alpha line of arsenic.



Collect 50-100g Sample
Dry (if necessary)
Sieve using 2mm Mesh
Place 5-10g Sample into XRF test cup
Test with Innov-X Analyzer
Record Test 1 Results for comparison
Grind remaining sample material using a Mortar/Pestle or Grinder
Sieve thru 250µm mesh
Optional : Sieve Thru 125µm mesh
Place in 5-10g Sample in XRF test cups
Test with Innov-X Analyzer (Test 2 and Optional Test 3)
Record Test 2 and Optional Test 3 Results for comparison
Compare Test 1with Test 2 Results and Optional Test 3 Results
If results change by <20% from Test 1 to Test 2 then only sieve thru 2mm mesh.
If results change by >20% from Test 1 to Test 2, sieve thru at least 250µm mesh
Take Sub Sample for Lab Analysis.
Send out to Independent Lab for results. Use Total Digestion Method.
Confirm results are consistent with Test 2 and Optional Test 3

Appendix 3: Guide to Product Registration

Generally, the Innov-X portable XRF system must be registered in the state of usage. Registration requirements are somewhat state dependent, but there are many similarities. You may contact Innov-X at 866-4-Innov-X (781-938-5005) to receive specific registration information. Innov-X also maintains sample registrations for every state that we can forward to you.

Common Registration Features:

Most states require the following for registering an x-ray emitting device that does NOT use radioactive sources:

1. Registration within 30 days of receipt of the analyzer.
2. Annual fee ranging from $25 to $100, depending upon the state.
3. Basic registration form with main information described below.

Common information required on Registration Form, and responses:

Company name, address, phone/fax numbers.

Name of responsible person:	Generally the person designated as the Radiation Safety Officer (RSO).
Name of the manufacturer:	Innov-X Systems, Inc., Woburn, MA
Model of Analyzer:	XT-220 or XT-260.
Tube Operating Parameters:	35 kV, 20 uA current.
Type of Analysis:	Choose Analytical or Industrial
	(as opposed to radiography, medical, dental, veterinarian, etc.)
Utilization Mode:	Portable or Mobile assuming you will carry system to different locations.
	Fixed or stationary ONLY if you will always use the analyzer in the docking station

Innov-X Analyzer Limited Warranty

General Terms

EXCEPT AS EXPRESSLY SET FORTH IN THIS LIMITED WARRANTY, INNOV-X SYSTEMS, INC. (INNOV-X) MAKES NO OTHER WARRANTIES OR CONDITIONS, EXPRESSED OR IMPLIED, INCLUDING ANY IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. INNOV-X EXPRESSLY DISCLAIMS ALL WARRANTIES AND CONDITIONS NOT STATED IN THIS LIMITED WARRANTY. ANY IMPLIED WARRANTIES THAT MAY BE IMPOSED BY LAW ARE LIMITED IN DURATION TO THE LIMITED WARRANTY PERIOD.

This Limited Warranty applies to Innov-X analyzers sold or leased from Innov-X its affiliates, authorized resellers, or country distributors (collectively referred to in this Limited Warranty as ("Innov-X")).

Innov-X warrants that the analyzer and all its internal components that you have purchased are free from defects in materials or workmanship under normal use during the Limited Warranty Period. The Limited Warranty Period starts on the date of shipment by Innov-X. You may be required to provide proof of purchase or lease as a condition of receiving warranty service. You are entitled to warranty service according to the terms and conditions of this document if a repair to your Innov-X analyzer is required within the Limited Warranty Period.

During the Limited Warranty Period, Innov-X will repair or replace the defective component parts. All component parts removed under this Limited Warranty become the property of Innov-X. In the unlikely event that your Innov-X analyzer has a recurring failure, Innov-X, at its discretion, may elect to provide you with a replacement unit of Innov-X's choosing that is at least equivalent to your Innov-X analyzer. This is your exclusive remedy for defective products. The repaired or replacement analyzer is warranted for the remainder of the limited Warranty Period.

YOU SHOULD MAKE PERIODIC BACKUP COPIES OF THE DATA STORED ON YOUR ANALYZER AS A PRECAUTION AGAINST POSSIBLE FAILURES, ALTERATION, OR LOSS OF THE DATA. BEFORE RETURNING ANY UNIT FOR SERVICE, BE SURE TO BACK UP DATA AND REMOVE ANY CONFIDENTIAL, PROPRIETARY, OR PERSONAL INFORMATION. INNOV-X IS NOT RESPONSIBLE FOR DAMAGE TO OR LOSS OF ANY PROGRAMS, OR DATA. INNOV-X IS NOT RESPONSIBLE FOR THE RESTORATION OR REINSTALLATION OF ANY PROGRAMS OR DATA OTHER THAN SOFTWARE INSTALLED BY INNOV-X WHEN THE ANALYZER IS MANUFACTURED.

Innov-X does not warrant that the operation of this analyzer will be uninterrupted or error-free. Innov-X is not responsible for damage that occurs as a result of your failure to follow the instructions that came with the Innov-X analyzer.

This Limited Warranty does not apply to expendable parts. This Limited Warranty does not extend to any analyzer from which the serial number has been removed or that has been damaged or rendered defective (A) as a result of accident, misuse, abuse, or other external causes; (b) by operation outside the usage parameters stated in user documentation that shipped with the product; (c) by modification or service by anyone other than (i) Innov-X, or(ii) a Innov-X authorized service provider, (d) installation of software not approved by Innov-X.

These terms and conditions constitute the complete and exclusive warranty agreement between you and Innov-X regarding the Innov-X analyzer you have purchased or leased. These terms and conditions supersede any prior agreements or representations --- including representations made in Innov-X sales literature or advice given to you by Innov-X or any agent or employee of Innov-X --- that may have been made in connection with your purchase or lease of the Innov-X analyzer. No change to the conditions of this Limited Warranty is valid unless it is made in writing and signed by an authorized representative of Innov-X.

Limitation of Liability

IF YOUR INNOV-X ANALYZER FAILS TO WORK AS WARRANTED ABOVE, YOUR SOLE AND EXCLUSIVE REMEDY SHALL BE REPAIR OR REPLACEMENT. INNOV-X'S MAXIMUM LIABILITY UNDER THIS LIMITED WARRANTY IS EXPRESSLY LIMITED TO THE LESSER OF THE PRICE YOU HAVE PAID FOR THE ANALYZER OR THE COST OF REPAIR OR REPLACEMENT OF ANY COMPONENTS THAT MALFUNCTION IN CONDITION OF NORMAL USE.

INNOV-X IS NOT LIABLE FOR ANY DAMAGE CAUSED BY THE PRODUCT OR THE FAILURE OF THE PRODUCT TO PERFORM INCLUDING ANY LOST PROFITS OR SAVINGS OR SPECIAL, INCIDENTAL, OR CONSEQUENTIAL DAMAGES. INNOV-X IS NOT LIABLE FOR ANY CLAIM MADE BY A THIRD PARTY OR MADE BY YOU FOR A THIRD PARTY.

THIS LIMITATION OF LIABILITY APPLIES WHETHER DAMAGE ARE SOUGHT, OR A CLAIM MADE, UNDER THIS LIMITED WARRATNY OR AS A TORT CLAIM (INCLUDING NEGLIGENCE AND STRICT PRODUCT LIABILITY), A CONTRACT CLAIM, OR ANY OTHER CLAIM. THIS LIMITATION OF LIABILITY CANNOT BE WAIVED OR AMENDED BY ANY PERSON. THIS LIMITATION OF LIABILITY WILL BE EFFECTIVE EVEN IF YOU HAVE ADVISED INNOV-X OR AN AUTHORIZED REPRESENTATIVE OF INNOV-X OF THE POSSIBILITY OF ANY SUCH DAMAGES.

Software

This Limited Warranty does not warrant software products. The Innov-X software installed on your analyzer is covered by the Innov-X Software License.

Warranty Period

The warranty period for a Model XT-245 or Model XT-260 Innov-X analyzer is two years or four thousand hours of use, whichever occurs first. The warranty for all other analyzers is one year or two thousands hours of use whichever occurs first. This warranty does not extend to expendable parts. Extended warranties are available from Innov-X.

Warranty Returns

A Return Material Authorization (RMA) Number must be obtained from the INNOV-X Service Department before any items can be shipped to the factory. Returned goods will not be accepted without an RMA Number. Customer will bear all shipping charges for warranty repairs. All goods returned to the factory for warranty repair should be properly packed to avoid damage and clearly marked with the RMA Number.

Warranty Repairs

Warranty repairs will be done either at the customer's site or at the INNOV-X plant, at our option. All service rendered by INNOV-X will be performed in a professional manner by qualified personnel.

Contacting Innov-X

Be sure to have the following information available before you call Innov-X:

- Analyzer serial number, model name, and model number
- Applicable error messages
- Description of problem
- Detailed questions

Methods of Contact

- Phone: 781-635-5005
- Fax 781-938-0128
- Email service@Innov-Xsys.com
- Mail & Shipping Address: Innov-X Systems, Inc. 10 Gill Street, Suite Q. Woburn MA 01801

APPENDIX F

ASTM D 2488 STANDARD METHOD FOR CLASSIFICATION OF SOILS IN THE FIELD

Designation: D 2488 – 93

AMERICAN SOCIETY FOR TESTING AND MATERIALS
100 Barr Harbor Dr., West Conshohocken, PA 19428
Reprinted from the Annual Book of ASTM Standards. Copyright ASTM
If not listed in the current combined index, will appear in the next edition

Standard Practice for Description and Identification of Soils (Visual-Manual Procedure)[1]

This standard is issued under the fixed designation D 2488; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 This practice covers procedures for the description of soils for engineering purposes.

1.2 This practice also describes a procedure for identifying soils, at the option of the user, based on the classification system described in Test Method D 2487. The identification is based on visual examination and manual tests. It must be clearly stated in reporting an identification that it is based on visual-manual procedures.

1.2.1 When precise classification of soils for engineering purposes is required, the procedures prescribed in Test Method D 2487 shall be used.

1.2.2 In this practice, the identification portion assigning a group symbol and name is limited to soil particles smaller than 3 in. (75 mm).

1.2.3 The identification portion of this practice is limited to naturally occurring soils (disturbed and undisturbed).

NOTE 1—This practice may be used as a descriptive system applied to such materials as shale, claystone, shells, crushed rock, etc. (See Appendix X2).

1.3 The descriptive information in this practice may be used with other soil classification systems or for materials other than naturally occurring soils.

1.4 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For specific precautionary statements see Section 8.

1.5 The values stated in inch-pound units are to be regarded as the standard.

2. Referenced Documents

2.1 *ASTM Standards:*

D 653 Terminology Relating to Soil, Rock, and Contained Fluids[2]

D 1452 Practice for Soil Investigation and Sampling by Auger Borings[2]

D 1586 Method for Penetration Test and Split-Barrel Sampling of Soils[2]

D 1587 Practice for Thin-Walled Tube Sampling of Soils[2]

D 2113 Practice for Diamond Core Drilling for Site Investigation[2]

D 2487 Classification of Soils for Engineering Purposes (Unified Soil Classification System)[2]

D 4083 Practice for Description of Frozen Soils (Visual-Manual Procedure)[2]

3. Terminology

3.1 *Definitions:*

3.1.1 Except as listed below, all definitions are in accordance with Terminology D 653.

NOTE 2—For particles retained on a 3-in. (75-mm) US standard sieve, the following definitions are suggested:

Cobbles—particles of rock that will pass a 12-in. (300-mm) square opening and be retained on a 3-in. (75-mm) sieve, and

Boulders—particles of rock that will not pass a 12-in. (300-mm) square opening.

3.1.1.2 *clay*—soil passing a No. 200 (75-μm) sieve that can be made to exhibit plasticity (putty-like properties) within a range of water contents, and that exhibits considerable strength when air-dry. For classification, a clay is a fine-grained soil, or the fine-grained portion of a soil, with a plasticity index equal to or greater than 4, and the plot of plasticity index versus liquid limit falls on or above the "A" line (see Fig. 3 of Test Method D 2487).

3.1.1.3 *gravel*—particles of rock that will pass a 3-in. (75-mm) sieve and be retained on a No. 4 (4.75-mm) sieve with the following subdivisions:

coarse—passes a 3-in. (75-mm) sieve and is retained on a ¾-in. (19-mm) sieve.

fine—passes a ¾-in. (19-mm) sieve and is retained on a No. 4 (4.75-mm) sieve.

3.1.1.4 *organic clay*—a clay with sufficient organic content to influence the soil properties. For classification, an organic clay is a soil that would be classified as a clay, except that its liquid limit value after oven drying is less than 75 % of its liquid limit value before oven drying.

3.1.1.5 *organic silt*—a silt with sufficient organic content to influence the soil properties. For classification, an organic silt is a soil that would be classified as a silt except that its liquid limit value after oven drying is less than 75 % of its liquid limit value before oven drying.

3.1.1.6 *peat*—a soil composed primarily of vegetable tissue in various stages of decomposition usually with an organic odor, a dark brown to black color, a spongy consistency, and a texture ranging from fibrous to amorphous.

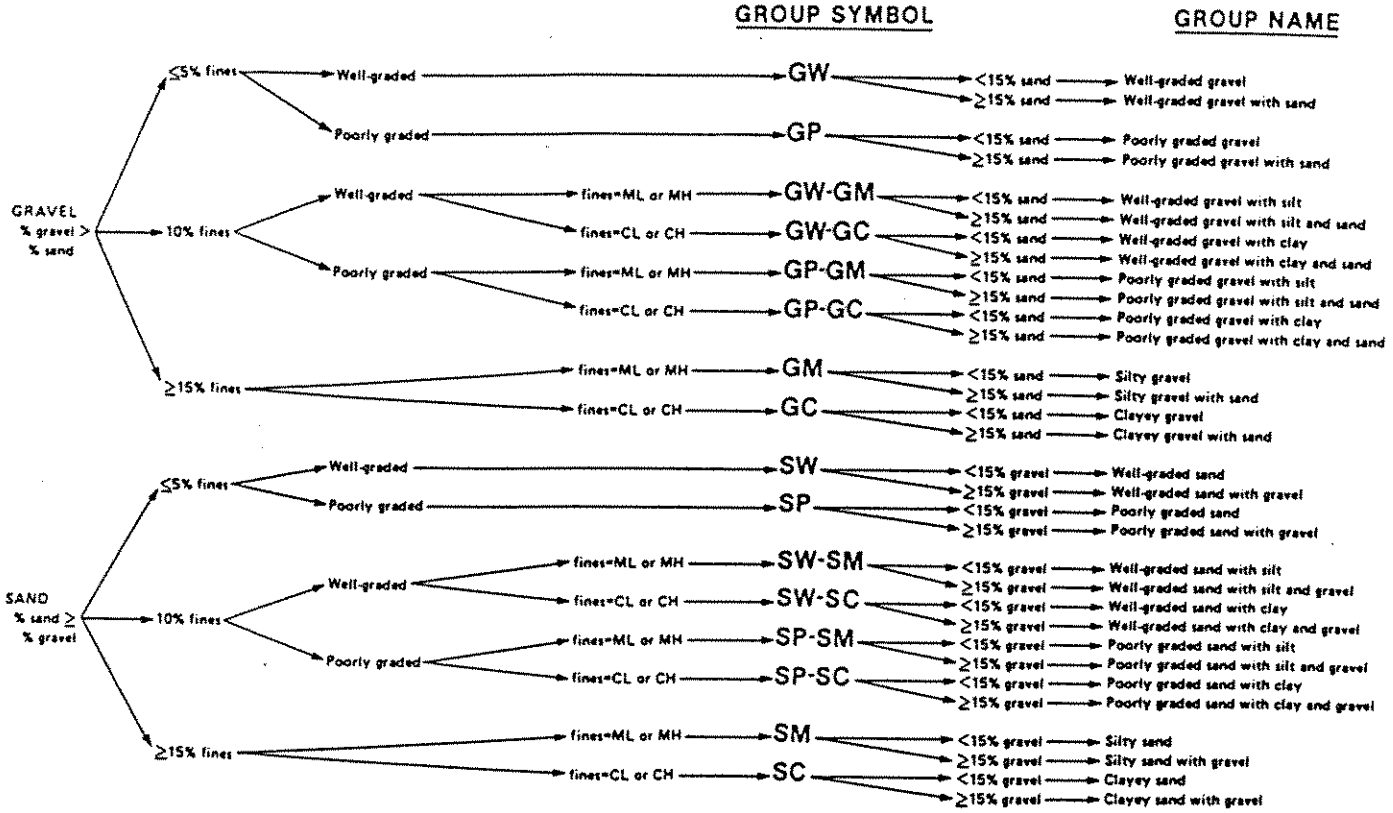
3.1.1.7 *sand*—particles of rock that will pass a No. 4

---

[1] This practice is under the jurisdiction of ASTM Committee D-18 on Soil and Rock and is the direct responsibility of Subcommittee D18.07 on Identification and Classification of Soils.

Current edition approved Sept. 15, 1993. Published November 1993. Originally published as D 2488 – 66 T. Last previous edition D 2488 – 90.

[2] *Annual Book of ASTM Standards*, Vol 04.08.



NOTE—Percentages are based on estimating amounts of fines, sand, and gravel to the nearest 5 %.

FIG. 2 Flow Chart for Identifying Coarse-Grained Soils (less than 50 % fines)

when the liquid limit and plasticity index values plot in the CL-ML area of the plasticity chart.

Borderline Symbol—A borderline symbol is two symbols separated by a slash, for example, CL/CH, GM/SM, CL/ML. A borderline symbol should be used to indicate that the soil has been identified as having properties that do not distinctly place the soil into a specific group (see Appendix X3).

5. Significance and Use

5.1 The descriptive information required in this practice can be used to describe a soil to aid in the evaluation of its significant properties for engineering use.

5.2 The descriptive information required in this practice should be used to supplement the classification of a soil as determined by Test Method D 2487.

5.3 This practice may be used in identifying soils using the classification group symbols and names as prescribed in Test Method D 2487. Since the names and symbols used in this practice to identify the soils are the same as those used in Test Method D 2487, it shall be clearly stated in reports and all other appropriate documents, that the classification symbol and name are based on visual-manual procedures.

5.4 This practice is to be used not only for identification of soils in the field, but also in the office, laboratory, or wherever soil samples are inspected and described.

5.5 This practice has particular value in grouping similar soil samples so that only a minimum number of laboratory tests need be run for positive soil classification.

NOTE 4—The ability to describe and identify soils correctly is learned more readily under the guidance of experienced personnel, but it may also be acquired systematically by comparing numerical laboratory test results for typical soils of each type with their visual and manual characteristics.

5.6 When describing and identifying soil samples from a given boring, test pit, or group of borings or pits, it is not necessary to follow all of the procedures in this practice for every sample. Soils which appear to be similar can be grouped together; one sample completely described and identified with the others referred to as similar based on performing only a few of the descriptive and identification procedures described in this practice.

5.7 This practice may be used in combination with Practice D 4083 when working with frozen soils.

6. Apparatus

6.1 *Required Apparatus:*

6.1.1 *Pocket Knife or Small Spatula.*

6.2 *Useful Auxiliary Apparatus:*

6.2.1 *Small Test Tube and Stopper* (or jar with a lid).

6.2.2 *Small Hand Lens.*

7. Reagents

7.1 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean water from a city water supply or natural source, including non-potable water.

7.2 *Hydrochloric Acid*—A small bottle of dilute hydrochloric acid, HCl, one part HCl (10 *N*) to three parts water (This reagent is optional for use with this practice). See Section 8.

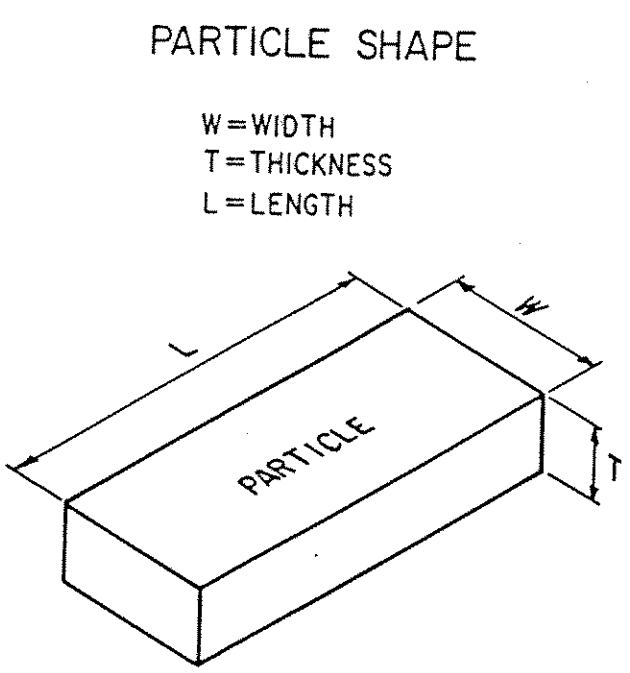


FIG. 4 Criteria for Particle Shape

TABLE 3 Criteria for Describing Moisture Condition

Description	Criteria
Dry	Absence of moisture, dusty, dry to the touch
Moist	Damp but no visible water
Wet	Visible free water, usually soil is below water table

locality it may also be useful in identifying materials of similar geologic origin. If the sample contains layers or patches of varying colors, this shall be noted and all representative colors shall be described. The color shall be described for moist samples. If the color represents a dry condition, this shall be stated in the report.

10.4 *Odor*—Describe the odor if organic or unusual. Soils containing a significant amount of organic material usually have a distinctive odor of decaying vegetation. This is especially apparent in fresh samples, but if the samples are dried, the odor may often be revived by heating a moistened sample. If the odor is unusual (petroleum product, chemical, and the like), it shall be described.

10.5 *Moisture Condition*—Describe the moisture condition as dry, moist, or wet, in accordance with the criteria in Table 3.

10.6 *HCl Reaction*—Describe the reaction with HCl as none, weak, or strong, in accordance with the critera in Table 4. Since calcium carbonate is a common cementing agent, a report of its presence on the basis of the reaction with dilute hydrochloric acid is important.

TABLE 4 Criteria for Describing the Reaction With HCl

Description	Criteria
None	No visible reaction
Weak	Some reaction, with bubbles forming slowly
Strong	Violent reaction, with bubbles forming immediately

TABLE 5 Criteria for Describing Consistency

Description	Criteria
Very soft	Thumb will penetrate soil more than 1 in. (25 mm)
Soft	Thumb will penetrate soil about 1 in. (25 mm)
Firm	Thumb will indent soil about ¼ in. (6 mm)
Hard	Thumb will not indent soil but readily indented with thumbnail
Very hard	Thumbnail will not indent soil

10.7 *Consistency*—For intact fine-grained soil, describe the consistency as very soft, soft, firm, hard, or very hard, in accordance with the criteria in Table 5. This observation is inappropriate for soils with significant amounts of gravel.

10.8 *Cementation*—Describe the cementation of intact coarse-grained soils as weak, moderate, or strong, in accordance with the criteria in Table 6.

10.9 *Structure*—Describe the structure of intact soils in accordance with the criteria in Table 7.

10.10 *Range of Particle Sizes*—For gravel and sand components, describe the range of particle sizes within each component as defined in 3.1.2 and 3.1.6. For example, about 20 % fine to coarse gravel, about 40 % fine to coarse sand.

10.11 *Maximum Particle Size*—Describe the maximum particle size found in the sample in accordance with the following information:

10.11.1 *Sand Size*—If the maximum particle size is a sand size, describe as fine, medium, or coarse as defined in 3.1.6. For example: maximum particle size, medium sand.

10.11.2 *Gravel Size*—If the maximum particle size is a gravel size, describe the maximum particle size as the smallest sieve opening that the particle will pass. For example, maximum particle size, 1½ in. (will pass a 1½-in. square opening but not a ¾-in. square opening).

10.11.3 *Cobble or Boulder Size*—If the maximum particle size is a cobble or boulder size, describe the maximum dimension of the largest particle. For example: maximum dimension, 18 in. (450 mm).

10.12 *Hardness*—Describe the hardness of coarse sand and larger particles as hard, or state what happens when the particles are hit by a hammer, for example, gravel-size particles fracture with considerable hammer blow, some gravel-size particles crumble with hammer blow. "Hard" means particles do not crack, fracture, or crumble under a hammer blow.

10.13 Additional comments shall be noted, such as the presence of roots or root holes, difficulty in drilling or augering hole, caving of trench or hole, or the presence of mica.

10.14 A local or commercial name or a geologic interpre-

TABLE 6 Criteria for Describing Cementation

Description	Criteria
Weak	Crumbles or breaks with handling or little finger pressure
Moderate	Crumbles or breaks with considerable finger pressure
Strong	Will not crumble or break with finger pressure

TABLE 9 Criteria for Describing Dilatancy

Description	Criteria
None	No visible change in the specimen
Slow	Water appears slowly on the surface of the specimen during shaking and does not disappear or disappears slowly upon squeezing
Rapid	Water appears quickly on the surface of the specimen during shaking and disappears quickly upon squeezing

TABLE 10 Criteria for Describing Toughness

Description	Criteria
Low	Only slight pressure is required to roll the thread near the plastic limit. The thread and the lump are weak and soft
Medium	Medium pressure is required to roll the thread to near the plastic limit. The thread and the lump have medium stiffness
High	Considerable pressure is required to roll the thread to near the plastic limit. The thread and the lump have very high stiffness

the surface of the soil. Squeeze the sample by closing the hand or pinching the soil between the fingers, and note the reaction as none, slow, or rapid in accordance with the criteria in Table 9. The reaction is the speed with which water appears while shaking, and disappears while squeezing.

14.4 *Toughness:*

14.4.1 Following the completion of the dilatancy test, the test specimen is shaped into an elongated pat and rolled by hand on a smooth surface or between the palms into a thread about ⅛ in. (3 mm) in diameter. (If the sample is too wet to roll easily, it should be spread into a thin layer and allowed to lose some water by evaporation.) Fold the sample threads and reroll repeatedly until the thread crumbles at a diameter of about ⅛ in. The thread will crumble at a diameter of ⅛ in. when the soil is near the plastic limit. Note the pressure required to roll the thread near the plastic limit. Also, note the strength of the thread. After the thread crumbles, the pieces should be lumped together and kneaded until the lump crumbles. Note the toughness of the material during kneading.

14.4.2 Describe the toughness of the thread and lump as low, medium, or high in accordance with the criteria in Table 10.

14.5 *Plasticity*—On the basis of observations made during the toughness test, describe the plasticity of the material in accordance with the criteria given in Table 11.

14.6 Decide whether the soil is an *inorganic* or an *organic* fine-grained soil (see 14.8). If inorganic, follow the steps given in 14.7.

14.7 *Identification of Inorganic Fine-Grained Soils:*

TABLE 11 Criteria for Describing Plasticity

Description	Criteria
Nonplastic	A ⅛-in. (3-mm) thread cannot be rolled at any water content
Low	The thread can barely be rolled and the lump cannot be formed when drier than the plastic limit
Medium	The thread is easy to roll and not much time is required to reach the plastic limit. The thread cannot be rerolled after reaching the plastic limit. The lump crumbles when drier than the plastic limit
High	It takes considerable time rolling and kneading to reach the plastic limit. The thread can be rerolled several times after reaching the plastic limit. The lump can be formed without crumbling when drier than the plastic limit

14.7.1 Identify the soil as a *lean clay*, CL, if the soil has medium to high dry strength, no or slow dilatancy, and medium toughness and plasticity (see Table 12).

14.7.2 Identify the soil as a *fat clay*, CH, if the soil has high to very high dry strength, no dilatancy, and high toughness and plasticity (see Table 12).

14.7.3 Identify the soil as a *silt*, ML, if the soil has no to low dry strength, slow to rapid dilatancy, and low toughness and plasticity, or is nonplastic (see Table 12).

14.7.4 Identify the soil as an *elastic silt*, MH, if the soil has low to medium dry strength, no to slow dilatancy, and low to medium toughness and plasticity (see Table 12).

NOTE 11—These properties are similar to those for a lean clay. However, the silt will dry quickly on the hand and have a smooth, silky feel when dry. Some soils that would classify as MH in accordance with the criteria in Test Method D 2487 are visually difficult to distinguish from lean clays, CL. It may be necessary to perform laboratory testing for proper identification.

14.8 *Identification of Organic Fine-Grained Soils:*

14.8.1 Identify the soil as an *organic soil*, OL/OH, if the soil contains enough organic particles to influence the soil properties. Organic soils usually have a dark brown to black color and may have an organic odor. Often, organic soils will change color, for example, black to brown, when exposed to the air. Some organic soils will lighten in color significantly when air dried. Organic soils normally will not have a high toughness or plasticity. The thread for the toughness test will be spongy.

NOTE 12—In some cases, through practice and experience, it may be possible to further identify the organic soils as organic silts or organic clays, OL or OH. Correlations between the dilatancy, dry strength, toughness tests, and laboratory tests can be made to identify organic soils in certain deposits of similar materials of known geologic origin.

14.9 If the soil is estimated to have 15 to 25 % sand or gravel, or both, the words "with sand" or "with gravel" (whichever is more predominant) shall be added to the group name. For example: "lean clay with sand, CL" or "silt with gravel, ML" (see Figs. 1a and 1b). If the percentage of sand is equal to the percentage of gravel, use "with sand."

14.10 If the soil is estimated to have 30 % or more sand or gravel, or both, the words "sandy" or "gravelly" shall be added to the group name. Add the word "sandy" if there appears to be more sand than gravel. Add the word "gravelly" if there appears to be more gravel than sand. For example: "sandy lean clay, CL", "gravelly fat clay, CH", or "sandy silt, ML" (see Figs. 1a and 1b). If the percentage of sand is equal to the percent of gravel, use "sandy."

15. Procedure for Identifying Coarse-Grained Soils (Contains less than 50 % fines)

15.1 The soil is a *gravel* if the percentage of gravel is estimated to be more than the percentage of sand.

TABLE 12 Identification of Inorganic Fine-Grained Soils from Manual Tests

Soil Symbol	Dry Strength	Dilatancy	Toughness
ML	None to low	Slow to rapid	Low or thread cannot be formed
CL	Medium to high	None to slow	Medium
MH	Low to medium	None to slow	Low to medium
CH	High to very high	None	High

APPENDIXES

(Nonmandatory Information)

X1. EXAMPLES OF VISUAL SOIL DESCRIPTIONS

X1.1 The following examples show how the information required in 16.1 can be reported. The information that is included in descriptions should be based on individual circumstances and need.

X1.1.1 *Well-Graded Gravel with Sand (GW)*—About 75 % fine to coarse, hard, subangular gravel; about 25 % fine to coarse, hard, subangular sand; trace of fines; maximum size, 75 mm, brown, dry; no reaction with HCl.

X1.1.2 *Silty Sand with Gravel (SM)*—About 60 % predominantly fine sand; about 25 % silty fines with low plasticity, low dry strength, rapid dilatancy, and low toughness; about 15 % fine, hard, subrounded gravel, a few gravel-size particles fractured with hammer blow; maximum size, 25 mm; no reaction with HCl (Note—Field sample size smaller than recommended).

In-Place Conditions—Firm, stratified and contains lenses of silt 1 to 2 in. (25 to 50 mm) thick, moist, brown to gray; in-place density 106 lb/ft^3; in-place moisture 9 %.

X1.1.3 *Organic Soil (OL/OH)*—About 100 % fines with low plasticity, slow dilatancy, low dry strength, and low toughness; wet, dark brown, organic odor; weak reaction with HCl.

X1.1.4 *Silty Sand with Organic Fines (SM)*—About 75 % fine to coarse, hard, subangular reddish sand; about 25 % organic and silty dark brown nonplastic fines with no dry strength and slow dilatancy; wet; maximum size, coarse sand; weak reaction with HCl.

X1.1.5 *Poorly Graded Gravel with Silt, Sand, Cobbles and Boulders (GP-GM)*—About 75 % fine to coarse, hard, subrounded to subangular gravel; about 15 % fine, hard, subrounded to subangular sand; about 10 % silty nonplastic fines; moist, brown; no reaction with HCl; original field sample had about 5 % (by volume) hard, subrounded cobbles and a trace of hard, subrounded boulders, with a maximum dimension of 18 in. (450 mm).

X2. USING THE IDENTIFICATION PROCEDURE AS A DESCRIPTIVE SYSTEM FOR SHALE, CLAYSTONE, SHELLS, SLAG, CRUSHED ROCK, AND THE LIKE

X2.1 The identification procedure may be used as a descriptive system applied to materials that exist in-situ as shale, claystone, sandstone, siltstone, mudstone, etc., but convert to soils after field or laboratory processing (crushing, slaking, and the like).

X2.2 Materials such as shells, crushed rock, slag, and the like, should be identified as such. However, the procedures used in this practice for describing the particle size and plasticity characteristics may be used in the description of the material. If desired, an identification using a group name and symbol according to this practice may be assigned to aid in describing the material.

X2.3 The group symbol(s) and group names should be placed in quotation marks or noted with some type of distinguishing symbol. See examples.

X2.4 Examples of how group names and symbols can be incororated into a descriptive system for materials that are not naturally occurring soils are as follows:

X2.4.1 *Shale Chunks*—Retrieved as 2 to 4-in. (50 to 100-mm) pieces of shale from power auger hole, dry, brown, no reaction with HCl. After slaking in water for 24 h, material identified as "Sandy Lean Clay (CL)"; about 60 % fines with medium plasticity, high dry strength, no dilatancy, and medium toughness; about 35 % fine to medium, hard sand; about 5 % gravel-size pieces of shale.

X2.4.2 *Crushed Sandstone*—Product of commercial crushing operation; "Poorly Graded Sand with Silt (SP-SM)"; about 90 % fine to medium sand; about 10 % nonplastic fines; dry, reddish-brown, strong reaction with HCl.

X2.4.3 *Broken Shells*—About 60 % gravel-size broken shells; about 30 % sand and sand-size shell pieces; about 10 % fines; "Poorly Graded Gravel with Sand (GP)."

X2.4.4 *Crushed Rock*—Processed from gravel and cobbles in Pit No. 7; "Poorly Graded Gravel (GP)"; about 90 % fine, hard, angular gravel-size particles; about 10 % coarse, hard, angular sand-size particles; dry, tan; no reaction with HCl.

X3. SUGGESTED PROCEDURE FOR USING A BORDERLINE SYMBOL FOR SOILS WITH TWO POSSIBLE IDENTIFICATIONS.

X3.1 Since this practice is based on estimates of particle size distribution and plasticity characteristics, it may be difficult to clearly identify the soil as belonging to one category. To indicate that the soil may fall into one of two possible basic groups, a borderline symbol may be used with the two symbols separated by a slash. For example: SC/CL or CL/CH.

X3.1.1 A borderline symbol may be used when the

X6. RATIONALE

Changes in this version from the previous version, D 2488 – 90, include the addition of X5 on Abbreviated Soil Classification Symbols.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

APPENDIX G
LOW FLOW GROUNDWATER SAMPLING PROCEDURES DOCUMENTS

APPENDIX G-1
Ground Water Sampling Procedure Low Stress (Low Flow) Purging and Sampling

Low-Flow Purging and Sampling

A. Method Summary and Application

The purpose of Low-Flow Purging and Sampling (LFPS) is to collect groundwater samples from monitor wells that are representative of ambient groundwater conditions in the aquifer. This is accomplished by setting the intake velocity of the sampling pump to a flow rate that limits drawdown inside the well. LFPS has three primary benefits. First, it minimizes disturbance of sediment in the bottom of the well, thereby producing a sample with low turbidity. Second, LFPS minimizes aeration of the groundwater during sample collection. Third, the amount of groundwater purged from a well is usually reduced as compared to conventional groundwater purging and sampling methods.

Because the method allows collection of groundwater samples with low turbidity, it was originally used for collecting samples for inorganics analysis. The method typically allows the collection of samples for total metals analysis and eliminates the need to filter the samples for dissolved metals analysis. In addition, since the method minimizes aeration of the samples, it can be used to collect samples for analysis of volatile and semi-volatile organic compounds (VOCs and SVOCs), provided that appropriate pumps are used in sample collection, as discussed below.

Advantages of LFPS are:

- Groundwater samples tend to be more representative of actual aquifer conditions with respect to mobile contaminants and turbidity
- It causes minimal disturbance of the formation adjacent to the screened interval
- It is generally less prone to sampling variability compared to other groundwater sampling techniques (e.g., bailers)
- Smaller purge volumes and associated disposal expense
- Increased sample consistency from dedicated systems and reproducibility of data due to reduced operator variability

Disadvantages of LFPS are:

- Misconceptions regarding reduced purging and sampling time
- Sampling from non-dedicated systems requires greater set-up time
- Sampling from dedicated systems requires higher initial capital expenses
- Increased technical complexity
- Increased training needs for sampling personnel
- Attractiveness of advantages may lead to improper and inconsistent application
- Typically not a “first round” sampling option
- Not recommended for wells with long screen intervals unless multiple samples are collected

1. Introduction

The following procedures are specific to LFPS of monitor wells in New Jersey. These procedures were developed in consideration of the USEPA-Region I guidance document dated July 30, 1996

(http://www.epa.gov/region01/measure/well/lowflow8.pdf) and the USEPA-Region II guidance document dated March 16, 1998 (http://www.epa.gov/Region2/desa/hsw/lowflow.txt). In addition, the U.S. Geological Survey's (USGS) Techniques of Water-Resources Investigations, Book 9, National Field Manual for the Collection of Water-Quality Data was consulted (http://water.usgs.gov/owq/FieldManual/). The reader is encouraged to review these guidance documents prior to performing LFPS. The procedures provided in the USEPA and USGS guidance must be followed except where they differ from the information provided below.

2. Low Flow Policy

In the event that a responsible party is conducting a Remedial Investigation without Departmental oversight, submittal of a sampling plan is not required. However, it is highly recommended that the responsible party seek approval for any deviations from this guidance prior to conducting LFPS. In the event that a responsible party decides to use LFPS without submitting a sampling plan and receiving approval, it must be recognized that any deviations from this guidance may result in rejection of the data. In addition, when submitting the results of the LFPS event, the responsible party must include specific details of the LFPS techniques used which demonstrate that they were consistent with the guidance specified below. The responsible party shall also provide adequate rationale justifying any deviations from this guidance whether or not they were previously approved by the Department.

It is also Departmental policy that LFPS is not an acceptable method for any wells with screened or open borehole intervals greater than 5 feet in length **unless:** 1) multiple locations at five-foot intervals along the screen/borehole are sampled, or 2) the data quality objectives (DQOs) warrant sampling a specific zone (e.g., the shallow water table to investigate the potential for vapor intrusion inside a building) or specific zones where sufficient geophysical (e.g., heat-pulse flowmeter, caliper and temperature logs, etc.) and hydrogeological information (e.g., tracer tests) or other evidence (e.g., stained soils or fractures noted on boring logs) that **clearly** identifies the depth(s) at which contaminants are entering the well screen or open borehole.

Once the collection of multiple samples (vertical profiling) in a well has been completed, long-term sampling of the well may require LFPS at fewer depth intervals, or even just one depth interval, depending on the data quality objectives of the sampling and the types of contamination present in the groundwater (e.g., LNAPL, DNAPL, etc).

3. Laboratory Certification (N.J.A.C. 7:18)

N N.J.A.C. 7:18 requires that any environmental laboratory* submitting analytical data to the Department, regardless of quality level, must be certified by the Office of Quality Assurance. This applies to those firms using LFPS instruments associated with the "analyze immediately" category of water quality indicator parameters (WQIPs) including pH, temperature, and dissolved oxygen. Regardless of whether or not the equipment in question is rented or privately owned the requirement for certification can not be ignored. All certification documentation must accompany the instrument into the field and accompany all WQIP data submitted to the Department. (*Environmental laboratory is defined as any laboratory, facility, consulting firm, government or private agency, business entity or other person that the Department has authorized, pursuant to N.J.A.C. 7:18, to perform analysis in

accordance with the procedures of a given analytical method using a particular technique as set forth in a certain methods reference document and to report the results from the analysis of environmental samples in compliance with a Departmental regulatory program).

B. Specific LFPS Considerations

1. Pump Intake Location

When LFPS is performed correctly, the data being collected should be a snapshot of a narrow zone along a length of well screen or fracture in an open borehole. For these reasons, it is important to place the pump intake in the zone of highest contaminant concentration or contaminant flux along the screened/open-hole interval. This is particularly important in wells constructed with more than 5 feet of well screen.

Information to be considered when selecting the pump intake depth should include: 1) evidence of soil/sediment contamination from boring logs; 2) soil/sediment sampling analytical results; 3) vertical profiles of groundwater and soil contamination developed from direct-push sampling and field-screening techniques; and; 4) lithology/stratigraphy, particularly the permeability of the aquifer materials.

Typically, the most permeable zones are selected for the pump intake location since the majority of contaminant mass will be transported through them, particularly as the plume migrates downgradient of the source area. Identification of these zones may be made from borehole geophysical data, (e.g., resistivity, fluid conductance, or natural gamma logging, etc.) and hydraulic conductivity data or grain-size analyses. The use of a series of passive-diffusion-bag samplers in a well may also help to identify the zone of highest VOC contamination. The physical/chemical behavior of the contaminants of concern should be considered when determining the pump intake depth . For example, gasoline-related contaminants may be present near the water table while chlorinated VOCs may be present deeper in the aquifer. If a well is contaminated by both types of contaminants, both may need to be sampled, each from a discrete sampling interval.

As discussed above, LFPS is not an option in wells with screened intervals that exceed 5 feet in length, **unless** multiple sample locations at five-foot intervals along the screen/borehole are investigated. Monitor wells screened across zones of significant geologic heterogeneity or open boreholes in fractured rock may be subject to significant vertical flow. Under those conditions, use of packers to isolate specific zones should be considered.

2. Water Quality Indicator Parameters (WQIPs)

For groundwater investigations in New Jersey utilizing LFPS, the following parameters must be measured in order to determine when well stability has been achieved prior to sampling. Their respective measurements must fall within the stated range for three consecutive readings. If the anticipated “third” reading of any individual parameter does not fall within the stated range, then the process to achieve three consecutive readings for that parameter must be restarted. If, after four

hours, stability has not been achieved for the parameters listed below, follow the recommendations above.

Water Level Drawdown	< 0.3 ft*
pH	± 0.1 unit
Specific Conductance	± 3%
Temperature	± 3%
Dissolved Oxygen	± 10%
Turbidity	± 10% for values greater than 1 NTU
ORP/Eh	± 10 millivolts

* During pump start-up, drawdown may exceed the 0.3-ft target and then recover as flow-rate adjustments are made. In wells with short screens (i.e., 5 to 10 ft long) or when sampling for gasoline constituents at the water table, it is much more important to limit the drawdown to less than 0.3 ft, for example, than a well with 15 ft of screen being sampled for metals only with the pump intake set in a permeable zone 5 ft or more below the water table. When sampling groundwater for VOCs and SVOCs, aerating the water by allowing it to cascade down the inside of the well should be avoided. Therefore, drawdown should not expose the screen more than 0.3 ft below the static water level in the well.

Measurements should be taken once every 5 to 6 minutes. This interval is based upon the time it takes for purge water to replace one flow-through-cell volume (generally 250 ml) and the time it takes to measure and record the data. If the purge rate decreases or if the flow cell volume is increased, the time required for purge water replacement will increase. Forms at the end of this document should be used to record drawdown and the WQIPs.

WQIP measurements must be collected in a manner that will insure integrity of the data being collected. To insure consistency of the data, consideration of the following must be made: 1) tubing diameter, length, and material of construction; 2) flow-through cell design, capacity, decontamination, and "purge-train" set-up; 3) pump selection and plumbing fittings; 4) calibration of flow-through cell probes; 5) purge rate; and, 6) water-level-measurement technique.

3. Purge Volume vs. Stabilization Time

In some cases, it may take considerable time to achieve stabilization of the WQIPs. In other cases, they may never stabilize. However, as provided in USEPA guidance, the following options are available if stability has not been achieved after **FOUR** hours of purging: 1) continue purging until stabilization occurs, no matter how long it takes; 2) discontinue purging, do not collect a sample and document the attempts to reach stabilization; or 3) discontinue purging, collect a sample and document the attempts to reach stabilization. In situations where WQIPs do not stabilize, the sampler must document that LFPS could not be performed and document in the report how the samples were collected.

While every effort should be taken to assure that all of the WQIPs stabilize prior to sample collection, one should keep in mind that the stabilization of some WQIPs may be more difficult to achieve than others. Also, achieving stabilization of some WQIPs may be more important with respect to some contaminant types (e.g., metals versus VOCs, etc.) than others. For example, total metals concentrations tend to increase with increasing turbidity of a water sample due to sorption of metals on solids in the water. Similarly, VOC concentrations may be affected by dissolved oxygen (DO) concentrations (i.e., whether the groundwater is aerobic or anaerobic). In addition to providing information on the effectiveness of LFPS, collection of accurate DO data also aids in the evaluation of monitored natural attenuation (MNA) of VOC plumes. Similarly, temperature data can provide useful information regarding the sampling method. For example, temperature increases resulting from dissipation of heat generated by the submersible pump or from exposure of the tubing to excessive heat at the ground surface can have a significant impact on VOC concentrations in water samples.

If, for whatever reason, a WQIP is not accurately measured during the monitoring process or a certain WQIP does not stabilize, and that particular WQIP **is not** significant with respect to the type of contaminant of concern, sample collection may still proceed. For example, if DO data do not stabilize but all of the other WQIPs including drawdown and turbidity stabilize and samples will be collected for metals only, then the samples may be collected. However, any WQIPs that are affected by field conditions or instrument malfunction, must be discussed in the text of the report in order to alert the end-user of potential data bias. If questions arise regarding when stabilization occurs, the sampler should contact the Department's assigned case manager for the site, if any, either prior to (preferably) or when performing LFPS.

4. Tubing

The inside diameter (ID) of tubing should be no greater than three-eighths of an inch (3/8-in). Quarter-inch (1/4-in) tubing is preferred. Larger tubing diameters reduce flow velocity resulting in a corresponding increase of pump speeds to maintain flow. Increased pump speed will, in turn, elevate the potential for turbulent flow across the screened interval and this may affect the quality of the water being sampled. Conversely, any reduction in flow velocity may allow air to become trapped in the tubing, which may ultimately affect air-sensitive parameters or allow particulates to settle, which may affect turbidity values.

The length of tubing, from the top of the well casing to the flow-through chamber, should be the shortest length manageable. Attention to this detail will help ensure that: 1) exposure to ambient temperature, direct sunlight, and bubble formation are kept to a minimum, and 2) deposited solids or air bubbles will less likely be trapped in tubing bends and re-mobilized after accidental movement. Occurrence of any one or combination of these factors can cause variations in WQIP measurements, which could increase stabilization time. Therefore, tubing must be completely full of water at all times.

If the sampling plan calls for multiple sample locations within the well screen, sampling should proceed from the top location to the bottom location. This will require that additional tubing be coiled at the surface to allow for pump relocation to the next deeper sampling location. In these instances,

the coiled tubing must be protected from ambient conditions and the ground surface, in order to avoid impact to the WQIPs and sample data.

The tubing's material of construction must be either Teflon® or Teflon®-lined polyethylene up to the flow-through cell. This is consistent with collection of any groundwater sample. Tubing downstream of the flow cell may be constructed of a lower-quality, more flexible material. However, when sampling for metals analysis only, the tubing may be constructed of flexible polypropylene or polyethylene.

Tubing "reuse" is not recommended when sampling well-to-well since decontamination of tubing is difficult and time consuming. If tubing is to be reused, it must undergo a rigorous decontamination procedure, which must include a hot water wash/hot air drying process. In addition to the hot water wash/hot air drying, separate decontamination solutions of acetone and nitric acid may have to be pumped through the tubing for 15 minutes, followed by copious amounts of distilled, deionized water rinses. The cost of labor associated with decontamination, including the special handling of cleaning solvents and acid, often exceeds the cost of simply discarding the old tubing and using new tubing for each well. If a decision is made to reuse tubing, then one of the following requirements in the USGS "Water-Quality National Field Manual" must be considered: 1) Collect additional field blanks if VOC concentrations in the last sample collected through the tubing are greater than 500 µg/L, or 2) The tubing should be replaced, rather than cleaned, if VOC concentrations in the last sample exceed 700 µg/L.

5. Flow-Through Cell

Typical flow-through cell design is not complicated and almost all on the market today have common shared features. Cells should be transparent in order to "see" the physical condition of the purge water or air bubbles passing through the system. Highly turbid or iron bacteria-laden water can be visually monitored for change as the purge progresses. The cell must be sealed against unwanted exposure to the atmosphere, thus insuring accurate measurement of air-sensitive parameters (dissolved oxygen, pH, etc.). The total capacity of the cell must be small (<300 ml) in order to maintain a desirable turnover rate of water coming into the cell to ensure real-time data integrity. The in-line design must allow for purge water to enter the flow cell from a bottom port and exit at the top. The discharge may be fitted with a check valve.

Upon initial pump startup, it is good practice to not connect the pump discharge line to the flow-through cell. This will allow the sampler time to monitor drawdown, stabilize the flow rate and prevent fowling of probes by bacteria, sediment, or NAPL. Once drawdown measurements indicate that the flow rate has been controlled and a few minutes (<10) have been allowed to clear any unwanted material, the pump discharge line can then be connected to the flow cell.

Flow cell decontamination is important, not only to reduce the potential for cross contamination, but also to ensure data integrity and consistent instrument performance. The cell and probes should be rinsed with distilled/deionized water between each monitor well as accumulation of suspended material may impact probe performance. If they are exposed to contaminants, use a mild detergent or laboratory glassware cleaning solution. Flow cell exposure to high levels of contamination may

damage probes and require their repair by the manufacturer. Since LFPS is NOT normally a first-round sampling option, knowledge of contaminant levels will generally be known prior to the cell's exposure to purge water.

The location of the flow cell or cells in relation to the sample port is critical. Samples for turbidity measurement, general chemistry and laboratory analysis must be collected ahead of the flow cell. When two cells are used in series, the dissolved oxygen probe must be located in the first cell.

Set up the flow-through cell in a location which will cause minimal fluctuation of the flow rate due to elevation changes in the sample tubing as the tubing is disconnected from the cell prior to sample collection. It is also important to locate the flow-through cell as close as possible to the well head in order to minimize the length of tubing needed between the well head and flow-through cell. The flow-through cell must be protected from ambient conditions and the ground surface.

6. Pump Selection

Pumps used for monitoring WQIPs must be submersible, positive-displacement pumps. Examples of acceptable positive-displacement pumps include bladder, variable-speed submersible-centrifugal, reciprocating-piston, progressive-cavity, and gear pumps. The pump discharge must be fitted appropriately to receive either ¼- or 3/8-inch inside-diameter (ID) Teflon® or Teflon®-lined polyethylene tubing.

Peristaltic pumps are suction-lift pumps which can create a negative pressure gradient. Therefore, their use is not appropriate when collecting groundwater samples for analysis of organic compounds. However, peristaltic pumps may be used for the collection of groundwater samples for analysis of inorganic compounds. It should be kept in mind, however, that sampling with peristaltic pumps may affect the stabilization of some WQIPs including dissolved oxygen, pH and redox potential. Since these WQIPs can be affected by the peristaltic pump, this pump should not be used when these data are to be used to evaluate the effectiveness of Monitored Natural Attenuation of groundwater.

Two basic collection scenarios have a bearing on pump selection. These include: 1) a permanently installed pump system, or 2) a portable (well-to-well) pump installation. Bladder pumps can be used for either scenario, however, only those with disposable bladders and easily cleaned parts are suitable when sampling on a well-to-well basis. Variable-speed submersible-centrifugal pumps, gear or progressive-cavity pumps can be used for either scenario as long as they are constructed of easy to clean stainless steel/Teflon® parts. Pumps constructed with impellers, helicoils, or gears, which are difficult to clean or are constructed of unacceptable plastic parts, are not suitable for sampling. In addition, when conducting LFPS on a portable basis, the power or gas supply line should be isolated from the sample tubing. Power supply and sample tubing lines that form a single unit do not allow for easy decontamination and are not recommended.

7. Plumbing Fittings

A check valve should be incorporated into the tubing train or flow cell discharge to eliminate accidental drainage and subsequent aeration of the flow cell. More importantly, a check valve will

prevent a back-surge of purged water being reintroduced at the screen interval of the well should the power source or pump experience mechanical failure. A back-surge of purge water into the screened interval of the well may result in variability of the WQIPs and create analytical bias. In order to avoid the need to decontaminate the check valve, it may be placed on the discharge side of the flow cell or installed immediately above the pump discharge. Some flow-through cells have check valves built into the unit. By design, bladder pumps also have a check valve built into their construction.

A ¼- or 3/8-inch ID barbed "T" or "Y" fitting, placed ahead of the flow cell, may be used to establish the line which will receive a needle valve for turbidity, general chemistry and analytical sample collection. The "T" or "Y" fitting used should be constructed of Teflon® or stainless steel and decontaminated between each use, if used for analytical samples. The fitting may be constructed of polyethylene and decontaminated between each use if it is only used to sample for turbidity and general chemistry parameters. If analytical samples are collected through the "T" or "Y" fitting and needle valve, then those parts must be incorporated into the field blank collection technique.

When collecting a sample at the port ahead of the flow cell, a flow control valve (stainless-steel needle valve [preferred] or stainless steel/Teflon ball valve [optional]) must be used to prevent backpressure and air bubbles from forming in the tubing (see http://water.usgs.gov/owq/FieldManual/chap4_rpt.pdf, page 84). The "needle valve" offers versatility as it can be used for collection of turbidity, general chemistry **and** analytical samples. It can be used with Teflon® tubing and can be used to control sample flow rate because the design significantly reduces any backpressure gradient. Like all other sampling equipment, the "needle valve" must be decontaminated before use at any well.

8. Calibration of Probes

> CALIBRATION OF THE PROBES USED TO MONITOR WATER QUALITY INDICATOR PARAMETERS MUST TAKE PLACE **IN THE FIELD PRIOR** TO THE DAY'S EVENTS. THE OFFICE OF QUALITY ASSURANCE MUST CERTIFY THE PROBES USED FOR pH, DISSOLVED OXYGEN AND TEMPERATURE MEASUREMENT.

There are no exceptions to these rules. Probe calibration is critical to the accurate and precise measurement of WQIPs.

For warranty purposes, **all** manufacturers' instructions for proper care and calibration must be followed. Solutions for probe calibration must be held to the temperature of the liquid (groundwater) being measured as temperature correlation is critical in calculating conductivity, dissolved oxygen and pH. Tables and equations to compensate for the difference between ambient groundwater and calibration solution temperature are sometimes provided in the operating manuals or with the calibration solutions. Some instruments are designed with internal features to compensate for this difference in temperature. The respective difference between calibration of conductivity and specific conductivity requires compensation for groundwater temperature at the time of calibration vs. solution temperature adjusted to 25°C at the time of calibration. For dissolved oxygen, the flow cell itself must

be maintained at the temperature of groundwater during calibration. All efforts made to account for proper temperature control of solutions during calibration must be reported to the end user. All steps must be recorded in the field notes. No sampling shall commence until all instruments are calibrated and operating properly. See the "Tips" section below for further discussion on Temperature of Calibration Solutions.

9. Water Level Measurements

The depth to the top of the water column must be recorded prior to pump installation and/or prior to purging. If the **total** depth of the well needs to be determined (e.g., to verify the correct well designation and/or to determine if silt has accumulated in the bottom of a well), it should be measured at least 48 hours prior to sample collection or after the sample has been collected and the pump removed. Total depth measurements must never be taken immediately before purging as this may cause the re-suspension of solids in the well and prolong the purge time.

Once the initial water-level measurement has been recorded and the pump installed, suspend the water-level probe in the well at the point at which drawdown is equivalent to a 0.3-foot drop. Record water levels simultaneously with WQIP measurements once every five minutes.

Water-level-measurement devices, which may impart some disturbance to the water column (i.e., stainless steel “popper” or coated tape), are not acceptable.

10. Pump Installation

LFPS pump installation can be divided into two general collection scenarios: permanent and portable (well-to-well). Permanent pump installation is the most desirable. Among other advantages are improved consistency in data acquisition and reduced long-term labor, preparation and material costs. However, permanent installation is more typically associated with long-term monitoring due to the high initial capital investment required.

The more common practice is to use a pump on a portable or well-to-well basis. While initial capital investment is comparatively less than that of a permanent installation, this practice requires close attention to quality control aspects of pump selection, preparation and decontamination.

Once pumps have been properly decontaminated and fitted with appropriate tubing, installation of the pump can begin. Ideally, pumps should be installed 24 to 48 hours prior to initiation of purging. However, this is not always practical, especially when site security can not be guaranteed. In addition, wells constructed with flush-mount casing are difficult to protect from storm water or infiltration of other contaminants during the extended period monitor wells are open.

Pumps must be installed in such a manner as to insure any disturbance in the well is kept to an absolute minimum. Once pumps reach the top of the water column, their descent should proceed very slowly through the water column. The actual level where the pump intake is to be suspended must be predetermined. Under no circumstance should the pump make contact with, or be “bounced” off, the bottom of the well.

One helpful method to insure proper intake location is to accurately measure and pre-cut the tubing for each individual well prior to site activity. A mark can be made on the tubing, which coincides with the top of the well. Cutting the tubing off-site in a controlled setting is most desirable. Tubing can be wiped down with paper towels, moistened with distilled/ deionized water, labeled and then sealed into plastic bags until needed. If this practice is used, be sure to allow enough tubing to account for the distance from the top of the well casing to the flow cell.

11. Purge Rates

Control over the purge rate is one of the most critical aspects of this technique. Once the pump is set within the screened interval at the desired location, a clean electronic water-level-monitoring device is lowered approximately 0.3 ft into the water column. Start the pump at a speed that results in a flow rate in the range of 100 to 500 ml/min. Pump the initial purge water to waste in order to prevent any fouling of the flow-through cell. *With the pump running,* connect the tubing to the cell. Make sure that all air is purged from the tubing and flow cell as the system fills with purge water. For LFPS, the pump speed must remain constant such that flow rates never exceed 500 ml/min and, once stabilized, the flow rate must not be varied, even during sample collection. If drawdown continues to exceed 0.3 ft., reduce the pump speed until the drawdown has stabilized but do not adjust pump speed to a flow rate below 100 ml/min. Flow rates below this level may induce pump stalling and undo the effort to reach stabilization. If drawdown does not come under control at 100 ml/min, then a field decision should be rendered as to how far to allow drawdown to continue until sample collection. At no time should evacuation allow any portion of the well screen to be exposed (for wells screened below the water table) or bring the well to dryness.

Adjustments to pump speed are best made during the first 15 minutes. Once a "feel" for the purge rate is obtained, begin recording well stabilization indicators. Any significant change to purge rates after this time may negatively impact well stabilization measurements.

Purge rates are best monitored by measuring the flow from the discharge side of the flow cell with a graduated cylinder. Record all of the required WQIPs once every 5 minutes. Once stability has been attained and recorded, begin sample collection

12. Sampling

Once WQIPs have stabilized, or a 4-hour time decision has been rendered, sampling can proceed. Do not adjust the flow rate; maintain the same pumping rate during sampling that was used to purge the well. Collect the sample directly from the needle valve at the sample port. The needle valve allows for sample collection with significantly reduced backpressure and turbulence and offers the best means for sample collection without affecting water quality. It also allows for monitoring using the flow-through cell during sample collection, thereby allowing a final WQIP measurement to be recorded immediately after sample collection. This is the preferred method, especially if volatile organic compounds are the parameters of concern. Any exceptions to this technique must first be approved in writing from the NJDEP on a case-by-case basis before commencing sampling operations.

If higher than expected water temperatures are being observed, evaluate whether the submersible pump is overheating. If the pump motor is not suspected, check the system for any exposure to direct sunlight, especially during warmer periods of the year.

13. Pump Decontamination

The pump forms one of the two key elements of sampling equipment (tubing is the other). The importance of proper pump decontamination is especially true when pumps are rented and utilized on a well-to-well basis. Never assume that rented pumps have been thoroughly cleaned. **Pumps constructed with plastic parts, or sealed inner workings that are inaccessible to direct handling are not an option for LFPS well-to-well consideration because of their limited ability to be decontaminated thoroughly**.

Most bladder pumps can not be easily decontaminated in the field due to their unique construction. For that reason, bladder pumps are not employed on a well-to-well basis **unless** they are constructed with easy to clean parts and *disposable* bladders. Bladder pumps are best suited for dedicated (permanently installed) scenarios. Another popular pump, the variable-speed, 2-inch diameter submersible, is more adaptable for well-to-well sampling; however, close attention to decontamination is warranted. One manufacturer, Grundfos®, clearly states in the operational handbook that the pump must be completely disassembled, including removal of the motor shaft from the stator housing, and all components within the impeller housing. Care must be taken upon reassembly to insure that the cavity housing the motor shaft is *completely* refilled with distilled/deionized water. Care must also be taken with this pump during periods of cold weather to avoid freezing of the coolant water. Proper decontamination not only helps to ensure more reliable data; it also prolongs the life of any pump.

14. Field Blank Collection

When employing LFPS techniques, collection of the field blank must follow the same general rules for all groundwater sampling equipment. This includes the requirement that "all" sampling equipment, which comes in contact with the sample, must also come into contact with the field blank water. To overcome some of the difficulties that manual field blank collection through the inside of a pumping system creates, the following procedure is strongly recommended. Fill a 1000-ml decontaminated, graduated glass cylinder with method blank water supplied by the laboratory performing the analysis. Place a properly decontaminated pump into the graduated cylinder with sample tubing and plumbing fittings attached. Activate the pump and collect the required field blank samples. As the water is removed from the cylinder, replace it with additional method blank water. This procedure will require that the laboratory supply larger volumes of field blank water i.e., bulk water in liter or 4-liter containers. The traditional requirement that field blank water be supplied in the same identical containers as the sample being collected can not be practically satisfied when using LFSP. The identical bottle-to-bottle field blank requirement is waived for this sampling technique procedure only.

15. Tips

a). Temperature Measurement and Submersible Pumps

Variable-speed submersible pumps such as the Grundfos® Redi Flo 2 pump use water to cool the motor during operation. Sometimes, reduced flow rates may result in insufficient cooling of the motor and may elevate the temperature of the water to a point where it may begin to affect sample integrity. If the pump is used in low-yielding, two (2)- or four (4)- inch-diameter wells, temperature increases that do not stabilize may result. If this is observed, a field decision must be made to either discontinue or continue with LFPS. If all other WQIPs have stabilized, then collecting the sample and qualifying the water-quality data accordingly may be acceptable. If the temperature increase continues and eventually exceeds 40% of the initial recorded temperature (Celsius) and other WQIPs have not stabilized, sampling should be discontinued. Turning the pump off and on to control overheating is not acceptable. Always keep in mind that elevated temperature has a direct relationship with dissolved oxygen, specific conductance and, to a lesser degree, pH measurement. Higher temperatures may also reduce the concentrations of volatile organic compounds in groundwater samples due to their relatively high Henry's Law constants. If sampling with submersible pumps continues to result in elevated water temperature, other sampling alternatives should be discussed with the appropriate regulatory program.

When using some submersible pumps in large-diameter wells (six inch and greater), overheating of the motor, followed by mechanical shutdown and possible motor damage, may occur. This is the result of water being drawn to the pump intake in a more horizontal flow pattern which diminishes the design feature that normally moves cool water vertically across the motor (stator) housing. The use of specially designed shrouds may overcome this condition.

b). Control of Pump Speed

In order to achieve the high turning speeds, low-speed startup torque is generally lacking in some submersible pumps including the Grundfos® Redi Flo 2 pump. When attempting to control initial drawdown and/or sample flow rates, it is possible for the pump to cease pumping. Then, if a check valve has been installed, the pump may not have enough torque to overcome the head pressure when attempting to restart it. Sometimes, turning the pump to the highest speeds will overcome this situation or sometimes the pump may have to be pulled from the well and reinstalled. Neither of these corrective measures is conducive to LFPS. To avoid this scenario, make sure the control box comes equipped with a "ten turn pot" frequency adjustment knob. This will allow significantly greater control over pump speeds and the risk of losing pump flow will be reduced.

c). pH

Monitoring for stabilization of pH in groundwater is relatively straightforward and rarely requires serious troubleshooting. When calibrating for pH, do a two-point calibration, at a minimum. The calibration range should bracket the anticipated pH. If the pH is unknown, then a three-point calibration must be made. The temperature of the buffer solutions should be as close to the

temperature of the groundwater as possible. If the probe does not calibrate properly, check to make sure that the probe's electrical contact points are dry. As with preventative maintenance of any probe, make sure that the pH probe is rinsed with distilled/deionized water between use and cleaned periodically per the manufacturer's specifications. Overnight storage generally requires placement of the probe into a 2-molar (M) solution of potassium chloride. This solution may cause an unwanted build up of salt, therefore, frequent rinsing is necessary.

d). Temperature of Calibration Solutions

Correct field measurement of dissolved oxygen, conductivity and pH requires tight control over calibration solution temperature. Proper calibration calls for solution temperatures of these parameters to be the same as the groundwater being measured. This may be difficult to achieve when field sampling well-to-well as groundwater temperature can vary between wells based on depth, local setting (asphalt vs. open field) and other atmospheric and hydrogeological factors. In addition, it is logistically difficult to bring solutions to groundwater temperature at the point of pump intake without first installing the pump, collecting purge water and allowing sufficient time to bring calibration solutions to appropriate temperatures.

For the purposes of LFPS in New Jersey, calibration solution temperatures and the flow-through cell itself must be maintained at approximately 54° F (12° C ± 2° C) during calibration. When ambient conditions warrant, this will require the suspension of the solutions and flow-through cell in a container/bucket of water at the aforementioned temperature. When calibrating for dissolved oxygen, always make sure the cell is vented to the atmosphere by attaching short pieces of tubing to the inlet and outlet fittings while the cell is submerged.

During the purge phase, record the difference between the stabilized temperature and the temperature of the calibration solutions. This information must be presented to the end user. If the sampling event is extended for two or more days, appropriate adjustments can then be made to more accurately reflect the groundwater temperature during calibration.

16. Low Flow Purging and Sampling for Low Yielding Wells

The principal focus of water supply well installation is well yield. In contrast, the principal focus of monitor well installation is water quality; well yield is of secondary importance. In an attempt to locate and delineate groundwater contamination, monitor wells are frequently installed in low-yielding water-bearing zones.

Low-yield wells present challenges with respect to representative groundwater sample collection. The removal of water by bailers draws down the water level in the well by slug- type increments. Peristaltic pumps draw water out of the well by vacuum (negative pressure) which may result in degassing and VOC loss. The operation of variable-speed, submersible pumps at low flow rates may result in heating of the sample as it flows around and through the pump, which may also lead to degassing and VOC loss.

Wells that yield less than 0.1 l/min (100ml/min) frequently incur significant drawdown during well purging. If drawdown occurs across the screened interval or open borehole of a well, VOC loss may result. The increased stress on a well caused by significant drawdown may also result in an increase in water turbidity. In an effort to facilitate the collection of a representative groundwater sample from low-yielding wells, NJDEP will allow special sampling procedures to be used. This may include sample collection without regard to monitoring WQIPs associated with well stabilization.

At a minimum, water-quality data, well-construction data, water-level data, and accurate well-yield data for each low-yielding well will need to be submitted to the Department prior to the development of an acceptable sampling procedure. Since sample collection may begin almost as soon as purging is initiated, it is imperative that the exact interval where the sample will be collected along the screen be predetermined. Aside from the considerations for monitoring drawdown and WQIPs, all other LFPS considerations discussed above apply here as well. The owner of the well shall also propose possible explanations for the low yield of the well(s). Once the aforementioned information has been received, the Department will work with the well owner to formulate an acceptable sampling plan. The sampling plans will be approved on a case-by-case basis and will be well-specific. Implementation of any special sampling procedure or use of any special sampling equipment shall not be performed without prior NJDEP approval.

LOW-FLOW (MINIMAL DRAWDOWN) GROUND-WATER SAMPLING PROCEDURES

by Robert W. Puls[1] and Michael J. Barcelona[2]

Background

The Regional Superfund Ground Water Forum is a group of ground-water scientists, representing EPA's Regional Superfund Offices, organized to exchange information related to ground-water remediation at Superfund sites. One of the major concerns of the Forum is the sampling of ground water to support site assessment and remedial performance monitoring objectives. This paper is intended to provide background information on the development of low-flow sampling procedures and its application under a variety of hydrogeologic settings. It is hoped that the paper will support the production of standard operating procedures for use by EPA Regional personnel and other environmental professionals engaged in ground-water sampling.

For further information contact: Robert Puls, 405-436-8543, Subsurface Remediation and Protection Division, NRMRL, Ada, Oklahoma.

I. Introduction

The methods and objectives of ground-water sampling to assess water quality have evolved over time. Initially the emphasis was on the assessment of water quality of aquifers as sources of drinking water. Large water-bearing units were identified and sampled in keeping with that objective. These were highly productive aquifers that supplied drinking water via private wells or through public water supply systems. Gradually, with the increasing awareness of subsurface pollution of these water resources, the understanding of complex hydrogeochemical processes which govern the fate and transport of contaminants in the subsurface increased. This increase in understanding was also due to advances in a number of scientific disciplines and improvements in tools used for site characterization and ground-water sampling. Ground-water quality investigations where pollution was detected initially borrowed ideas, methods, and materials for site characterization from the water supply field and water analysis from public health practices. This included the materials and manner in which monitoring wells were installed and the way in which water was brought to the surface, treated, preserved and analyzed. The prevailing conceptual ideas included convenient generalizations of ground-water resources in terms of large and relatively homogeneous hydrologic *units*. With time it became apparent that conventional water supply generalizations of *homogeneity* did not adequately represent field data regarding pollution of these subsurface resources. The important role of *heterogeneity* became increasingly clear not only in geologic terms, but also in terms of complex physical,

chemical and biological subsurface processes. With greater appreciation of the role of heterogeneity, it became evident that subsurface pollution was ubiquitous and encompassed the unsaturated zone to the deep subsurface and included unconsolidated sediments, fractured rock, and *aquitards* or low-yielding or impermeable formations. Small-scale processes and heterogeneities were shown to be important in identifying contaminant distributions and in controlling water and contaminant flow paths.

It is beyond the scope of this paper to summarize all the advances in the field of ground-water quality investigations and remediation, but two particular issues have bearing on ground-water sampling today: aquifer heterogeneity and colloidal transport. Aquifer heterogeneities affect contaminant flow paths and include variations in geology, geochemistry, hydrology and microbiology. As methods and the tools available for subsurface investigations have become increasingly sophisticated and understanding of the subsurface environment has advanced, there is an awareness that in most cases a primary concern for site investigations is characterization of contaminant flow paths rather than entire aquifers. In fact, in many cases, plume thickness can be less than well screen lengths (e.g., 3-6 m) typically installed at hazardous waste sites to detect and monitor plume movement over time. Small-scale differences have increasingly been shown to be important and there is a general trend toward smaller diameter wells and shorter screens.

The hydrogeochemical significance of colloidal-size particles in subsurface systems has been realized during the past several years (Gschwend and Reynolds, 1987; McCarthy and Zachara, 1989; Puls, 1990; Ryan and Gschwend, 1990). This realization resulted from both field and laboratory studies that showed faster contaminant migration over greater distances and at higher concentrations than flow and transport model predictions would suggest (Buddemeier and Hunt, 1988; Enfield and Bengtsson, 1988; Penrose et al., 1990). Such models typically account for interaction between the mobile aqueous and immobile solid phases, but do not allow for a mobile, reactive solid phase. It is recognition of this third *phase* as a possible means of contaminant transport that has brought increasing attention to the manner in which samples are collected and processed for analysis (Puls et al., 1990; McCarthy and Degueldre, 1993; Backhus et al., 1993; U. S. EPA, 1995). If such a phase is present in sufficient mass, possesses high sorption reactivity, large surface area, and remains stable in suspension, it can serve as an important mechanism to facilitate contaminant transport in many types of subsurface systems.

Colloids are particles that are sufficiently small so that the surface free energy of the particle dominates the bulk free energy. Typically, in ground water, this includes particles with diameters between 1 and 1000 nm. The most commonly observed mobile particles include: secondary clay minerals; hydrous iron, aluminum, and manganese oxides; dissolved and particulate organic materials, and viruses and bacteria. These reactive particles have been shown to be mobile under a variety of conditions in both field studies and laboratory column experiments, and as such need to be included in monitoring programs where identification of the *total* mobile contaminant loading (dissolved + naturally suspended particles) at a site is an objective. To that end, sampling methodologies must be used which do not artificially bias *naturally* suspended particle concentrations.

Currently the most common ground-water purging and sampling methodology is to purge a well using bailers or high speed pumps to remove 3 to 5 casing volumes followed by sample collection. This method can cause adverse impacts on sample quality through collection of samples with high levels of turbidity. This results in the inclusion of otherwise immobile artifactual particles which produce an overestimation of certain analytes of interest (e.g., metals or hydrophobic organic compounds). Numerous documented problems associated with filtration (Danielsson, 1982; Laxen and Chandler, 1982; Horowitz et al., 1992) make this an undesirable method of rectifying the turbidity problem, and include the removal of potentially mobile (contaminant-associated) particles during filtration, thus artificially biasing contaminant concentrations low. Sampling-induced turbidity problems can often be mitigated by using low-flow purging and sampling techniques.

Current subsurface conceptual models have undergone considerable refinement due to the recent development and increased use of field screening tools. So-called hydraulic *push* technologies (e.g., cone penetrometer, Geoprobe®, QED HydroPunch®) enable relatively fast screening site characterization which can then be used to design and install a monitoring well network. Indeed, alternatives to conventional monitoring wells are now being considered for some hydrogeologic settings. The ultimate design of any monitoring system should however be based upon adequate site characterization and be consistent with established monitoring objectives.

If the sampling program objectives include accurate assessment of the magnitude and extent of subsurface contamination over time and/or accurate assessment of subsequent remedial performance, then some information regarding plume delineation in three-dimensional space is necessary prior to monitoring well network design and installation. This can be accomplished with a variety of different tools and equipment ranging from hand-operated augers to screening tools mentioned above and large drilling rigs. Detailed information on ground-water flow velocity, direction, and horizontal and vertical variability are essential baseline data requirements. Detailed soil and geologic data are required prior to and during the installation of sampling points. This includes historical as well as detailed soil and geologic logs which accumulate during the site investigation. The use of borehole geophysical techniques is also recommended. With this information (together with other site characterization data) and a clear understanding of sampling

objectives, then appropriate location, screen length, well diameter, slot size, etc. for the monitoring well network can be decided. This is especially critical for new in situ remedial approaches or natural attenuation assessments at hazardous waste sites.

In general, the overall goal of any ground-water sampling program is to collect water samples with no alteration in water chemistry; analytical data thus obtained may be used for a variety of specific monitoring programs depending on the regulatory requirements. The sampling methodology described in this paper assumes that the monitoring goal is to sample monitoring wells for the presence of contaminants and it is applicable whether mobile colloids are a concern or not and whether the analytes of concern are metals (and metalloids) or organic compounds.

II. Monitoring Objectives and Design Considerations

The following issues are important to consider prior to the design and implementation of any ground-water monitoring program, including those which anticipate using low-flow purging and sampling procedures.

A. Data Quality Objectives (DQOs)

Monitoring objectives include four main types: detection, assessment, corrective-action evaluation and resource evaluation, along with *hybrid* variations such as site-assessments for property transfers and water availability investigations. Monitoring objectives may change as contamination or water quality problems are discovered. However, there are a number of common components of monitoring programs which should be recognized as important regardless of initial objectives. These components include:

1) Development of a conceptual model that incorporates elements of the regional geology to the local geologic framework. The conceptual model development also includes initial site characterization efforts to identify hydrostratigraphic units and likely flow-paths using a minimum number of borings and well completions;

2) Cost-effective and well documented collection of high quality data utilizing simple, accurate, and reproducible techniques; and

3) Refinement of the conceptual model based on supplementary data collection and analysis.

These fundamental components serve many types of monitoring programs and provide a basis for future efforts that evolve in complexity and level of spatial detail as purposes and objectives expand. High quality, reproducible data collection is a common goal regardless of program objectives.

High quality data collection implies data of sufficient accuracy, precision, and completeness (i.e., ratio of valid analytical results to the minimum sample number called for by the program design) to meet the program objectives. Accuracy depends on the correct choice of monitoring tools and procedures to minimize sample and subsurface disturbance from collection to analysis. Precision depends on the repeatability of sampling and analytical protocols. It can be assured or improved by replication of sample analyses including blanks, field/lab standards and reference standards.

B. Sample Representativeness

An important goal of any monitoring program is collection of data that is truly representative of conditions at the site. The term *representativeness* applies to chemical and hydrogeologic data collected via wells, borings, piezometers, geophysical and soil gas measurements, lysimeters, and temporary sampling points. It involves a recognition of the statistical variability of individual subsurface physical properties, and contaminant or major ion concentration levels, while explaining extreme values. Subsurface temporal and spatial variability are facts. Good professional practice seeks to maximize representativeness by using proven accurate and reproducible techniques to define limits on the distribution of measurements collected at a site. However, measures of representativeness are dynamic and are controlled by evolving site characterization and monitoring objectives. An evolutionary site characterization model, as shown in Figure 1, provides a systematic approach to the goal of consistent data collection.

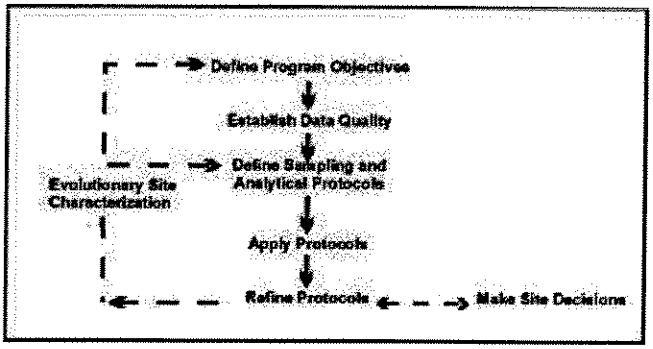

Figure 1. Evolutionary Site Characterization Model

The model emphasizes a recognition of the causes of the variability (e.g., use of inappropriate technology such as using bailers to purge wells; imprecise or operator-dependent methods) and the need to control avoidable errors.

1) Questions of Scale

A sampling plan designed to collect representative samples must take into account the potential scale of changes in site conditions through space and time as well as the chemical associations and behavior of the parameters that are targeted for investigation. In subsurface systems, physical (i.e., aquifer) and chemical properties over time or space are not statistically independent. In fact, samples taken in close proximity (i.e., within distances of a few meters) or within short time periods (i.e., more frequently than monthly) are highly auto-correlated. This means that designs employing high-sampling frequency (e.g., monthly) or dense spatial monitoring designs run the risk of redundant data collection and misleading inferences regarding trends in values that aren't statistically valid. In practice, contaminant detection and assessment monitoring programs rarely suffer these *over-sampling* concerns. In corrective-action evaluation programs, it is also possible that too little data may be collected over space or time. In these cases, false interpretation of the spatial extent of contamination or underestimation of temporal concentration variability may result.

2) Target Parameters

Parameter selection in monitoring program design is most often dictated by the regulatory status of the site. However, background water quality constituents, purging indicator parameters, and contaminants, all represent targets for data collection programs. The tools and procedures used in these programs should be equally rigorous and applicable to all categories of data, since all may be needed to determine or support regulatory action.

C. Sampling Point Design and Construction

Detailed site characterization is central to all decision-making purposes and the basis for this characterization resides in identification of the geologic framework and major hydro-stratigraphic units. Fundamental data for sample point location include: subsurface lithology, head-differences and background geochemical conditions. Each sampling point has a proper use or uses which should be documented at a level which is appropriate for the program's data quality objectives. Individual sampling points may not always be able to fulfill multiple monitoring objectives (e.g., detection, assessment, corrective action).

1) Compatibility with Monitoring Program and Data Quality Objectives

Specifics of sampling point location and design will be dictated by the complexity of subsurface lithology and variability in contaminant and/or geochemical conditions. It should be noted that, regardless of the ground-water sampling approach, few sampling points (e.g., wells, drive-points, screened augers) have zones of influence in excess of a few feet. Therefore, the spatial frequency of sampling points should be carefully selected and designed.

2) Flexibility of Sampling Point Design

In most cases *well-point* diameters in excess of 1 7/8 inches will permit the use of most types of submersible pumping devices for low-flow (minimal drawdown) sampling. It is suggested that *short* (e.g., less than 1.6 m) screens be incorporated into the monitoring design where possible so that comparable results from one device to another might be expected. *Short*, of course, is relative to the degree of vertical water quality variability expected at a site.

3) Equilibration of Sampling Point

Time should be allowed for equilibration of the well or sampling point with the formation after installation. Placement of well or sampling points in the subsurface produces some disturbance of ambient conditions. Drilling techniques (e.g., auger, rotary, etc.) are generally considered to cause more disturbance than *direct-push* technologies. In either case, there may be a period (i.e., days to months) during which water quality near the point may be distinctly different from that in the formation. Proper development of the sampling point and adjacent formation to remove fines created during emplacement will shorten this water quality *recovery* period.

III. Definition of Low-Flow Purging and Sampling

It is generally accepted that water in the well casing is non-representative of the formation water and needs to be purged prior to collection of ground-water samples. However, the water in the screened interval may indeed be representative of the formation, depending upon well construction and site hydrogeology. Wells are purged to some extent for the following reasons: the presence of the air interface at the top of the water column resulting in an oxygen concentration gradient with depth, loss of volatiles up the water column, leaching from or sorption to the casing or filter pack, chemical changes due to clay seals or backfill, and surface infiltration.

Low-flow purging, whether using portable or dedicated systems, should be done using pump-intake located in the middle or slightly above the middle of the screened interval. Placement of the pump too close to the bottom of the well will cause increased entrainment of solids which have collected in the well over time. These particles are present as a result of well development, prior purging and sampling events, and natural colloidal transport and deposition. Therefore, placement of the pump in the middle or toward the top of the screened interval is suggested. Placement of the pump at the top of the water column for sampling is only recommended in unconfined aquifers, screened across the water table, where this is the desired sampling point. Low-

flow purging has the advantage of minimizing mixing between the overlying stagnant casing water and water within the screened interval.

A. Low-Flow Purging and Sampling

Low-flow refers to the velocity with which water enters the pump intake and that is imparted to the formation pore water in the immediate vicinity of the well screen. It does not necessarily refer to the flow rate of water discharged at the surface which can be affected by flow regulators or restrictions. Water level drawdown provides the best indication of the stress imparted by a given flow-rate for a given hydrological situation. The objective is to pump in a manner that minimizes stress (drawdown) to the system to the extent practical taking into account established site sampling objectives. Typically, flow rates on the order of 0.1 - 0.5 L/min are used, however this is dependent on site-specific hydrogeology. Some extremely coarse-textured formations have been successfully sampled in this manner at flow rates to 1 L/min. The effectiveness of using low-flow purging is intimately linked with proper screen location, screen length, and well construction and development techniques. The reestablishment of natural flow paths in both the vertical and horizontal directions is important for correct interpretation of the data. For high resolution sampling needs, screens less than 1 m should be used. Most of the need for purging has been found to be due to passing the sampling device through the overlying casing water which causes mixing of these stagnant waters and the dynamic waters within the screened interval. Additionally, there is disturbance to suspended sediment collected in the bottom of the casing and the displacement of water out into the formation immediately adjacent to the well screen. These disturbances and impacts can be avoided using dedicated sampling equipment, which precludes the need to insert the sampling device prior to purging and sampling.

Isolation of the screened interval water from the overlying stagnant casing water may be accomplished using low-flow minimal drawdown techniques. If the pump intake is located within the screened interval, most of the water pumped will be drawn in directly from the formation with little mixing of casing water or disturbance to the sampling zone. However, if the wells are not constructed and developed properly, zones other than those intended may be sampled. At some sites where geologic heterogeneities are sufficiently different within the screened interval, higher conductivity zones may be preferentially sampled. This is another reason to use shorter screened intervals, especially where high spatial resolution is a sampling objective.

B. Water Quality Indicator Parameters

It is recommended that water quality indicator parameters be used to determine purging needs prior to sample collection in each well. Stabilization of parameters such as pH, specific conductance, dissolved oxygen, oxidation-reduction potential, temperature and turbidity should be used to determine when formation water is accessed during purging. In general, the order of stabilization is pH, temperature, and specific conductance, followed by oxidation-reduction potential, dissolved oxygen and turbidity. Temperature and pH, while commonly used as purging indicators, are actually quite insensitive in distinguishing between formation water and stagnant casing water; nevertheless, these are important parameters for data interpretation purposes and should also be measured. Performance criteria for determination of stabilization should be based on water-level drawdown, pumping rate and equipment specifications for measuring indicator parameters. Instruments are available which utilize in-line flow cells to continuously measure the above parameters.

It is important to establish specific well stabilization criteria and then consistently follow the same methods thereafter, particularly with respect to drawdown, flow rate and sampling device. Generally, the time or purge volume required for parameter stabilization is independent of well depth or well volumes. Dependent variables are well diameter, sampling device, hydrogeochemistry, pump flow rate, and whether the devices are used in a portable or dedicated manner. If the sampling device is already in place (i.e., dedicated sampling systems), then the time and purge volume needed for stabilization is much shorter. Other advantages of dedicated equipment include less purge water for waste disposal, much less decontamination of equipment, less time spent in preparation of sampling as well as time in the field, and more consistency in the sampling approach which probably will translate into less variability in sampling results. The use of dedicated equipment is strongly recommended at wells which will undergo routine sampling over time.

If parameter stabilization criteria are too stringent, then minor oscillations in indicator parameters may cause purging operations to become unnecessarily protracted. It should also be noted that turbidity is a very conservative parameter in terms of stabilization. Turbidity is always the last parameter to stabilize. Excessive purge times are invariably related to the establishment of too stringent turbidity stabilization criteria. It should be noted that natural turbidity levels in ground water may exceed 10 nephelometric turbidity units (NTU).

C. Advantages and Disadvantages of Low-Flow (Minimum Drawdown) Purging

In general, the advantages of low-flow purging include:

- samples which are representative of the *mobile* load of contaminants present (dissolved and colloid-associated);
- minimal disturbance of the sampling point thereby minimizing sampling artifacts;
- less operator variability, greater operator control;

- reduced stress on the formation (minimal drawdown);
- less mixing of stagnant casing water with formation water;
- reduced need for filtration and, therefore, less time required for sampling;
- smaller purging volume which decreases waste disposal costs and sampling time;
- better sample consistency; reduced artificial sample variability.

Some disadvantages of low-flow purging are:

- higher initial capital costs,
- greater set-up time in the field,
- need to transport additional equipment to and from the site,
- increased training needs,
- resistance to change on the part of sampling practitioners,
- concern that new data will indicate a *change in conditions* and trigger an *action.*

IV. Low-Flow (Minimal Drawdown) Sampling Protocols

The following ground-water sampling procedure has evolved over many years of experience in ground-water sampling for organic and inorganic compound determinations and as such summarizes the authors' (and others) experiences to date (Barcelona et al., 1984, 1994; Barcelona and Helfrich, 1986; Puls and Barcelona, 1989; Puls et. al. 1990, 1992; Puls and Powell, 1992; Puls and Paul, 1995). High-quality chemical data collection is essential in ground-water monitoring and site characterization. The primary limitations to the collection of *representative* ground-water samples include: mixing of the stagnant casing and *fresh* screen waters during insertion of the sampling device or ground-water level measurement device; disturbance and resuspension of settled solids at the bottom of the well when using high pumping rates or raising and lowering a pump or bailer; introduction of atmospheric gases or degassing from the water during sample handling and transfer, or inappropriate use of vacuum sampling device, etc.

A. Sampling Recommendations

Water samples should not be taken immediately following well development. Sufficient time should be allowed for the ground-water flow regime in the vicinity of the monitoring well to stabilize and to approach chemical equilibrium with the well construction materials. This lag time will depend on site conditions and methods of installation but often exceeds one week.

Well purging is nearly always necessary to obtain samples of water flowing through the geologic formations in the screened interval. Rather than using a general but arbitrary guideline of purging three casing volumes prior to sampling, it is recommended that an in-line water quality measurement device (e.g., flow-through cell) be used to establish the stabilization time for several parameters (e.g. , pH, specific conductance, redox, dissolved oxygen, turbidity) on a well-specific basis. Data on pumping rate, drawdown, and volume required for parameter stabilization can be used as a guide for conducting subsequent sampling activities.

The following are recommendations to be considered before, during and after sampling:

- use low-flow rates (<0.5 L/min), during both purging and sampling to maintain minimal drawdown in the well;
- maximize tubing wall thickness, minimize tubing length;
- place the sampling device intake at the desired sampling point;
- minimize disturbances of the stagnant water column above the screened interval during water level measurement and sampling device insertion;
- make proper adjustments to stabilize the flow rate as soon as possible;
- monitor water quality indicators during purging;
- collect unfiltered samples to estimate contaminant loading and transport potential in the subsurface system.

B. Equipment Calibration

Prior to sampling, all sampling device and monitoring equipment should be calibrated according to manufacturer's recommendations and the site Quality Assurance Project Plan (QAPP) and Field Sampling Plan (FSP). Calibration of pH should be performed with at least two buffers which bracket the expected range. Dissolved oxygen calibration must be corrected for local barometric pressure readings and elevation.

C. Water Level Measurement and Monitoring

It is recommended that a device be used which will least disturb the water surface in the casing. Well depth should be obtained from the well logs. Measuring to the bottom of the well casing will only cause resuspension of settled solids from the formation and require longer purging times for turbidity equilibration. Measure well depth after sampling is completed. The water level measurement should be taken from a permanent reference point which is surveyed relative to ground elevation.

D. Pump Type

The use of low-flow (e.g., 0.1-0.5 L/min) pumps is suggested for purging and sampling all types of analytes. All pumps have some limitation and these should be investigated with respect to application at a particular site. Bailers are inappropriate devices for low-flow sampling.

1) General Considerations

There are no unusual requirements for ground-water sampling devices when using low-flow, minimal drawdown techniques. The major concern is that the device give consistent results and minimal disturbance of the sample across a range of *low* flow rates (i.e., < 0.5 L/min). Clearly, pumping rates that cause minimal to no drawdown in one well could easily cause *significant* drawdown in another well finished in a less transmissive formation. In this sense, the pump should not cause undue pressure or temperature changes or physical disturbance on the water sample over a reasonable sampling range. Consistency in operation is critical to meet accuracy and precision goals.

2) Advantages and Disadvantages of Sampling Devices

A variety of sampling devices are available for low-flow (minimal drawdown) purging and sampling and include peristaltic pumps, bladder pumps, electrical submersible pumps, and gas-driven pumps. Devices which lend themselves to both dedication and consistent operation at definable low-flow rates are preferred. It is desirable that the pump be easily adjustable and operate reliably at these lower flow rates. The peristaltic pump is limited to shallow applications and can cause degassing resulting in alteration of pH, alkalinity, and some volatiles loss. Gas-driven pumps should be of a type that does not allow the gas to be in direct contact with the sampled fluid.

Clearly, bailers and other *grab* type samplers are ill-suited for low-flow sampling since they will cause repeated disturbance and mixing of *stagnant* water in the casing and the *dynamic* water in the screened interval. Similarly, the use of inertial lift foot-valve type samplers may cause too much disturbance at the point of sampling. Use of these devices also tends to introduce uncontrolled and unacceptable operator variability.

Summaries of advantages and disadvantages of various sampling devices are listed in Herzog et al. (1991), U. S. EPA (1992), Parker (1994) and Thurnblad (1994).

E. Pump Installation

Dedicated sampling devices (left in the well) capable of pumping and sampling are preferred over <u>any</u> other type of device. Any portable sampling device should be slowly and carefully lowered to the middle of the screened interval or slightly above the middle (e.g., 1-1.5 m below the top of a 3 m screen). This is to minimize excessive mixing of the stagnant water in the casing above the screen with the screened interval zone water, and to minimize resuspension of solids which will have collected at the bottom of the well. These two disturbance effects have been shown to directly affect the time required for purging. There also appears to be a direct correlation between size of portable sampling devices relative to the well bore and resulting purge volumes and times. The key is to minimize disturbance of water and solids in the well casing.

F. Filtration

Decisions to filter samples should be dictated by sampling objectives rather than as a *fix* for poor sampling practices, and field-filtering of certain constituents should not be the default. Consideration should be given as to what the application of field-filtration is trying to accomplish. For assessment of truly dissolved (as opposed to operationally *dissolved* [i.e., samples filtered with 0.45 µm filters]) concentrations of major ions and trace metals, 0.1 µm filters are recommended although 0.45 µm filters are normally used for most regulatory programs. Alkalinity samples must also be filtered if significant particulate calcium carbonate is suspected, since this material is likely to impact alkalinity titration results (although filtration itself may alter the CO_2 composition of the sample and, therefore, affect the results).

Although filtration may be appropriate, filtration of a sample may cause a number of unintended changes to occur (e.g. oxidation, aeration) possibly leading to filtration-induced artifacts during sample analysis and uncertainty in the results. Some of these unintended changes may be unavoidable but the factors leading to them must be recognized. Deleterious effects can be minimized by consistent application of certain filtration guidelines. Guidelines should address selection of filter type, media, pore size, etc. in order to identify and minimize potential sources of uncertainty when filtering samples.

In-line filtration is recommended because it provides better consistency through less sample handling, and minimizes sample exposure to the atmosphere. In-line filters are available in both disposable (barrel filters) and non-disposable (in-line filter holder, flat membrane filters) formats and various filter pore sizes (0.1-5.0 µm). Disposable filter cartridges have the advantage of greater sediment handling capacity when compared to traditional membrane filters. Filters must be pre-rinsed following manufacturer's recommendations. If there are no recommendations for rinsing, pass through a minimum of 1 L of ground water following purging and prior to sampling. Once filtration has begun, a filter cake may develop as particles larger than the pore size accumulate on the filter membrane. The result is that the effective pore diameter of the membrane is reduced and particles smaller than the stated pore size are excluded from the filtrate. Possible corrective measures include prefiltering (with larger pore size filters), minimizing particle loads to begin with, and reducing sample volume.

G. Monitoring of Water Level and Water Quality Indicator Parameters

Check water level periodically to monitor drawdown in the well as a guide to flow rate adjustment. The goal is minimal drawdown (<0.1 m) during purging. This goal may be difficult to achieve under some circumstances due to geologic heterogeneities within the screened interval, and may require adjustment based on site-specific conditions and personal experience. In-line water quality indicator parameters should be continuously monitored during purging. The water quality

indicator parameters monitored can include pH, redox potential, conductivity, dissolved oxygen (DO) and turbidity. The last three parameters are often most sensitive. Pumping rate, drawdown, and the time or volume required to obtain stabilization of parameter readings can be used as a future guide to purge the well. Measurements should be taken every three to five minutes if the above suggested rates are used. Stabilization is achieved after all parameters have stabilized for three successive readings. In lieu of measuring all five parameters, a minimum subset would include pH, conductivity, and turbidity or DO. Three successive readings should be within ± 0.1 for pH, ± 3% for conductivity, ± 10 mv for redox potential, and ± 10% for turbidity and DO. Stabilized purge indicator parameter trends are generally obvious and follow either an exponential or asymptotic change to stable values during purging. Dissolved oxygen and turbidity usually require the longest time for stabilization. The above stabilization guidelines are provided for rough estimates based on experience.

H. Sampling, Sample Containers, Preservation and Decontamination

Upon parameter stabilization, sampling can be initiated. If an in-line device is used to monitor water quality parameters, it should be disconnected or bypassed during sample collection. Sampling flow rate may remain at established purge rate or may be adjusted slightly to minimize aeration, bubble formation, turbulent filling of sample bottles, or loss of volatiles due to extended residence time in tubing. Typically, flow rates less than 0.5 L/min are appropriate. The same device should be used for sampling as was used for purging. Sampling should occur in a progression from least to most contaminated well, if this is known. Generally, volatile (e.g., solvents and fuel constituents) and gas sensitive (e.g., Fe^{2+}, CH_4, H_2S/HS^-, alkalinity) parameters should be sampled first. The sequence in which samples for most inorganic parameters are collected is immaterial unless filtered (dissolved) samples are desired. Filtering should be done last and in-line filters should be used as discussed above. During both well purging and sampling, proper protective clothing and equipment must be used based upon the type and level of contaminants present.

The appropriate sample container will be prepared in advance of actual sample collection for the analytes of interest and include sample preservative where necessary. Water samples should be collected directly into this container from the pump tubing.

Immediately after a sample bottle has been filled, it must be preserved as specified in the site (QAPP). Sample preservation requirements are based on the analyses being performed (use site QAPP, FSP, RCRA guidance document [U. S. EPA, 1992] or EPA SW-846 [U. S. EPA, 1982]). It may be advisable to add preservatives to sample bottles in a controlled setting prior to entering the field in order to reduce the chances of improperly preserving sample bottles or introducing field contaminants into a sample bottle while adding the preservatives.

The preservatives should be transferred from the chemical bottle to the sample container using a disposable polyethylene pipet and the disposable pipet should be used only once and then discarded.

After a sample container has been filled with ground water, a Teflon™ (or tin)-lined cap is screwed on tightly to prevent the container from leaking. A sample label is filled out as specified in the FSP. The samples should be stored inverted at 4°C.

Specific decontamination protocols for sampling devices are dependent to some extent on the type of device used and the type of contaminants encountered. Refer to the site QAPP and FSP for specific requirements.

I. Blanks

The following blanks should be collected:

(1) field blank: one field blank should be collected from each source water (distilled/deionized water) used for sampling equipment decontamination or for assisting well development procedures.

(2) equipment blank: one equipment blank should be taken prior to the commencement of field work, from each set of sampling equipment to be used for that day. Refer to site QAPP or FSP for specific requirements.

(3) trip blank: a trip blank is required to accompany each volatile sample shipment. These blanks are prepared in the laboratory by filling a 40-mL volatile organic analysis (VOA) bottle with distilled/deionized water.

V. Low-Permeability Formations and Fractured Rock

The overall sampling program goals or sampling objectives will drive how the sampling points are located, installed, and choice of sampling device. Likewise, site-specific hydrogeologic factors will affect these decisions. Sites with very low permeability formations or fractures causing discrete flow channels may require a unique monitoring approach. Unlike water supply wells, wells installed for ground-water quality assessment and restoration programs are often installed in low water-yielding settings (e.g., clays, silts). Alternative types of sampling points and sampling methods are often needed in these types of environments, because low-permeability settings may require extremely low-flow purging (<0.1 L/min) and may be technology-limited. Where devices are not readily available to pump at such low flow rates, the primary consideration is to avoid dewatering of

the well screen. This may require repeated recovery of the water during purging while leaving the pump in place within the well screen.

Use of low-flow techniques may be impractical in these settings, depending upon the water recharge rates. The sampler and the end-user of data collected from such wells need to understand the limitations of the data collected; i.e., a strong potential for underestimation of actual contaminant concentrations for volatile organics, potential false negatives for filtered metals and potential false positives for unfiltered metals. It is suggested that comparisons be made between samples recovered using low-flow purging techniques and samples recovered using passive sampling techniques (i.e., two sets of samples). Passive sample collection would essentially entail acquisition of the sample with no or very little purging using a dedicated sampling system installed within the screened interval or a passive sample collection device.

A. Low-Permeability Formations (<0.1 L/min recharge)

1. Low-Flow Purging and Sampling with Pumps

a. "portable or non-dedicated mode" - Lower the pump (one capable of pumping at <0.1 L/min) to mid-screen or slightly above and set in place for minimum of 48 hours (to lessen purge volume requirements). After 48 hours, use procedures listed in Part IV above regarding monitoring water quality parameters for stabilization, etc., but do not dewater the screen. If excessive drawdown and slow recovery is a problem, then alternate approaches such as those listed below may be better.

b. "dedicated mode" - Set the pump as above at least a week prior to sampling; that is, operate in a dedicated pump mode. With this approach significant reductions in purge volume should be realized. Water quality parameters should stabilize quite rapidly due to less disturbance of the sampling zone.

2. Passive Sample Collection

Passive sampling collection requires insertion of the device into the screened interval for a sufficient time period to allow flow and sample equilibration before extraction for analysis. Conceptually, the extraction of water from low yielding formations seems more akin to the collection of water from the unsaturated zone and passive sampling techniques may be more appropriate in terms of obtaining "representative" samples. Satisfying usual sample volume requirements is typically a problem with this approach and some latitude will be needed on the part of regulatory entities to achieve sampling objectives.

B. Fractured Rock

In fractured rock formations, a low-flow to zero purging approach using pumps in conjunction with packers to isolate the sampling zone in the borehole is suggested. Passive multi-layer sampling devices may also provide the most "representative" samples. It is imperative in these settings to identify flow paths or water-producing fractures prior to sampling using tools such as borehole flowmeters and/or other geophysical tools.

After identification of water-bearing fractures, install packer(s) and pump assembly for sample collection using low-flow sampling in "dedicated mode" or use a passive sampling device which can isolate the identified water-bearing fractures.

VI. Documentation

The usual practices for documenting the sampling event should be used for low-flow purging and sampling techniques. This should include, at a minimum: information on the conduct of purging operations (flow-rate, drawdown, water-quality parameter values, volumes extracted and times for measurements), field instrument calibration data, water sampling forms and chain of custody forms. See Figures 2 and 3 and "Ground Water Sampling Workshop -- A Workshop Summary" (U. S. EPA, 1995) for example forms and other documentation suggestions and information. This information coupled with laboratory analytical data and validation data are needed to judge the "useability" of the sampling data.

VII. Notice

The U.S. Environmental Protection Agency through its Office of Research and Development funded and managed the research described herein as part of its in-house research program and under Contract No. 68-C4-0031 to Dynamac Corporation. It has been subjected to the Agency's peer and administrative review and has been approved for publication as an EPA document. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

The Low-Down on Low Flow

By: Greg Giles and Jeff Story
Bureau of Ground Water Pollution Abatement

In recent years there has been much discussion of alternative purging and sampling methods in the technical literature, particularly where low flow rates are used. These methods have been termed low-flow, low-stress, minimum-drawdown and micropurging, among others. These terms usually refer to the use of very low ground water extraction rates (pumping rates below 1 liter/minute) during well purging and sampling. Since this method is not addressed in the Department's Field Sampling Procedures Manual (1), this article has been written to discuss this procedure so that people who write and review low-flow sampling plans will be better able to assess when the use of this procedure is appropriate.

History and Significance

Regulators and the regulated community have been at odds over the issue of filtering water samples collected for metals analysis. The regulated community has argued that the incorporation of aquifer matrix material (i.e., silt & clay) into ground water samples result in the generation of ground water metals data that are biased high. Metals are naturally occurring and exist in all subsurface geologic material; the required acid preservation of water samples may release metals previously bound to the surface of aquifer material included in the water sample or dissolve some aquifer material altogether (e.g., metal oxides & hydroxides). Therefore, it is reasonable to assume that the incorporation of aquifer matrix material into water samples, which increases turbidity of the water samples, will result in higher metals concentrations.

The cause(s) of turbidity in a given ground water sample may be from any or all of the following:

1. Natural turbidity (i.e., mobile colloids) in the aquifer;
2. The well may have been improperly constructed.
   Considering the nature of the aquifer material the well is installed in, the screen slot size chosen for the well may be too large or the sandpack placed in the annular space around the well screen may be too coarse;
3. The well may have been improperly or inadequately developed;
4. The well may have been pumped at too high a flow rate during the purging or

sampling of the well. Anytime that a well is pumped at a rate that is higher than the well's recharge rate, or higher than the rate at which the well was previously developed at, sediment may be stirred up within the well casing or released from the aquifer into the well, resulting in the water becoming turbid; and,

5. The procedures used during well sampling may result in increased well turbidity. The sounding of wells with probes to determine total well depth may stir up sediment that has accumulated at the bottom of the well. The sediment will be pulled up the water column as the probe is reeled up to the surface. The contact of sampling equipment with the well casing or well screen may release material into the well, and the quick movement of sampling equipment within the well (e.g., bailers) may produce turbidity due to hydrostatic stresses between the well and the surrounding aquifer.

A 0.45-micron filter is the industry standard to filter water samples. Puls and Barcelona (2) concluded that the use of a 0.45-micron filter was not useful, appropriate or reproducible in providing information on metals mobility in ground water systems, nor was it appropriate for the determination of truly dissolved constituents in ground water. The argument that well samples should not be filtered for metals analyses is also supported by the Department's Field Sampling Procedures Manual (1) which states (on page 178) that the Department requires "metals analysis to be performed on **unfiltered** ground water samples pursuant to the requirements of the Safe Drinking Water Act and the Clean Water Act."

With the requirement that water samples analyzed for metals not be filtered, the technique of low-flow purging/ sampling appears to have originated as a means of reducing turbidity in ground water samples. As stated in the April 1996 EPA Ground Water Issue (3), "Sampling-induced turbidity problems can often be mitigated by using low-flow purging and sampling techniques."

While the principal goal of the low-flow sampling technique is the collection of representative ground water samples, one of the major benefits of this technique is the potential cost savings due to the generation of less purge water requiring storage, transportation and disposal. The Department has received an increasing number of requests to allow low-flow sampling, and the potential reduction in the amount of purge water generated appears to be largely responsible for the increase in such requests.

Low-Flow Procedures

The underlying principle of the low-flow technique is that at low pumping rates (less than 1 liter/minute with 0.1 to 0.5 liter/minute being typical), the ground water flow in the area of the sampling device intake approaches horizon-tal linearity (i.e., the ground water that is being drawn into the sampling device should be limited to the sandpack and aquifer in the immediate area of the sampling device intake). According to the EPA document (3) on page 5, low-flow "refers to the velocity with which water enters the pump intake and is imparted to the formation pore water in the immediate vicinity of the well screen....The objective is to pump at a rate that minimizes stress (drawdown) to the extent practical."

Where there is no (or minimal) drawdown during purging and sampling the well is recharged by the aquifer at the same rate the well is being pumped. Under low-flow sampling conditions, suspended solids (e.g., colloids) are considered to be mobile in the aquifer, representative of natural conditions, and not an artifact of sampling or well construction. For this reason, analytical results for metals testing using low-flow sampling are considered to be representative of the total mobile contaminant load in the aquifer (4). Thus, sampling for both "total" and "dissolved" metals is usually not needed.

Using the low-flow sampling technique, wells are purged and sampled at flow rates at or below 1 liter/minute. There is generally no required volume of water to purge from the well before collecting the ground water sample. Instead, the decision on when the ground water sample can be collected is based on the stabilization of ground water-quality parameters (e.g., temperature, pH, Eh, specific conductance, dissolved oxygen (DO) and turbidity). Accordingly, it is important that the stabilization parameters be measured accurately, and that the purging be conducted in such a manner that the sampling procedure does not affect the field parameter values (e.g., some submersible pumps generate a lot of heat when pumping at very low rates; this may cause the temperature reading to drift); sampling devices that operate under negative pressure (e.g., peristaltic pumps) cause degassing of the water which may cause drift in the pH and dissolved oxygen readings.

During conventional purging and sampling the sample can often represent an average of the entire screened interval/bedrock borehole. In contrast, low-flow sampling conceptually results in the collection of a sample drawn from a discrete interval in the well. As such, the collection of a ground water sample using low-flow techniques may be considered somewhat analogous to collecting discrete ground water samples using equipment such as "Geoprobe" and "Hydropunch" samplers and temporary well points which typically have short intakes.

Advantages

1. With respect to metals analysis, low-flow samples are typically considered to be representative of the total mobile contaminant load (i.e., dissolved and colloid-associated). This reduces the need for sample filtration. Samples collected using low-flow methods usually contain less turbidity.

2. Using low-flow procedures, the volume of water purged from the well may be significantly reduced. Costs associated with the storage, transport and disposal of the purge water may be reduced and the amount of time needed to purge the well may be reduced.

3. Because the same equipment is used for well purging and well sampling, less equipment may need to be used in the field.

4. Because the low-flow technique generates water samples obtained from very discrete zones, if the contaminant distribution in the section of the aquifer screened by the well is heterogeneous, the sample collected by low-flow procedures may show signifi-cantly higher contaminant concentrations than samples collected at higher flow rates (i.e., using traditional sampling methods).

5. The reduction in the amount of fine-grained material flowing into the well can increase well life and reduce the need for well re-development.

Disadvantages

1. Not all sampling equipment can be used for low-flow sampling. Pumps used for low-flow sampling should be variable in speed and designed to operate at very low pumping rates. Pumps should preferably operate under positive displacement.

2. Because the measurement of DO and Eh must be made before the ground water comes in contact with the atmosphere, a flow-through cell must be used to measure these parameters in the field.

3. The zone sampled within the well by low-flow methods is conceptually limited. If the contaminant distribution in the screened section of the aquifer is heterogeneous, which may be the case in most wells, the sample results obtained by low-flow sampling may be significantly biased low if the sampling device intake is not placed at the same depth as that of the highest contaminant concentration entering the well. Accordingly, for wells contaminated with DNAPL or LNAPL type contamina-tion, the sampling device intake depth could signifi-cantly affect the sampling results. For wells con-structed with long screens, vertical flow gradients within the well may cause mixing of ground water and the samples will not be depth-discrete.

4. The method requires higher initial capital costs and longer set-up time in the field.

Summary

EPA's issue paper (3) provides a very thorough evaluation of the method and its advantages and disadvan- tages. This paper is considered recommended reading by anyone involved in low-flow sampling.

At this time the Department does not have a formalized low-flow sampling procedure/policy in place. However, the Department is currently working to develop a formalized low-flow sampling guidance document. Currently, low-flow sampling can be approved only on a case-by-case basis until the Department develops appropriate guidance. A low-flow sampling plan must be provided to the Department for review and approval. Low-flow sampling plans should be as detailed as possible and take into consideration well construction, contaminant type and distribution in the aquifer, and local hydrogeology.

Appendix A: Standard Operating Guideline
Field Measurements of an Aqueous Sample Using a Portable Multiple-Parameter Meter

A.1 Introduction

This guideline describes the procedures that will typically be followed by Kennedy/Jenks Consultants personnel during field measurement of aqueous samples for chemistry parameters using a portable multiple-parameter meter in the state of New Jersey. ***This SOG assumes equipment will be rented from a New Jersey-certified laboratory, calibrations will be performed by Kennedy/Jenks personnel each day of use, and calibration records will be kept for each instrument rented and traceable by equipment serial number***. This SOG addresses methodologies for the calibration and analysis of the following water chemistry parameters:

- pH
- conductivity
- temperature
- dissolved oxygen
- turbidity

A.2 Equipment

- Horiba U-52 or U-53
- YSI 6820 or 6920
- LaMotte 2020we
- Laboratory wipes
- Deionized water (DI)
- Calibration solutions
- Glass thermometer with current NIST-certified calibration check documentation
- Sample container or flow through cell

A.3 Rental Equipment Documentation

This SOG assumes equipment will be rented from a New Jersey-certified laboratory. Kennedy/Jenks Consultants personnel should maintain calibration sample and analysis records on laboratory-rented equipment, traceable by instrument serial number, for a minimum of 5 years. The following information should be provided by the rental agency and kept in a central office file:

- Documentation for all prep calibrations performed (traceable by serial number)
- Date received, date opened, and expiration date for standards and solutions used in prep calibrations

- National Institute of Standards and Technology (NIST) certificate and applicable certificate(s) of analysis

- Certificates of analysis for reagents and solutions used to perform prep calibrations.

A.4 Calibration Procedure

The following Sections A.3.1 through A.3.5 present typical procedures for calibration of a Horiba U-52 multiple-parameter meter. Similar calibration steps should be followed for calibration of YSI 6820 or 6920 multiple-parameter meters. Consult the equipment manual, manufacturer, or rental agency for additional information and/or troubleshooting tips.

Readings taken and adjustments made during calibration and calibration checks should be recorded on standardized calibrations logs or in a bound field log book. Calibration logs should include the analyst's initials, date and time when calibration was completed, serial number(s) of meter(s), and lot numbers and expiration dates for calibration solutions.

A.4.1 pH

Prior to beginning calibration, clean the probe thoroughly with DI and pat dry with a clean towel.

With the power on press the unit's CAL key to set the calibration mode. Press the down arrow key to move the cursor to Manual Calibration, then press the ENTER key.

1. Move the cursor to pH, then press ENTER.

2. Set the number of calibration points then press ENTER. For multiple-parameter meters, a minimum of two point calibration will be conducted.

3. Fill the calibration cup with pH 4 buffer solution and place the probe into the cup. Allow to stand until a constant reading is observed. Record the pH reading and temperature displayed on the screen.

4. Press the UP/DOWN keys to set the value of the pH buffer (based on buffer value at the temperature of the buffer). See attached table for buffer values based on temperature.

5. Press ENTER to start the zero calibration. When the message "Cal complete. Press ENT to Span cal" appears – press ENTER. Buffered calibration values should be within ±0.05 pH units of the true value and recorded to 2 decimal places.

6. Remove the probe from the calibration cup and rinse it with DI water.

7. Fill the calibration cup with pH 10 buffer solution and place the probe into the cup. Allow to stand until a constant reading is observed. Record the pH reading and temperature displayed on the screen.

8. Press the UP/Down keys to set the value to the buffer value of pH buffer (based on buffer value at the temperature of the buffer). Press the ENTER key to start span calibration.

Buffered calibration values should be within ±0.05 pH units of the true value and recorded to 2 decimal places.

9. When the message “Cal complete. Press ENT to Span cal” appears – press ENTER.

10. Remove the probe from the calibration cup and rinse it with DI water.

11. Repeat Steps 3 through 9 for pH 7 solution if a three-point calibration is available.

12. When the message “Cal complete. Press ENT to Span cal” appears – press ENTER. Calibration is set and the unit returns to the manual cal screen.

Calibration Check

Calibration checks should be performed on the mid-point standard immediately after calibration is completed with an acceptance criterion of ±0.10 pH units of the true value (based on the buffer value at the temperature of the buffer). A calibration check should be performed once every three hours when the meter is in use longer than three hours after initial calibration.

1. Clean the probe thoroughly with DI water and pat dry with a clean towel.
2. Fill the calibration cup pH buffer solution 7 and place the probe into the cup. Allow to stand until a constant reading is observed. Record the pH reading and temperature displayed on the screen. Do NOT adjust the instrument.
3. Clean the probe thoroughly with DI water and pat dry with a clean towel.

If the three hour calibration check values are not within ±0.20 pH units of the pH buffered solution (compensating for temperature), and further pH measurements will be collected within the next three hours, recalibrate the meter followed by another standard check.

All solutions used for calibration will be discarded after each use.

A.4.2 Conductivity

Prior to beginning calibration, clean the probe thoroughly with DI and pat dry with a clean towel. Conductivity measurements should be recorded in milliSiemens per centimeter (mS/cm).

With the power on press the unit’s CAL key to set the calibration mode. Press the down arrow key to move the cursor to Manual Calibration, then press the ENTER key.

1. Move the cursor to COND.

2. Set the number of calibration points then press ENTER.

3. Use the UP/DOWN keys to set the value to 0.0.

4. Press ENTER to start zero calibration. When the message “Cal complete. Press ENT to Span cal” appears – press ENTER.

5. Use the MODE key to move the cursor to SPAN.

6. Fill the calibration cup with conductivity standard in the 1-10 range and place the probe into the calibration cup.

7. Use the UP/DOWN keys to set the value of the conductivity standard value.

8. Press ENTER to start the span calibration for this conductivity range. When the message "Cal complete. Press ENT to Span cal" appears – press ENTER.

9. Calibration is finished when the message "cal complete. ENT to manual cal menu" appears. Press the ENTER to return to the manual cal screen.

10. Wash the sensor probe 2-3 times with deionized water.

11. Perform a calibration check with a non-zero conductivity standard following calibration, while in measurement mode.

12. If calibration check values are not within ±1.0% conductivity units of the true conductivity value, recalibrate the meter followed by another standard check.

All solutions used for calibration will be discarded after use.

A.4.3 Temperature

The temperature probe on the meter will be calibrated by the rental company prior to use. All documentation associated with the calibration will be retained by Kennedy/Jenks. If there is further need for calibration of the temperature probe, see the following procedure.

Equipment used should be capable of measuring temperature in *at least* 0.50°C increments (the Horiba U-52 is capable of measuring temperature in 0.01°C increments).

With the power on press the unit's CAL key to set the calibration mode. Press the down arrow key to move the cursor to Manual Calibration, then press the ENTER key.

1. Fill a container with water. Submerge the sensor probe and a certified thermometer into the water.

2. If the temperature readings are within 0.50°C of each other no further calibration is required. If the temperature readings are greater than 0.50°C of each other proceed to step 3.

3. Move the up and down keys to set the calibration value to the temperature indicated on the certified thermometer.

4. Allow the measurement value on the meter to stabilized then press ENTER to start the calibration.

5. Calibration is finished when the message "Cal complete. CNT to measure." appears.

Each field meter will be tested against a NIST-certified thermometer. The NIST-certified thermometer will be graduated in at least 0.20°C increments.

A.4.4 Dissolved Oxygen

With the power on press the unit's CAL key to set the calibration mode. Press the down arrow key to move the cursor to Manual Calibration, then press the ENTER key.

1. Move the cursor to DO or % DO then press the ENTER key.

2. Set the number of calibration points then press the ENTER key.

3. Rinse the probe 2-3 times with deionized water then allow the probe to read against air or submerge the probe in air saturated water for a single point calibration.

4. When the message "Cal complete. Press ENT to Span cal" appears – press ENTER to set the zero value and start the span calibration for a two-point calibration.

5. Submerge the probe in the zero-oxygen standard solution (do not use the cal cup for DO calibration). Press the up and down keys to set the DO value to 0.00 mg/L and press ENT.

6. When the message "Cal complete. Press ENT to Span cal" appears – press ENTER to set the zero value and start the span calibration.

7. Remove the probe from the zero standard and rinse it with DI water

8. Calibration is finished when the message "cal complete. ENT to manual cal menu" appears. Press the ENTER to return to the manual cal screen.

9. Following calibration perform a calibration check with the zero-oxygen standard solution while in measurement mode.

10. If calibration check values are not within < 0.3 mg/L of the true value, recalibrate the meter followed by another standard check.

A.4.5 Turbidity on a multi-parameter meter

With the power on press the unit's CAL key to set the calibration mode. Press the down arrow key to move the cursor to Manual Calibration, then press the ENTER key.

1. Move the cursor to TURB then press the ENTER key. Fill the calibration cup with 0.0 NTU standard and place the cleaned probe into the calibration cup.

2. Press the up and down keys to set the reading to 0.0 then press ENTER to start the zero calibration. When the message "Cal complete. Press ENT to Span cal" appears – press ENTER to set the zero value and start the span calibration.

3. Remove the probe from the calibration cup and rinse it with DI water.

4. Fill the calibration cup with a second NTU standard.

5. Use the up and down keys to set the reading to the value of the calibration standard. Press ENTER to start the span calibration for this turbidity range.

6. Calibration is finished when the message “cal complete. ENT to manual cal menu” appears. Press the ENTER to return to the manual cal screen.

7. Following calibration perform a calibration check with a non-zero turbidity standard solution while in measurement mode.

8. If calibration check values are not within ±10.0% NTU of the true value, recalibrate the meter followed by another standard check

All solutions used for calibration will be discarded after use.

A.4.6 Turbidity on a stand-alone meter

With the power on press the unit’s MEASURE key to set the calibration mode. Press the down arrow key to move the cursor to Turbidity- With Blank, then press the ENTER key.

1. Rinse a clean tube three times with the blank (0.0 NTU Standard) and fill the tube to the fill line with the blank down the inside of the tube to avoid bubbles. Wipe the tube with a lint free cloth. Insert the tube in the meter and align the index line on the tube with the index arrow on the meter and close the lid.

2. Press ENTER to scan the blank. The screen will display Blank Done and then return to the Turbidity-With Blank Menu.

3. Rinse a clean tube or the same tube three times with the standard (a non-zero NTU) following the same instructions as Step 1. Press ENTER and once the screen displays a reading move the cursor to Calibrate and press ENTER.

4. Scroll up or down to the concentration of the standard and press ENTER. Press ENTER to Set Calibration. The meter is now ready to read a sample.

5. Following calibration perform a calibration check with a non-zero turbidity standard solution while in measurement mode.

6. If calibration check values are not within ±10.0% NTU of the true value, recalibrate the meter followed by another standard check

All solutions used for calibration will be discarded after use.

A.5 Measurement Procedure

Using a Sample Container

Place the sample in a clean straight sided polyethylene or glass container using a sufficient amount of sample to submerge the probe.

1. Rinse the probe with DI water to make sure it is clean.

2. Place the probe into the sample and gently agitate/stir the sample.

3. Use the SELECT Key to move the upper cursor to view each parameter

4. Allow the readings to stabilize, and then record each parameter reading indicated on the instrument display.

Using a Flow-Through Cell

1. Sample is analyzed in a flow through cell during low flow purging and sampling activity.

2. Rinse the probe with DI water to make sure it is clean.

3. Sample is mixed inside the flow through cell through continuous movement of source water through the flow through cell by means of a sampling pump.

4. Use the SELECT Key to move the upper cursor to view each parameter

5. Allow the readings to stabilize, and then record each parameter reading indicated on the instrument display.

Note: Proficiency testing (PT) samples should be measured and recorded as routine environmental samples on standardized calibration logs or bound field log book. If a standalone turbidity meter is used for PT samples it should be used occasionally for regular sample analysis throughout the PT cycle.

A.6 Data Management

All calibration and measurement data will be documented on standardized calibration logs and filed in the associated project file.

A.7 Waste Management

Disposal of calibration solutions will follow manufacturer instructions.

A.8 Quality Control

All samples are to be analyzed immediately (within 15 minutes of collection).

Section 1: Introduction

On behalf of Hercules LLC (Hercules), Kennedy Jenks Consultants, Inc. (KJ) prepared this *TNT Project Area Soil Reuse Plan* (Soil Reuse Plan) outlining the approach for the characterization and placement of clean and alternative fill material at the Hercules Kenvil Works Facility located in Kenvil, Morris County, New Jersey (the Facility; **Figure 1**). This Soil Reuse Plan supports the *TNT Project Area Soil Remedial Action Work Plan* (TNT RAWP) for the 2,4,6-trinitrotoluene (TNT) Project Area (TNT Project Area; Area of Concern), an approximately 80-acre area in the southwestern portion of the Facility (**Figure 2**).

The TNT RAWP outlines a remedy that employs physical soil processing and bioremediation in constructed treatment cells (bio cells) onsite to break down energetic source material present in TNT Project Area soil, and reuse of treated material from the bio cells as backfill in source area excavations. Section 2.3 provides additional details regarding the remedy.

1.1 Purpose and Objectives

This Soil Reuse Plan was prepared in accordance with the New Jersey Department of Environmental Protection's (NJDEP's) *Fill Material Guidance for SRP Sites* (Fill Material Guidance*)* to facilitate the import and placement of clean fill and reuse of treated material as alternative fill within the TNT Project Area to support remedial objectives and remain protective of human health and the environment. Specifically, the Soil Reuse Plan outlined herein:

- Evaluates use of alternative fill and imported clean fill within the context of the NJDEP Fill Material Guidance
- Outlines a plan to track placement of alternative fill material being treated in biocells and oversize material washed and segregated by the soil processing plant
- Presents reporting requirements and schedule

1.2 Organization

The remainder of this Soil Reuse Plan is organized as follows:

- Section 2, *Background*, provides a brief overview of the TNT Project Area history, physical setting and remedy.
- Section 3, *Clean Fill Requirements*, identifies the procedures required to support the use of offsite donor material.
- Section 4, *Alternative Fill Evaluation*, presents the proposed use of treated onsite source material and assesses compliance with NJDEP Fill Material Guidance.
- Section 5, *Tracking and Record Keeping*, outlines supporting documentation required for alternative and clean fill use.

Section 2: Background

2.1 Facility Description

The Facility occupies 1,059 acres along the Route 80 corridor and is located approximately 0.5 miles northwest of the center of Kenvil, in Morris County, New Jersey. Regionally, the Facility is approximately 40 miles west of New York City and 30 miles east of the Delaware Water Gap. The Facility is located in the New Jersey Highlands physiographic province of north-central New Jersey amidst the characteristic broad, elevated ridges separated by long, narrow valleys. The Facility is situated on a valley floor between two forested ridgelines oriented in a southwest to northeast direction. Beyond these forested ridgelines, the Facility is flanked by transit routes (I-80, New Jersey Transit railroad), state and county roads (Route 46, Berkshire Valley Road, Howard Boulevard), and a mixture of commercial and residential development.

The Facility began operation in 1871, initially manufacturing dynamite to support the regional iron ore mining industry. The Facility was operated by various companies until 1912, when Hercules became the sole owner. Throughout its history, the Facility manufactured propellants and explosive and energetic (E&E) constituents such as TNT, nitroglycerin (NG), pentaerythritol tetranitrate (PETN), smokeless powder, ammonium nitrate fuel oil (ANFO), and various specialty products (e.g., initiating materials, ingredients for medical applications, and materials for actuating devices) for military and commercial applications. Through the latter years of Facility operation, production focused mainly on smokeless powders. Alliant Tech Systems produced smokeless powder under a Facility lease agreement from 1995 to 1996. The Facility ceased operation in December 1996, and Hercules re-acquired control of the Facility on January 1, 1997.

2.2 TNT Project Area

The Facility produced TNT from 1917 until 1919, after which time the production structures remained dormant until demolition in the early 1970s. Site investigation and remedial investigation (SI/RI) activities identified TNT, intermediary manufacturing products (2,4-dinitrotoluene [2,4-DNT], 2,6-dinitrotoluene [2,6-DNT]) and degradation byproducts (2-amino-4,6-DNT [2ADNT], and 4-amino-2,6-DNT [4ADNT]) [1] in soil and groundwater within areas that historically supported TNT manufacturing.

Processing and movement of raw materials, intermediaries, and finished product through the TNT manufacturing line provided opportunities for the release of manufacturing-related constituents[2] to Facility soil, as did process upsets (e.g., fires, explosions). At room temperature, both TNT and DNT finished product occur as crystalline solids. When released to the ground during manufacturing process upsets, these materials were in a heated liquid form and capable of migrating short distances in soil before solidifying. Subsequent distribution, migration, and degradation has occurred over the last century, resulting in the presence of target constituents in soil and groundwater underlying the TNT Project Area. The presence of ADNTs[3] provides an

[1] For the purpose of the TNT RAWP and this Soil Reuse Plan, TNT, 2,4-DNT, 2,6-DNT, 2ADNT and 4ADNT are collectively referred to as “target constituents”.

[2] Target constituents represent the primary manufacturing-related constituents in the TNT Project Area. Lead-lined process vessels and piping were used in the TNT manufacturing process, and lead represents a secondary manufacturing-related constituent on the TNT Project Area.

[3] Collective term that includes 2-ADNT and 4-ADNT

indication that microbial (biological) degradation of TNT is naturally occurring in Facility soil and groundwater.

Consistent with the approach developed through the SI/RI process, this Soil Reuse Plan defines the area of concern (AOC) as a contiguous geographic area with common constituents of concern attributable to a discrete historical operation at the Facility. Specifically, the AOC is the TNT Project Area (**Figure 2**). This AOC contains the former TNT manufacturing line (38 unique structures) and associated drying, finishing, packing, and storage structures that supported TNT manufacturing operations.

The proposed remedy for this AOC achieves remedial action objectives for a contiguous geographic area with common constituents of concern attributable to a discrete historical operation at the Facility. For the purposes of administrative tracking, the TNT Project Area contains the former TNT operational area (AOC-11) and portions of the Dynamite (AOC-5), NG (AOC-9), and PETN (AOC-13) operational areas (as identified in the Case Inventory Document [CID] presented as Appendix I in Volume A of the Phase II Remedial Investigation Report [Phase II RIR] [Hercules, 2016]), and 108 unique features identified as individual AOCs during the SI (as identified in the AOC Tracking Table presented as Appendix H in Volume A of the Phase II RIR).

2.2.1 Geology & Hydrogeology

The TNT Project Area occupies approximately 80 acres that spans the eastern slope and terminus of the western ridge and a portion of the adjacent valley floor. Ground surface elevations range from 720 to 800 feet above mean sea level.

Soil types vary between the ridge and valley. Ridge soils are comprised of colluvium and weathered bedrock while valley floor soils are predominantly sand and gravel, with minimal to moderate silt and clay. Bedrock underlies the ridge at depths ranging from 10 to 50 feet, and dips to approximately 200 feet below ground surface (ft bgs) in the valley.

The unconfined upper valley fill aquifer underlies the TNT Project Area. Water table elevations generally follow ground surface topography, with depth to water on the ridge averaging 20 ft bgs tapering to within a few feet of ground surface on the valley floor.

2.2.2 Ecology & Land Use

Former operational structures have been demolished in the TNT Project Area. The area currently exists as vacant land in various states of vegetative succession, primarily grass field and shrublands, interspersed with remnant building remains (e.g., concrete rubble piles) and ground surface infrastructure (e.g., unimproved roads, drainage ditches).

The upper slope of the western ridge immediately west of the TNT Project Area is a mature hardwood forest with sparse understory, and formerly functioned as a buffer between the Facility and surrounding community. Howard Boulevard, commercial development, and an undeveloped steep, terraced ridge occur immediately west of the TNT Project Area. An expansive wetland mosaic punctuated with upland areas constructed to support former operational structures or transportation corridors (railbeds and roads) lies to the east of the TNT Project Area.

2.3 Project Description

The SI/RI characterized and delineated the nature and extent of Facility-related influences in the TNT Project Area, and identified the need for active remediation. A series of focused studies were conducted to select and design the remedy for the TNT Project Area, and refine the SI/RI delineation of TNT source mass in soil. The selected multi-phase remedy relies on soil processing and bioremediation to achieve remedial objectives.

2.3.1 Target Constituents of Concern

Remedial objectives will be achieved for target constituents within the TNT Project Area and a subset of secondary constituents retained as constituents of concern (COCs).

Target constituents include:

- TNT
- 2,6-DNT
- 4-ADNT
- 2,4-DNT
- 2-ADNT

The proposed remedy addresses the presence of target constituents (including crystalline solid TNT particles) in soil via a multi-phase process focused on degrading source mass in soil.

2.3.2 Remedy Overview

The initial phase of the proposed remedy involves physical processes beginning with the serial excavation of soil containing target constituent source mass from 16 delineated areas. Excavation areas are shown on **Figure 3**. The TNT Project Area Excavation, Blending, and Staging Plan (EBS Plan) identifies an excavation sequence and soil blending program that achieves a target TNT concentration of 2,000 milligrams per kilogram (mg/kg) in feed material going into the soil processing plant. The soil processing plant, using industry-standard mining and aggregate management processes and equipment, physically segregates native aggregate and reduces TNT particle grain size to increase the surface area to volume ratio of crystalline solids in the blended soil. Ultimately, the processing plant produces three process streams:

- Biofeed - particle sizes less than 2 millimeters (mm) in diameter, including target constituent source mass
- Coarse Oversize - 12.7mm to 50.8mm larger native aggregate free of crystalline TNT solids
- Fine Oversize - 2mm to 12.7mm oversize native aggregate free of crystalline TNT solids

The second phase of the proposed remedy involves enhanced ex-situ bioremediation of biofeed in a controlled monitored environment. Biofeed from the soil processing plant will be amended with DARAMEND OE®, slurried at approximately 20 percent solids, then pumped into the biocells. The amended biofeed slurry will gravity dewater in the biocells. Monitoring and management of the amended biofeed will be performed over the course of treatment to quantify the degradation of target constituents and maintain soil conditions amenable for biological breakdown.

Following a 10- to 12-month treatment cycle within the bio cells, the final phase of the proposed remedy includes the placement of the treated biofeed in the source excavation areas as

alternative fill where in-situ biodegradation will continue to address residual target constituent mass. DARAMEND OE® continues to support natural biodegradation for approximately 5 years, after which natural attenuation by native microbial communities will continue and serve as the final remedy for soil and groundwater.

This three-phase remedy of soil preparation, ex-situ enhanced bioremediation, and in-situ biodegradation will occur on an annual schedule over an estimated five cycles (or years) to process approximately 65,000 cy of material. Treated material will be re-used onsite as backfill in TNT Project Area excavations (i.e., alternative fill).

The TNT Project Area Soil Remediation – Process Confirmation Plan (PCSP), Appendix D of the TNT RAWP, provides a sampling program to document the continued decrease in target constituent concentrations in soil undergoing treatment in the bio cells, characterize processed (oversize) and treated material to facilitate reuse as backfill in TNT Project Area, and quantify residual target constituent mass in treated soil that will be used to backfill excavations where it will undergo additional biological degradation.

2.3.3 Secondary Constituents of Concern

A compliance evaluation conducted as part of the TNT RAWP identified the following secondary constituents as COCs:

- *E&E:* nitroglycerin, 1,3-dinitrobenzene, and nitrobenzene
- *Metals:* arsenic, copper, lead, mercury, and nickel

Secondary E&E constituents comingled with target constituents will be addressed via the proposed remedy. Portions of excavation areas containing metals at concentrations exceeding their NJDEP NRDCSRS will be segregated during processing and treatment, and returned to the excavation from which they were removed. Process confirmation and long-term monitoring sampling will assess the distribution of secondary COC metals following processing, and during both ex-situ and in-situ treatment. The need for additional remedial activities for metals COCs will be addressed once excavations are backfilled prior to initiating site restoration activities. The *TNT Project Area Soil Secondary Constituents of Concern Technical Memorandum* (Appendix C of the TNT RAWP) summarizes the compliance evaluation, calculates the extent of each secondary COC within the TNT Project Area, and identifies COCs within and outside of the anticipated excavation areas identified in the TNT RAWP.

2.3.4 Summary of Fill Materials

Treated biofeed will be used as alternative fill in excavation areas, with the exception of a subset of excavation areas that coincide with areas required for plant construction and equipment staging. These excavations (S, T, U, and V on **Figure 3**) will be backfilled with clean imported fill immediately following excavation.

Clean aggregate will also be imported to upgrade access routes and support plant construction.

Concrete rubble stockpiles in and proximate to excavation areas and other laydown/pad areas will be characterized and managed as part of a sitewide concrete characterization effort prior to implementation of the TNT Project Area remedy.

Section 3: Clean Fill

3.1 Clean Fill Uses

An estimated 4,500 cubic yards of clean fill material (soil) will be imported to backfill excavation areas S, T, U & V (**Figure 3**). Clean aggregate will also be imported to upgrade access routes and support plant construction. Types and volume of clean aggregate will be selected during the site civil design process and will comply with the Fill Material Guidance as outlined below. This process will ensure the types and concentrations of constituents and homogeneity in the proposed clean fill is understood prior to being used onsite.

3.2 Clean Fill Sampling

Donor material proposed for use as clean fill will be provided by the selected contractor performing the remedy in the TNT Project Area. Clean fill will meet geotechnical specifications outlined during the site civil design process and preferably include a clean fill certification demonstrating compliance with NJDEP regulations.

In the event that initial or supplemental sampling is required to demonstrate clean fill compliance, Hercules will follow the processed outlined in the Fill Material Guidance, as summarized below. The clean fill source will be evaluated through a review of the source history, operations and sampling and analysis strategy in accordance with the Fill Material Guidance and NJDEP's *Field Sampling Procedures Manual* (FSPM). Clean fill generated via blending of mulched, composted organic materials (e.g., grass clipping or leaves) or peat moss will be sampled following the blending process. Different concerns will be addressed in the evaluation, sampling, and analysis of each source type. Source locations may include in-state and out-of-state sources of potential clean fill.

Table 2 of the Fill Material Guidance (**Attachment 1**) summarizes sampling frequencies necessary to establish the characteristics of a potential clean fill source. In general, the default sampling will be used for a source site with little or no prior data, and the reduced sampling frequency will be used where there has been some prior assessment of the fill source (e.g., site review, prior sampling). Clean fill sources will be analyzed for Target Analyte List (TAL)/Target Compound List (TCL) and Extractable Petroleum Hydrocarbons (EPH). Additional analyses (e.g., pH, total organic carbon) may be conducted to assess geophysical compatibility.

Section 4: Alternative Fill Evaluation

The final phase of the TNT Project Area remedy utilizes in-situ biological degradation to address remaining target constituent concentrations in soil. Following the period of management in the biocells, treated biofeed (i.e., target constituent concentrations less than NRDCSRS) will be removed and used as alternative fill to backfill the source excavation areas. Approximately 53,500 cy of treated biofeed material will be placed as alternative fill. Alternative fill material will comply with the Fill Material Guidance as outlined below. This process will ensure the proposed alternative fill is thoroughly understood as to the types and concentrations of constituents and homogeneity**.**

4.1 AOC Data Evaluation

The TNT Project Area serves as both the donor and receiving AOC. Excavated material from the TNT Project Area (donor AOC) will be used as alternative fill following bioremediation in biocells to backfill excavation areas within the TNT Project Area (receiving AOC). The TNT Project Area is delineated and the physical properties, contaminants of concern (COCs) and their concentrations are well characterized.

Macroscale delineation of the TNT Project Area was completed as part of the SI/RI and refined delineation sampling, as outlined in the TRDWP (Hercules 2017), built upon the understanding of nature and extent of target constituents identified by the SI/RI with the purpose of more accurately defining the volume of soil requiring ex-situ treatment to remediate target constituents, and provide additional characterization data to support remedial planning (i.e., excavation planning, material handling, and regulatory compliance). Appendix B of the TNT RAWP presents the results of refined delineation sampling.

The TNT Project Area COCs are assessed as follows:

- *Primary COCs:* target constituents (TNT, 2,4-DNT, 2,6-DNT, 2ADNT, 4ADNT) that the proposed remedy is designed to remediate via biological degradation

- *Secondary/Comingled COCs:* constituents other than target constituents (nitroglycerin, 1,3-dinitrobenzene, nitrobenzene, arsenic, copper, lead, mercury and nickel) that also merit remediation per NJDEP's TRSR and *Technical Guidance for the Attainment of Remediation Standards and Site-Specific Criteria* (Attainment Guidance) (2012).

Ultimately the physical characteristics of the TNT Project Area receiving material will differ from that of the donor material. However, the soil preparation process is critical to the bioremediation remedy and includes physical preparation (grain size reduction, large aggregate removal) of the excavated source material with the single objective of concentrating target constituent source mass in a biologically-accessible form (high surface area to volume ratio) in the biofeed material. The treated biofeed material will be homogenous when placed as backfill into the source material excavation areas. The PCSP (Appendix D of the TNT RAWP) provides a sampling program to document the continued decrease in target constituent concentrations in soil undergoing treatment in the biocells and characterize processed (oversize) and treated material to facilitate use as backfill in TNT Project Area excavations. Excavation areas will be backfilled to grade with

a fluff factor to account for settling. Oversize materials (aggregate greater 2mm in diameter) will be sampled and analyzed to demonstrate the effectiveness of the washing procedure at removing soil containing target constituents that may be adhered to the aggregate. Once confirmed clean (i.e., COC concentrations less than NJDEP NRDCSRS), stockpiled material will be moved to a designated area (to be identified during site civil design) and staged for reuse.

4.2 Like on Like Evaluation

The TNT Project Area is the donor and receiving AOC and no new constituents in excess of NJDEP soil remediation standards will be placed in the AOC via alternative fill. Soil containing target constituents will be blended and processed to create biofeed. This level of processing allows tracking of soil at the batch level on an annual cycle (e.g., soil from excavation areas A, B, and C were processed in Year 1). The PCSP provides the necessary information to track characterized biofeed returned to excavation areas (e.g., material from Biocell Nos. 1 and 2 were used to backfill excavation area B). This will allow for process confirmation data from each biocell to serve as the baseline for tracking of long-term monitoring of ongoing degradation in-situ.

There are two secondary COCs (lead and arsenic) greater than NJDEP Non-Residential Direct Contact Soil Remediation Standards (NRDCSRS) located within a subset of proposed excavation areas (B, M, G, R) (**Figure 3**). These excavation areas will be managed in a separate biocell or a portion of a biocell by excavation area and placed back into the original excavation area. In addition, a subset of excavation areas (T, U & V) will be backfilled with clean imported fill to support plant construction and equipment staging for the duration of remedial activities within the TNT Project Area.

The tracking described above and concentration reduction inherent to the remedy demonstrate compliance with the like-on-like requirements. Backfilling a subset of excavations with clean fill also reduces the areal extent of the AOC.

4.3 75th Percentile Evaluation

As discussed earlier in Section 4, a subset of the excavation areas will be backfilled with clean fill to support construction of the process plant and associated structures. This approach also reduces the areal extent of the AOC and obviates the need to comply with the 75th percentile requirement per the Fill Material Guidance.

Nevertheless, greater than 95 percent reduction in target constituent mass is expected to occur during the ex-situ bioremediation phase of the remedy, with the remaining residual mass degraded in-situ over the subsequent 5 years. In-situ degradation will be monitored in accordance with a long-term monitoring plan.

The TNT Project Area remedial objectives focus on target constituents. The influences of remedy implementation on secondary COCs are expected to include:

- Concentration reductions to below NJDEP NRDCSRS of E&E secondary COCs via ex-situ bioremediation occurring in excavation areas

- Re-distribution of non-E&E secondary COCs (metals) below NRDCSRS occurring via the excavation, blending, and treatment processes

- Management of lead and arsenic above NRDCSRS in a subset of excavation areas will be managed in separate treatment cells to facilitate placement back in their original excavation areas

- No disturbance to secondary COCs above NRDCSRS in the TNT Project Area beyond excavation areas

Section 5: Tracking and Record Keeping

5.1 Reporting

Hercules will generate data throughout the soil processing and bioremediation components of the project. Annual reports will summarize and interpret data collected over the previous year in the context of remedial progress and attainment of remedial action objectives established in the TNT RAWP. Annual reports will be submitted to the LSRP and NJDEP and serve as the basis for annual project progress update meetings each spring.

Following the completion of ex-situ bioremediation activities (i.e., attainment of the NRDCSRS remedial action objective), Hercules will prepare a Remedial Action Report (RAR). In accordance with the Fill Material Guidance, the RAR will include documentation supporting the use of clean and alternative fill materials onsite.

5.1.1 Alternative Fill Requirements

Alternative Fill documentation will be included in the annual process monitoring reports and will:

- Present field observations and measurement data
- Provide volume and thickness including surveyed elevations of existing grade and top of alternative fill in excavation areas
- Document the decrease in target constituent concentrations over the treatment period in a biocell and identify which portion of the biocell was placed back into an excavation area for long term monitoring
- Present the confirmation sampling results the demonstrate attainment of the success criteria enabling use of the treated biofeed as backfill (i.e., target constituent concentrations less than NJDEP NRDCSRS)
- Document placement of secondary COCs above NRDCSRS (lead and arsenic) in separate treatment cells and constituent concentrations being placed back in the original excavation areas

5.1.2 Clean Fill Requirements

Clean fill documentation will include copies of fully executed bills of lading from the approved donor site for incoming shipments. Documentation will include the volume and thickness (with surveyed elevations of final subgrade and top of clean fill), analytical data demonstrating compliance with N.J.A.C. 7:26E-1.8 definition of clean fill, and documentation of areas where clean fill has been placed.

Hercules – Kenvil Works Listed K Waste Contained In/Out Determination Letter

Dear Mr. Meeks,

The New Jersey Department of Environmental Protection (Department) has completed a review of the RCRA Hazardous Waste Classification Request (dated July 1, 2020), submitted by Hercules LLC pursuant to: The Site Remediation Reform Act (N.J.S.A. 58:10C-1 et seq.), the Administrative Requirements for the Remediation of Contaminated Sites (N.J.A.C. 7:26C), the Technical Requirements for Site Remediation at N.J.A.C. 7:26E, and 40 CFR Part 261 as incorporated by reference in the Hazardous Waste Regulations at N.J.A.C. 7:26G Subchapter 5 – Hazardous Wastes from Specific Sources.

As identified in the referenced submission, Hercules manufactured 2,4,6-trinitrotoluene (TNT) at the Facility from 1917 to 1919. Site investigation and remedial investigation activities identified TNT and related breakdown products (2,4-dinitrotoluene and 2,6-dinitrotoluene [DNTs], and 2-amino-4,6-DNT and 4-amino-2,6-DNT [ADNTs], hereafter collectively referred to as "target constituents"), in soil and groundwater. TNT encountered during site reconnaissance and investigation is represented as solid crystalline material and is not associated with either pink/red water.

To address the target constituents, Hercules developed a remedy to address TNT source mass in soil and mitigate ongoing mass transfer to groundwater. The multi-phase remedy relies on physical grain size segregation to concentrate target constituent mass in the fine soil fraction and ex-situ bioremediation to degrade target constituent mass over a short period of time (~3 months)

to achieve NJDEP non-residential direct contact soil remediation standards. The treated material will be returned to the excavation where ongoing degradation will further reduce residual target constituent concentrations to meet NJDEP's impact to groundwater standards. Natural attenuation is occurring in groundwater, and absent a soil source, target constituent concentration reductions in groundwater are expected.

Hercules has evaluated the soil and water material streams associated with the proposed remedy in the context of RCRA waste regulations and USEPA regulatory interpretations (included as Exhibit A in the submission) and noted the following:

SOIL

- Soil containing target constituents do not represent a listed hazardous waste, as the soil does not meet the definition of any explosive manufacturing K-listing codes, and target constituents are not present as commercial chemical products and, therefore, do not meet the definition of a U-listed waste.
- Soil to be excavated exhibits an average (inverse distance weighted) TNT concentration of approximately 1,800 milligrams per kilogram (mg/kg). At these concentrations, the soil does not possess the reactivity characteristic per the RCRA definition established at 40 CFR 261.23. Soils containing more than 12 percent (120,000 mg/kg) secondary explosive (such as TNT) by weight can propagate a detonation (i.e., meet the definition of reactive). Maximum TNT concentrations identified in Facility soil do not exceed this threshold. Representative soil samples collected from known source areas were analyzed for RCRA Characteristics and did not exhibit the reactivity characteristic.
- SI/RI analytical data in project area soil samples were screened to identify constituents with concentrations unlikely to exceed a regulatory level (Maximum Concentrations of Contaminants for the Toxicity Characteristic, as presented in 40 CFR 261.24). Screening identified 2,4-DNT and lead at concentrations requiring Toxicity Characteristic Leachate Procedure (TCLP) analysis to support waste characterization. Thirteen representative composite samples, each consisting of 5 discrete samples and representing 100 cubic yards of material (20 cubic yards per discrete grab), from the areas of highest target constituent and lead concentrations analyzed via the TCLP identified lead at one location at a leachate concentration exceeding the regulatory level. Soil from this area will be managed separately during TNT Bioremediation project implementation (e.g., offsite disposal as a D008 characteristic hazardous waste).

The Department agrees that based on the information provided, soil excavated in association with the TNT bioremediation project, other than those previously characterized as a D008 hazardous waste, would not be regulated as a listed or other characteristic hazardous waste.

WATER

- Process water used during TNT bioremediation activities will originate from potable water wells, and is not associated with former TNT manufacturing operations.
- Bioremediation process water recirculated between the soil processing plant, bio cells, and water storage basins would not be considered a regulated waste stream until water use ceased at the conclusion of the remediation project.

- Based on the definition of K047 waste provided in the Federal Register, which incorporates the definition provided in the May 1980 background document (EPA 1980) via reference with the waste code adoption, the process water would not constitute a K047 waste because it was not associated with the production and formulation of TNT and TNT containing formulations and products.
- Based on the definition of K111 waste provided in the Federal Register, the bioremediation process water would not constitute a K111 waste because it was not a product wastewater generated during the production of DNT via the nitration of toluene.

The Department agrees that based on the information provided, the process water would not be a listed hazardous waste. Analysis of the bioremediation process water waste stream for RCRA Characteristics would be appropriate to assess whether it represents a regulated hazardous waste based on the reactivity or toxicity characteristic(s) when managed to disposal.

The Department agrees with the findings and recommendations in the subject submission and has determined that the RCRA Hazardous Waste Classification Request (dated July 1, 2020), is in compliance with the Technical Requirements for Site Remediation, N.J.A.C. 7:26E and other applicable requirements. The Department hereby approves the RCRA Hazardous Waste Classification Request (dated July 1, 2020), effective the date of this letter.

If you have any questions regarding this correspondence, please feel free to reach me by phone at (609) 984-4079, or email at *Marianna.Cosentino@dep.nj.gov*.

Dear Mr. Meeks:

On behalf of Hercules Incorporated (Hercules), ARCADIS prepared this technical memorandum to evaluate technical approaches for separation of 2,4,6-trinitrotoluene (TNT) particles from soil and recommend a path forward for the development and application of the chosen technology at the former Hercules Kenvil Works Facility (the site) located in Kenvil, Morris County, New Jersey.

Introduction

The site manufactured components of explosives and energetic (E&E) for more than 100 years. During this time, operational process failures (e.g., fires, explosions, spills) resulted in the release of E&E compounds to soil. Erosion and other natural process have mobilized E&E constituents into other environmental media at the site (e.g., groundwater).

Through the site investigation process, Hercules has developed a conceptual site model that defines the magnitude and extent of E&E impacts, specifically TNT and its associated breakdown products (dinitrotoluenes [DNTs] and amino-DNTs). Residual solid-phase TNT in surface and shallow subsurface soil in former operational areas of the site serves as an ongoing source to groundwater. The biodegradation of TNT and its breakdown products in groundwater is being studied at the site, and the results indicate that natural biodegradation will be sufficient to address groundwater impacts attributable to TNT and its breakdown products, contingent upon the removal of the source material in unsaturated soil that leaches to groundwater. Residual TNT

material in a solid crystalline form exists in site soils across a range of grain sizes, from masonry brick-sized chunks to fine particles similar to sand and silt. These source materials need to be segregated and removed from the soil matrix to eliminate the TNT mass in soil that represents an ongoing source to groundwater. Removal of the mass, particularly the particles with a low surface area to volume ratio, will effectively reduce the duration over which biodegradation will need to occur to meet applicable groundwater quality remediation goals.

As such, the primary treatment objectives for technologies being considered are:

- Remove solid-phase TNT mass (e.g. nodules) from overburden soils
- Provide clean soil fractions suitable for on-site backfill at reasonable cost of implementation
- Prepare remaining soil fractions for further treatment via biodegradation (if necessary)

Identification and Evaluation of Alternatives

Soil remediation technologies vary widely in technical approach and remediation endpoint. A survey of publically-available literature, case studies and regulatory documents was used to identify remedial technologies potentially applicable to TNT and the site setting. Attachment 1 presents a list of citations and sources used to develop the list of technologies and support the evaluation.

The survey identified the following technology types and approaches for consideration:

- Excavation and Offsite Disposal
- In-situ Stabilization
- Ex-situ Thermal Treatment
- Ex-situ Composting (Biofarming)
- Ex-situ Physical and Density Separation

Attachment 2 provides a matrix that evaluates each technology type in the categories listed above: The table below summarizes the results of the evaluation. In some cases, the approaches evaluated represent categories that may encompass multiple remedial technologies. Where applicable, the differences among individual technologies are noted in the matrix (Attachment 2).

The following table summarizes the technologies evaluated.

Technology	Effectiveness	Implementability	Cost	Comments
Excavation & Disposal	H	M-H	H	Traditional technique, costly, material may require additional treatment (i.e., stabilization) to meet disposal facility acceptance requirements
Stabilization\ Solidification	L-M	L-M	M	Stabilization of TNT difficult, bulking process increases disposal volumes, potential impacts to soil bio/geochemistry and biodegradation processes
Thermal Treatment	M	M	H	Costly, requires physical manipulations to size feed material, difficulty treating moist soils (e.g., red water lagoon area)
Composting	L	H-M	H-M	Ineffective for solid-phase crystalline TNT
Physical and Density Separation	H	H	M	Minimizes volume of material disposed of offsite, high production rate, low operating costs, flexible endpoint compliments biodegradation work completed to date

L – Low, M – Moderate, H – High

Conclusions

Based on the matrix evaluation, ex-situ Physical and Density Separation provides a scalable, cost-effective solution that meets the primary treatment objectives stated above.

The remainder of this memorandum outlines a conceptual approach to removing TNT from soil using Physical and Density Separation processes.

Physical Separation Conceptual Approach

The overall objective of the Physical and Density Separation process will be to remove TNT mass (primarily in the crystalline solid phase) from soil to meet at a minimum NJDEP industrial standards for TNT and other secondary contaminants such that unsaturated overburden soils do not continue to influence dissolved phase TNT concentrations in groundwater.

The Physical and Density Separation process would achieve the following:

- Remove solid-phase TNT mass (e.g. nodules) from overburden soils including gravel, sand and silt with particle size greater than 0.040 millimeters (mm)

- Isolate fine soil fraction less than 0.040 mm, and prepare for further treatment via biodegradation (if necessary)

A treatment process achieving these goals will generate a number of residual product streams, including oversized material (>2.4 mm), sand (2.4 mm down to 0.040 mm), filter cake (fine material less than 0.040 mm), and TNT concentrate. Typical removal efficiencies associated with this treatment technology yield near-complete removal of TNT from the oversized and sand fractions, and once optimized, may achieve NJDEP regulatory standards for TNT-related constituents in the filter cake material as well. Under these circumstances, treated soil fractions would be homogenized and returned to the excavations as backfill. The TNT concentrate would require offsite destruction (i.e., incineration). In the event that the filter cake fraction does not meet applicable regulatory standards, multiple secondary options exist. These options include, but are not limited to, blending with larger grain size residual product streams to reduce mass TNT per unit volume and created acceptable backfill material, short-duration biofarming onsite to achieve additional reductions in TNT concentrations, or offsite disposal.

Understanding that the DuPont/Georgia Tech research team has shown that natural biodegradation will address residual leachable TNT concentrations, coordination with this research team will be required to identify what particle size and/or residual TNT concentration in soil will be treatable via natural biodegradation over the target timeframe.

The following section presents a conceptual plan outlining the components and a process train associated with a Physical and Density Separation approach to removing TNT from site soil.

Physical and Density Separation Processes

A conceptual process flow diagram for Physical and Density Separation Process is provided as Attachment 3. The Physical and Density Separation Process is a closed-loop, water-based process consisting of a combination of physical processes including wet screening, fines separation, density separation, flotation and dewatering. Details of the process will be determined in the proposed treatability study.

Technical and Feasibility Considerations

During a December 2012 site visit, Hercules provided an overview of the source areas, site infrastructure, and conceptual timeline for remedial action implementation. Based on the information obtained at this site visit and during subsequent discussions with Hercules regarding the physical separation approach, the following observations related to the technical feasibility of implementing such a remedy onsite were made.

- Source areas readily accessible and target material is shallow
- Site provides infrastructure appropriate for onsite treatment plant construction and operation
- Physical characteristics of site soil and TNT nodules are amenable to physical and density separation processes
- Estimated source material volume results in competitive estimated per ton treatment costs
- Cooperative agreement with DuPont and Georgia Tech offers other opportunities to adapt treatment technology to other sites, further reducing the per ton cost of treatment

Coordination with DuPont and Georgia Tech Remedial Research

The biodegradation work being done by DuPont and Georgia Tech indicated that the success of biodegradation is dependent on concentrations and size of TNT particles.

The optimum remediation approach using any combination of Physical and Density Separation treatment and biotreatment for the filter cake as a complete treatment train will be explored and coordinated with DuPont and Georgia Tech.

Treatability Study Plan

A treatability study is recommended to prove out and develop the conceptual approach presented herein. The testing would serve as a bench-scale proof of concept and identify where scaling factors are needed to design an implementation-scale treatment process.

The scope and objectives of the treatability study would be presented in a treatability study plan. The plan would include a field sampling plan, outlining the procedures for collecting representative materials from across the source areas defined onsite in proportional quantities. The study plan would also include project elements such as identifying quantities of material that trigger shipping/handling/management requirements, and listing how the study activities will comply with applicable federal, state and local regulations governing the transport and processing of material containing listed E&E constituents.

The study plan would detail the different separation techniques used in the laboratory to process the material collected in the field and separate it into the various process streams outlined in the Attachment 3. Bench-scale tests would identify effective processes, and those that may need to be refined as part of scaling the design up to full scale. Laboratory testing requirements, parameters, methods and frequencies will be established in the study plan, such that the TNT removal efficiency and constituent concentrations in each process stream can be identified. In addition, the bench-scale testing will generate sufficient quantities of each process stream (e.g., > 0.040 mm, <0.040 mm, TNT concentrate) to enable appropriate biodegradation testing by DuPont and Georgia Tech, and characterization for those parameters needed for transportation and disposal of the TNT concentrate.

Given the innate link between the bench-scale testing associated with the physical separation and the biodegradation work that DuPont and Georgia Tech are conducting, frequent communication between the two project teams will be required as separation techniques and processes are refined and the results of laboratory testing are evaluated.

Summary

An evaluation of potential remedial technologies capable of removing solid TNT mass from soil identified a physical and density driven separation process as the most appropriate based on the scalability, flexibility and adaptability of the processes used to separate the materials, and the ability to minimize the volume of material requiring offsite disposal (incineration of the TNT concentrate).

A conceptual process flow diagram was developed to illustrate the various techniques and processes used to separate the heterogeneous source material into a number of homogenous process streams from which TNT material would be removed. Removal efficiency from material down the 0.040 mm would result in material able to be used as backfill onsite. Proof of concept testing and refinement would identify the removal efficiency and TNT concentration remaining in the material less than 0.040 mm in size, and identify the most efficient and effective treatment method to reach appropriate performance standards.

Overall, the information compiled to date indicates that process-specific and site-specific conditions are well-suited for the conceptual approach outlined above and that the capabilities of this technology meet, and in many cases exceed, the preliminary performance standards discussed with Hercules. Based on the information contained herein, the ARCADIS and ART Engineering LLC (ART) team recommend the development of a treatability study plan and initiating discussions with the DuPont and Georgia Tech research team.

ARCADIS and ART appreciate the opportunity to support Hercules on this project and look forward to working together through the development and implementation of this remedy.

Sincerely,

ARCADIS U.S., Inc.

Remedial Technology	Technology Overview	Effectiveness Evaluation		Implementability Evaluation		Relative Cost Evaluation		Site-Specific Pros & Cons
Excavation and Offsite Disposal	Mechanical removal of soil matrix and associated constituents to a target depth and extent. Excavations would be backfilled with certified clean fill material. Excavated material would be transported via truck to an appropriately licensed offsite disposal facility, or an offsite recycling facility for treatment and reuse by accepting facility.	High	- Permanently reduces the mobility, toxicity, and volume of constituents in soil by removing them from the site - Backfill material permeability can be selected to match biodegradation test environment conditions - Effective at addressing both solid-phase and residual product in soil	Moderate-High	- Excavation utilizes standard construction equipment and methods - Landfilling is a proven and accepted disposal technology - Transportation requires DOT profile - Additional measures (e.g. stabilization or pre-treatment) may be required to meet disposal facility acceptance criteria.	High	- Moderate to high capital costs depending on depth and volume - Disposal costs are dictated by volume and waste classification results (i.e., hazardous or non-hazardous) - Additional expenditures associated with testing and procurement of backfill material - Additional costs associated with any pre-treatment necessary to meet facility acceptance criteria.	PRO: - Complete contaminant removal, eliminates need to rely on percolation and biodegradation to treat TNT and breakdown products in soil in excavated areas CON: - Backfill permeability and geochemistry may alter the subsurface conditions and impact biodegradation processes. - Results in clean surface interval only, residual material at depth left in place and still requires deed restriction
Stabilization/Solidification	In-situ blending of one or more stabilizing agents with the impacted overburden soil to form a monolithic structure that negates or minimizes contaminant leachability and eliminates receptor contact. Ex-situ stabilization commonly used to stabilize soils containing E&E constituents, used in conjunction with traditional disposal techniques	Low-Moderate	- Permanently reduces the mobility and toxicity of constituents in soil - E&E compounds may be difficult to immobilize via standard ISS methods, requires amendment to mixture (Channel 1996). - Variations include amending soil with lime to raise pH to 11 or greater and rapidly degrade TNT in-situ (Hansen et al. 2003) to address dissolved/sorbed fractions	Low-Moderate	- May be difficult to implement because of infrastructure - Existing debris may require additional activities or preclude stabilization in all areas, ex-situ pre-treatment may be required	Moderate	- High capital cost associated with in-situ mixing - Additional costs associated with management and disposal of excess/off-spec material - Process scalable, low-cost bench-scale testing used to develop process in lieu of field pilot testing - Ex-situ stabilization only costs (ex-situ) ~$70 (excl. disposal) to $200 (incl. disposal) per cubic yard (cy) (Channel 1996, Van Deuren et al. 2002)	PRO: - Complete contaminant removal, eliminates need to rely on percolation and biodegradation to treat TNT and breakdown products in soil in excavated areas - Results in material volume increase ranging from 20 to 100 percent depending on stabilizing agents used; material may be suitable for use as fill elsewhere onsite CON: - Creates an impermeable monolithic feature in areas where surface-water infiltration/percolation facilitates biodegradation of TNT in groundwater - Results in material volume increase ranging from 20 to 100 percent depending on stabilizing agents used; offsite disposal or additional - Alternative in-situ treatment (i.e., liming) would alter soil geochemistry and likely impact
Ex-Situ Thermal Treatment (Incineration)	Mechanical excavation of soil matrix and associated constituents to a target depth and extent. Excavated material stockpiled and incinerated in an incinerator plant constructed onsite. Combustible materials (e.g., organic compounds) destroyed via incineration. Remaining mineral soil and inorganic material available for reuse.	Moderate	- Permanently reduces the mobility, toxicity, and volume of certain constituents in soil via thermal destruction - Effective at reducing organic constituent concentrations (i.e., E&E, PAHs) - Ineffective for treatment of inorganic constituents (i.e., metals) - Effective at addressing both solid-phase and residual product in soil - Treated material can be reused onsite	Moderate	- Standard technology that is readily available, limited number of USEPA-approved portable incinerators - Air discharge permitting required, permit conditions may limit effectiveness and/or efficiency - Limitations associated with material feed size and handling requirements, may require pre-treatment - Transportation to offsite incinerator vs. mobilization of portable incinerator to site	High	- High capital and operating and maintenance costs associated with fuel and equipment - $800 to $2,500 per cy (Channel 1996, Van Deuren et al. 2002)	PRO: - Space available onsite for construction of treatment plant - Enables reuse of treated material as backfill onsite CON: - Soil from Red Water Lagoon area will have high moisture content, increasing thermal input needed to dry the material then consume the organics - consume time and resources (fuel) incinerating large crystalline TNT nodules, effective treatment may require physical manipulation of source material to segregate by particle size - availability of fuel, site serviced by natural gas?
Ex-Situ Composting (Biofarming)	Mechanical excavation of soil matrix and associated constituents. Material stockpiled in windrows. Relies on natural breakdown of constituents by biotic (e.g., microorganism metabolism) and abiotic (e.g., photodegradation) processes. Active treatment of piles (e.g., aeration, watering) required to facilitate breakdown processes.	Low	- Permanently reduces the mobility, toxicity, and volume of constituents in soil - Degradation process creates contaminant daughter/breakdown products - Effective at reducing sorbed and dissolved phase organic constituent concentrations - Ineffective for treatment of large solid phase particles with low surface area to volume ratios	High - Moderate	- Proven technology for target constituents - Requires pretreatment (i.e., removal of large particles) - Requires large areas of open space	High - Moderate	- Costs commensurate with amount of pre-treatment and/or soil handling required - Procurement costs associated with selected amendment (alfalfa, wood chips, etc.) - Potential cost associated with handling/disposal of excess material, composting increases material volume by 50-100% (Craig and Sisk 1994) - Approximately $350 to $500 per cy (Channel 1996, Van Deuren et al. 2002)	PRO: - Space available onsite for stockpiling and manipulation - Enables reuse of treated material as backfill onsite CON: - Ineffective/time consuming for treatment of crystalline TNT nodules - effective treatment may require physical manipulation of source material to segregate by particle size - Relies on amendments that increase final volume of treatment material, excess material remains following backfilling - Toxicity of concentrated TNT (i.e., solid nodules) may inhibit microorganism activity (Ghosh and Luthy)
Ex-Situ Physical Separation (Soil Washing)	Mechanical excavation of soil matrix and associated constituents. Material sorted, sized and separated by physical manipulations in a plant constructed onsite. Based on proven mineral process and mining technologies. Relies on differences in physical material properties (e.g., density, grain size) to separate and concentrate TNT mass from soil fraction. Treated soil available for reuse (some fractions may require additional treatment), TNT concentrate disposed of offsite via incineration.	High	- Permanently reduces the mobility, toxicity, and volume of TNT in soil by removing it from the site. - Treated soil fractions can be reused. - Requires additional steps to address concentrated TNT (e.g., incineration, disposal)	High	- Technology frequently used and commercially available - Requires treatability testing to optimize effectiveness and process details - High production rate compared to other ex-situ treatment options (i.e., thermal)	Moderate	- Moderate capital costs, low operating costs (Dermont et al.) - Process scalable, low-cost bench-scale testing used to develop process in lieu of field pilot testing - $50 to $150 per cy (Van Deuren et al. 2002)	PRO: - Space available onsite for stockpiling and treatment plant - fast remedy, high production rate (~50 tons per hour) - Enables reuse of treated material as backfill onsite - Volume reduction technology, concentrates TNT to minimize volume of material requiring incineration/disposal - Similar processes would be required to pre-treat site soils ex-situ in conjunction with other remedies evaluated - complimentary to the bioremediation approach for sorbed and dissolved phase constituents CON: - Volume reduction technology, certain process streams (e.g., filter cake, wash water) may require additional treatment of residual and dissolve phase constituents.

Mr. Meeks:

On behalf of Hercules Incorporated (Hercules), the ART Engineering LLC (ART) and ARCADIS team prepared the attached *Soil Separation Treatability Study Report* (the report) presenting the results of the treatability testing conducted between June and October 2013. The treatability study evaluated the feasibility of separating 2,4,6-trinitrotoluene (TNT) from soil at the former Hercules Kenvil Works Facility located in Kenvil, Morris County, New Jersey (the site). Consistent with the *Treatability Study Work Plan* (ART and ARCADIS 2013a), testing focused on multiple physical separation processes to develop a treatment process capable of achieving an 85 percent TNT mass removal target.

Following the completion of Round 1 testing outlined in the *Treatability Study Work Plan* (ART and ARCADIS 2013a), the ART and ARCADIS team proposed supplemental study of treated soil using oxidation to further reduce target constituent (TNT and 2,4-dinitrotoluene [DNT]) concentrations in an effort to meet the New Jersey Department of Environmental Protection's (NJDEP's) Non-Residential Direct Contact Soil Remediation Standards (NRDCSRS). The scope and objectives of the oxidation study were outlined in an August 23, 2013 scope of work.

The attached report presents the results of both the physical separation testing as well as the supplemental oxidation testing. In brief, the report indicates the following:

- Physical separation is an effective method of separating solid phase TNT from site soil

- Separation efficiency for sand and coarser fractions exceeds the 85 percent target

- Oxidation treatment of sand and fines fractions achieves target constituent concentrations at or less than NRDCSRS

Individual treatment processes tested and selected to achieve these results balanced effectiveness and scalability to the field (e.g., operational costs, reliability, and production rate). For instance, where two techniques or processes were effective at achieving the target, the chosen option was the one that would most efficiently achieve similar results at full scale.

Based on the findings of the treatability testing, the report recommends three options for full-scale treatment. Each of the three options relies on the physical separation treatment process developed during treatability testing and achieves the 85 percent removal objective. Options 2 and 3 build upon the end result of Option 1 to attain target constituent levels at or below the NRDCSRS for certain fractions via oxidation.

These options include:

- Option 1: Physical Separation, including oversize grinding and sand treatment using attritioning and flotation

- Option 2: Option 1 with Chemical Oxidation of Sand Fraction

- Option 3: Option 1 with Chemical Oxidation of Sand and Fines Fractions

The physical separation process generates five material streams: 1. Coarse Debris, 2. Coarse Oversize, 3. Sand, 4. Fines, 5. Flotation Concentrate, and 6. Process Water.

Following physical separation, Coarse Debris and Coarse Oversize will be stockpiled for reuse as clean fill material onsite; the flotation concentrate will be sent offsite for incineration/disposal; and the Sand, Fines and Process Water will require additional treatment and/or disposal. Oxidation treatment addresses residual TNT in the Sand fraction (Option 2) and Sand and Fines fractions (Option 3). Collectively, the Sand and Fines fractions will make up approximately 90 percent of the processed material.

Estimated implementation costs associated with each option are summarized in the table below.

Estimated Costs*	Option 1	Option 2	Option 3
Capital Cost	1.8M	2.5M	2.7M
Operating Cost	3.5M	6.0M	6.5M
Total Cost	5.3M	8.5M	9.2M
Treatment Endpoints	98% TNT mass removal from Coarse Oversize and Sand fractions	Coarse Oversize and Sand fractions meet NJDEP NRDCSRS	Coarse Oversize, Sand and Fines fractions meet NJDEP NRDCSRS
Additional Treatment Required	Sand and Fines fractions	Fines fraction	None

Notes:

* - Development of planning-level cost require additional engineering and design work

Excludes additional treatment costs (i.e., Sand and Fines fractions)

Excludes disposal costs (i.e., Flotation Concentrate, Process Water)

Option-specific assumptions provided in Section 4 of the report

A secondary objective of the treatability study involved evaluating the incremental cost associated with achieving the NJDEP NRDCSRS once the 85 percent TNT mass removal had been achieved. The estimates above do not include disposal costs for material streams that do not meet the NJDEP NRDCSRS, thus the deltas between costs for each option above need to consider the fractions requiring offsite disposal. ARCADIS will work with Ashland to generate disposal estimates and refine the incremental costs between the options presented above.

As indicated in the *Technical Memorandum – Evaluation of Alternatives for Separation of TNT from Soil* (ARCADIS 2013), bioremediation may provide an alternate means of achieving more stringent objectives for both the Sand and Fines fractions once the 85 percent mass removal target has been met. This alternative may also provide a means of recycling Process Water from the physical separation process to avoid treatment and disposal costs. The incremental costs associated with this option will be evaluated following implementation of a bioremediation pilot study.

Finally, field observations during the treatability test field sampling indicated that the TNT concentration contours developed to support delineation during the remedial investigation may overestimate the areal extent of TNT impacts at concentrations greater than NRDCSRS (i.e., requiring treatment). In conjunction with the continued development of the technical approach outlined above, ARCADIS will prepare a sampling plan to refine the extent of TNT impacts and develop an excavation plan and associated soil volumes requiring treatment. This information will inform the engineering of the treatment plant and estimation of associated operational costs.

ARCADIS and ART appreciate the opportunity to support Hercules on this project and look forward to working together through the continued development and implementation of this remedy.

Sincerely,

ARCADIS U.S., Inc.

EXECUTIVE SUMMARY

ART Engineering, LLC (ART) in joint effort with ARCADIS US, Inc. (ARCADIS), the “Team”, performed a Soil Separation Treatability Study evaluating the feasibility and effectiveness of physical separation techniques for removal of solid-phase, crystalline 2,4,6-trinitrotoluene (TNT) from TNT-impacted soils at the Former Hercules Kenvil Works Facility, Kenvil, New Jersey (the “Site”). Extensive soil characterization, physical separation and chemical oxidation treatment testing was performed. The Team has come to the following major conclusions regarding the soil treatment aspect of this project:

- Soil separation technology for this project is a viable technology
- Based on the results of this study, three options of soil treatment process flow diagrams are presented for consideration:
    1. Option 1- Physical Separation only with oversize grinding and sand treatment using attritioning and flotation
    2. Option 2- Like Option 1 with Chemical Oxidation of Sand Fraction
    3. Option 3- Like Option 1 with Chemical Oxidation of Sand and Fines

Schematic Process Flow Diagrams (PFD) for each of the proposed treatment options are included as part of this executive summary as Figures A, B and C. Each of the PFD diagrams include the projected product tonnages, volume reductions and projected concentrations of TNT, DNT and Pb in various products.

The proposed Physical Separation process includes the following steps: wet screening, grinding of the oversize fraction to be processed as sand, attrition scrubbing of the sand to break down TNT particles within the sand fraction; removal of TNT particles from the combined sand & ground oversize fraction using froth flotation, final sand dewatering, fines dewatering and water recycling. These processes support each of the three options above. In Options 2 and 3, an oxidation step is added to the end of the process train for target treatment media (i.e., sand or sand/fines fractions).

For a full-scale plant, a feed rate on the order of 35 tph is anticipated for Plant Option 1. For plant Options 2 and 3, the production rate may be reduced to about 20 - 25 tph and operating and reagent cost would increase.

1.0 INTRODUCTION

1.1 BACKGROUND

This Soil Separation Treatability Study evaluates the feasibility and effectiveness of physical separation techniques for removal of solid-phase, crystalline 2,4,6-trinitrotoluene (TNT) from TNT-impacted soils at the Former Hercules Kenvil Works Facility, Kenvil, New Jersey (the "Site"). Full-scale treatment will target impacted areas within the former TNT Area in the southwestern corner of the site (Figure 1). Based on physical and chemical characterization data collected during the site investigation/remedial investigation, four primary areas within the TNT area have been identified to support the treatability study. Figure 1 illustrates these areas.

This study was performed in general accordance with the approved "TNT Soil Separation Treatability Study Work Plan", Hercules' Former Kenvil Works Facility, prepared by ART/ARCADIS, May 2013. In addition to testing of physical separation techniques for removal of solid-phase TNT, chemical oxidation was also tested for destruction of residual TNT and 2,4 DNT (DNT) compounds to meet NJDEP Non-Residential, Direct Contact Soil Remediation Standard.

The primary objectives of this treatability study were to:

- Assess soil variability
- Identify the range of achievable volume reductions (total volume of clean material vs. impacted residuals)
- Demonstrate a TNT mass removal efficiency of at least 85 percent
- Support development of a full-scale design
- Develop conceptual, full-scale soil treatment process configuration
- Estimate full-scale treatment costs, including incremental costs for removal efficiencies greater than 85 percent

The secondary objectives were:

- Evaluate the ability to meet the New Jersey Department of Environmental Protection (NJDEP) Non-Residential, Direct Contact Soil Remediation Standards (NRDCSRS) for TNT and other target constituents (e.g., 2,4-dinitrotoluene [DNT], lead) in treated soil
- Prepare fines fraction for characterization and bio-treatment testing
- Identify the need for supplemental optimization studies (if required)

The remainder of this report presents the results of the Soil Separation Treatability Study, conclusions and recommendations, and a conceptual approach for full-scale treatment are presented in this report.

1.2 STUDY ORGANIZATION

This Soil Separation Treatability Study was performed in separate rounds of testing, as follows:

Round 1A: Soil Characterization and Basic Separation
Round 1B: Sand and Oversize Treatment Testing
Round 2: Process Optimization Testing
Round 3: Process Simulation and Chemical Oxidation

After performance of each round of testing, samples were shipped to Lancaster Laboratories, Lancaster, PA. A review of analytical results from the previous round of testing informed the scope of the next round of testing. Results, findings and decision criteria used to adjust the technical approach based on testing results are discussed in this report.

Tables, figures and appendices are cited throughout the text. Photo documentation of the study is provided in Appendix A. Raw data sheets are provided in Appendix B. Analytical reports are provided in Appendix C.

2.0 FIELD SAMPLE COLLECTION

A review of physical and chemical characterization data collected during the site investigation/remedial investigation identified four primary areas within the TNT area where TNT concentration contours denoted soil with TNT concentrations exceeding the NJDEP Non-Residential, Direct Contact Soil Remediation Standard (NJDEP - NRDCSRS). Field sampling to generate soil for the treatability study focused on these four areas.

Field sample collection was performed on June 11 and 12, 2013. A total of eight (8) test pits at four different locations were excavated using a small excavator. The presence and relative concentration of TNT-impacted soil at each test pit location was assessed in the field visually (e.g., visible chunks of TNT) and an EXPRAY test kit. Coordinates of each test pit location were recorded using differential GPS. Test pit locations are shown in **Figure 1.**

At Locations 1 and 2, three test pits were excavated at each location for a total of six test pits. Samples were collected from each of the six test pits. At Location 3, TNT chunk were visible on the soil surface and soil lithology was generally consistent across the area. As such, only one test pit was excavated from a representative location at Location 3. Location 4 included two smaller, discrete areas; a shallow lagoon and the location of a former filter house pipeline failure. The shallow lagoon was flooded with approximately one foot of standing water. No particulate TNT was observed at either location, however, positive identification of TNT was made using the EXPRAY test kit. Due to limited excavator access and presence of water, a sample of submerged soil/sediment was collected using a hand held shovel.

Approximately 50 to 60 lbs. of representative soil was collected from each test pit. A schematic diagram for the sample collection program and preparation of composite samples at each Location is provided in **Figures 2, 3 and 4**. The soil collected from each test pit was screened in the field to remove coarse materials greater than 2 inches in diameter. The weights of resulting fractions of material greater than 2 inches diameter and less than 2 inches were determined in the field using a portable scale. The soil fraction greater than 2 inches was excluded from the soil sample collected for purpose of this study. The weights recorded during field screening at 2 inches are included in Appendix B.

Each of the composite samples were sampled for initial TNT analysis prior to shipment. Once the results of the initial analysis were available, the composite samples were transported to the ARCADIS Laboratory in Durham, North Carolina. This transport was performed as a dedicated transport performed by an ARCADIS technician. Residual sample material which was not used to prepare the composite samples, was archived at the Kenvil site for potential shipment to ARCADIS Laboratory, in case additional sample material was required for the study. The four composite samples were received in good order at the ARCADIS laboratory on June 21, 2013.

3.0 SOIL SEPARATION TREATABILITY STUDY

3.1 Round 1 Testing

Round 1 testing included the initial homogenization and pre-screening of each of the four composite soil samples, chemical analysis, determination of the soil particle size distribution, performance of a basic separation of the soils into various size fractions and chemical analysis of these fractions. A schematic representation of Round 1 testing is provided in **Figure 5.**

In the course of Round 1 Testing, a fast turnaround semi-quantitative field method was developed using EXPRAY TNT detection spray. This method consisted of extracting 5 gram of soil with 5 grams of acetone. After a few minutes of extraction time, the acetone extract was decanted, and two drops of the acetone extract were put on a Whatman filter. After 10 to 15 seconds wait, a light spray of EXPRAY was applied to the Whatman filter. The intensity of the color after EXPRAY could be compared to a standard color chart prepared from acetone extracts with known TNT levels. The standard color chart was prepared fresh on a daily basis. This method has proved to be very useful in guiding the treatability study and has been used throughout the performance of the study.

3.1.1 Initial Analysis and Particle Size Analysis (Round 1A)

Results of the soil particle size analysis for the four composite samples are presented in **Table 1** and **Table 2**. The results indicate following ranges in particle size distribution:

Oversize (2.0 - 50mm):	27% - 46%
Sand (0.038 - 2.0 mm):	54% - 76%
Fines (<0.038 mm):	6% - 29%

Initial analysis on untreated composite samples indicated TNT concentrations ranged from 4,200 mg/kg TNT to 28,000 mg/kg TNT (**Table 3**). Levels of 2,4 DNT (DNT) ranged from 33 to 2,400 mg/kg DNT.

The concentration of Lead ranged from 198 to 1,580 mg/kg. Lead was below NJDEP Non-Residential, Direct Contact Soil Remediation Standard of 800 mg/kg in all composites except for Composite 2. The extent of Lead contamination in TNT impacted soils needs to be better defined in relationship to impacted soils volume in each area to understand the impact of this parameter on full-scale remediation.

3.1.2 Basic Separation (Round 1A)

For each soil composite, approximately 10 lbs. of soil was separated into various size fractions as follows:

- Oversize (25 - 50 mm)
- Oversize (12.5 - 25 mm)
- Fine Oversize (2.0 - 12.5 mm)
- Sand after hydraulic separation (~0.038 - 2.0 mm)
- Fines (< ~0.038 mm)

Each of the soil fractions was analyzed for TNT, DNT and Lead **(Table 3)**. Contact wash water was analyzed for dissolved TNT and DNT **(Table 4).**

The results indicate that TNT and DNT are present in all soil size fractions less than 25 mm. The presence of crystalline particulate TNT was noted in Composites 1, 2 and 3. The results indicate that a “simple” particle size separation process will not be effective in producing clean soil fractions. Instead, the treatment process will need to address removal of TNT particles from each size fraction.

3.1.3 Rationale for Preparation of Combined Composite Sample C1 & C2 for Plant Process Design Basis

When considering the representativeness of the four composites related to the total volume of TNT impacted soils to be treated, Composite 1 (C1) and Composite 2 (C2) are believed to represent the majority of TNT impacted soils requiring treatment at the Site. Both Composite 1 and

Composite 2 were prepared from material collected from three test pits each. Composite 3 (C3) was collected from a small localized area from one single test pit and is believed to represent only a small volume of total soils. Composite 4 (C4) was collected from two local drainage areas which are believed to represent a small volume of total impacted soils.

Therefore, a "site representative" combined composite was prepared by combining equal weights of C1 and C2. This combined composite "C1 & C2" was used in all following rounds of testing performed as part of this study for determining the process design. The small amount of soils represented by Composite 3 and Composite 4 can be blended into the main plant feed during full-scale remediation for processing and do not affect process design.

The particle size distribution for the composite sample was determined directly on the composite sample and compared to calculated average particle size distribution **(Tables 5 & 6)**; there is a good agreement between the calculated and measured results. **Table 7** presents the calculated expected contaminant levels in various soil separation products for the Composite C1 & C2.

3.1.4 Oversize Treatment Testing – Combined Composite C1 & C2 (Round 1B)

For treatment of the oversize soil fractions (2 – 25 mm), two techniques were considered: 1) Density Separation, and 2) Attrition Grinding. Attrition grinding would be the preferred technique for full-scale implementation as this technique is easier to implement operationally at full-scale and can be implemented at a lower cost as compared to density separation. Therefore, this treatability study focused on the use of attrition grinding. Attrition grinding involves the use of mild attritioning in a grinding mill for the purpose of selectively breaking down the TNT particles to finer particle size, while not affecting the hard native rock/gravel. Following the attrition grinding, the broken down TNT particles could then be removed by physical separation.

Three tests were performed as follows: 1) Autogenous grinding without special grinding media added; 2) Grinding with 5/8" dense alumina ceramic grinding media; and 3) Grinding with 9.5 mm steel grinding media. A schematic representation of the testing program is presented in **Figure 6**. The results of the tests are presented in **Tables 8 & 9.**

The results indicate that each of the three attrition grinding tests were not aggressive enough to breakdown the TNT particles. TNT levels in each of the oversize fraction after attrition grinding ranged from several hundred to around a thousand milligram per kilogram (mg/kg). It was concluded that for the attrition grinding to be effective treatment, the grinding has to be more aggressive. More aggressive grinding was tested in the Process Optimization Testing performed in Round 2.

3.1.5 Sand Treatment Testing (Round 1B)

For the removal of TNT from the sand after hydraulic separation, the following physical treatment techniques were evaluated:

- density separation
- attrition scrubbing
- attrition grinding
- froth flotation

All treatment techniques proposed for evaluation in this study are directly scalable to commercially available techniques that can be incorporated into a full-scale production plant for the Site.

The following facts were considered in the initial selection of the treatment techniques:

- TNT has lower density (s.g. 1.65 g/cm^3) compared to the soil grains (s.g. ~2.6 g/cm^3)
- TNT occurs predominantly in form of discrete particles
- TNT particles are weakly hydrophobic and might be amenable to removal via froth flotation; this technique is based on the use of

dispersed air to float TNT particles to the surface to be removed by skimming of a froth

A summary of the sand treatment testing program is provided in **Figure 7**.

Density separation was tested first and was not found to be effective in separating TNT particles from the sand fraction (Ref. Photos - Appendix A). It appears that the density difference between TNT particles and soil grains is not large enough to effectively separate the TNT particles based on density difference.

Results for treatment of the sand fraction using Attrition Scrubbing, Attrition Grinding and Flotation, are presented in **Table 10**. The results indicate that the best results were achieved when using aggressive scrubbing or attrition grinding, each in combination with flotation. As aggressive scrubbing is easier and more economical to implement at large scale, as compared to attrition grinding, aggressive scrubbing in combination with flotation is the preferred treatment approach. Through combination of attrition grinding and flotation, the total concentration of TNT in the sand fraction after hydraulic separation was reduced from 8,200 mg/kg TNT to 110 mg/kg. For the sand fraction, a contaminant mass removal efficiency achieved was on the order of 98% for TNT, 96% for DNT and 65% for Lead.

3.1.6 Round 1 Testing – Discussion of Findings

The results of Round 1 tests were promising in removing the bulk of the TNT mass from the soil matrix through use of physical separation, attrition scrubbing and removal (separation) of particulate TNT using froth flotation. Density Separation for removal of crystalline TNT particles from the sand fraction was tested, but found to be ineffective. It appears that the density difference is not a large enough difference to effectively separate the TNT particles based on density difference.

Considering that density separation was not effective, and the fact that the crystalline TNT particles are softer as compared to the native rock, the process optimization testing in Round 2 focused on the use of methods which would selectively breakdown the crystalline TNT with subsequent removal of TNT particles via froth flotation.

3.2 Round 2 Testing

The purpose of Round 2 Testing was to perform additional process optimization testing of selected process treatment steps. These treatment steps tested in Round 2 include: selective grinding of oversize, attrition scrubbing of the sand, and subsequent removal of TNT particulates after attrition scrubbing via froth flotation. In Round 2 testing, two different process optimization runs (Run A and Run B) were performed (**Figures 8 & 9**). The main difference between testing Run A and Run B was how the oversize fraction 2.0 - 25 mm was processed.

In Run A (**Figure 8**) the oversize fraction (2.0 - 25 mm) was ground with a mixture of 3/8" and 5/8" steel grinding balls and analyzed for particle size distribution and TNT/DNT levels in each fraction. In Run A, the ground oversize was not processed together with the native sand size material.

In Run B (**Figure 9**) the oversize fraction (2.0 - 25 mm) was ground with 1" and 1¼" steel grinding balls with the objective of achieving the most aggressive grinding of the oversize fraction. The sand size material resulting from oversize grinding was then combined with the native sand size material for processing through attrition scrubbing and flotation.

For both runs, the resulting particle size distribution and TNT concentration as function of particle size after oversize grinding was determined. A comparison of the results of the oversize grinding is provided in **Table 11**. Results of analysis of various soil fractions and mass balance for both runs are provided in **Table 12** and **Figures 8 and 9**.

3.2.1 Round 2 Testing – Discussion of Findings

The results of Round 2 Testing indicate that grinding of the oversize fraction and processing the ground oversize with the native sand size material is effective treatment. Depending on the acceptable levels of residual TNT/DNT in the oversize fraction, partial grinding as opposed to complete grinding of the oversize may be acceptable. However, to achieve the highest removal efficiency for TNT/DNT, complete grinding of the oversize fraction 2.0 - 25 mm and processing the ground oversize fraction 2.0 - 25 mm with the native sand size material is recommended.

For Run A, the final sand after scrubbing and flotation contained on the order of 130 mg/kg TNT and 58 mg/kg DNT (**Table 12**). The results of Run A compare well with results of Round 1 testing (**Table 10, Sample ID C12-Sand-FL2**) performed under similar conditions as Run A. This suggests a good reproducibility of experimental results.

For Run B, the final sand after scrubbing contained 85 mg/kg TNT and 40 mg/kg DNT. The concentration of TNT and DNT are slightly lower as compared to Run A, which suggests that the inclusion of the ground oversize provides a slight benefit to lowering the residual TNT/DNT levels in the final sand product.

Based on the results of Run A and Run B, it was decided to perform a Process Simulation with complete grinding of the oversize fraction to 100% passing 2 mm to be processed with the sand.

3.3 Round 3 Testing

A schematic diagram for the Process Simulation is provided in **Figure 10**. This program was designed to include and simulate all basic processing steps in the soil treatment process. In Round 2 testing, it was concluded that selective grinding is not sufficiently effective to breakdown the crystalline TNT in the oversize fraction. Therefore, for the Process Simulation, it was decided to grind all oversize material (2.0 - 25mm) to “sand size” material less than 2.0 mm to be processed along with the “native” sand size material. To accomplish this aggressive grinding, large 1” and 1.25” size steel grinding balls were used. After each grinding cycle, the ground material was screened at 2 mm and material

coarser than 2 mm was ground again until 100% of the oversize material passed 2 mm. The ground oversize passing 2 mm was then subjected to hydraulic separation to separate the secondary fines created in the grinding process. The ground oversize after hydraulic separation was then combined with the “native” sand after hydraulic separation. The ground oversize fines were combined with the “native” fines from primary hydraulic separation.

For each of the steps in the Process Simulation, the mass of each fraction was tracked on a dry-weight basis such that a mass balance could be prepared. As an additional task, chemical oxidation testing of sand and fines products generated from the Process Simulation was performed.

3.3.1 Process Simulation Testing Results

A mass balance and analytical results for the Process Simulation Testing are provided in **Table 13** and **Figure 10.** The results indicate that processing the ground oversize with the native sand size material is effective treatment. The final concentration levels of TNT and DNT in the treated sand were 97 mg/kg TNT and 38 mg/kg DNT respectively. These results are consistent with the results achieved during Round 2 testing. The mass balance on dry-weight basis is as follows:

Oversize Product (25 - 50 mm):	6.5%
Sand Product (0.020 - 2.0 mm):	62.5%
Fines Product (<0.020 mm):	29.9%
Flotation Concentrate:	1.1%
Total	100.0%

3.3.2 Sand and Fines Chemical Oxidation Testing

The primary evaluation objectives of testing chemical oxidation as an add-on treatment process were to:

1) Demonstrate reductions in TNT and DNT mass in the sand and fines fractions

2) Evaluate potential to achieve post-oxidation TNT and DNT concentrations in sand and fines fractions at or below the NJDEP NRDCSRS[1].

A series of chemical oxidation tests were performed on the sand and fines fractions produced as part of the Process Simulation (**Figure 10**). Tests were performed to simulate a stirred slurry reactor. Oxidation tests were performed on "sand only", "fines only" and a combination of "sand and fines". Results of the oxidation tests are presented in **Tables 14 through 19.**

The results indicate that the NJDEP treatment goal of less than 95 mg/kg TNT and less than 3 mg/kg DNT can be met through oxidation of the sand fraction (Sample ID: C1C-SAOX2). For the fines fraction (Sample ID: C1C-FIOX3), a reduction of total mass of TNT and DNT of greater than 97% was achieved. However, for the fines fraction, the NJDEP Non-Residential, Direct Contact Soil Remediation Standard of 3 mg/kg for DNT could not be attained. The benefits of potential use of Chemical Oxidation are:

- Achieves NJDEP Non-Residential, Direct Contact Soil Remediation Standard for sand product
- Removes 97% of the TNT/DNT mass from the fines fraction
- May enhance biological activity following oxidization and reduce timeline for bio-treatment

Additional laboratory study of Chemical Oxidation is required to optimize process design parameters (i.e. temperature, residence time, reagent consumption).

[1] Evaluation focused on DNT, as DNT concentrations were one order of magnitude greater than the NJDEP NRDCSRS prior to treatment (38mg/kg vs. 3mg/kg), while TNT was only slightly above the NJDEP NRDCSRS (97mg/kg vs. 95mg/kg).

4.0 FULL-SCALE SOIL TREATMENT PROCESS CONCEPTUAL APPROACH

4.1 Treatment Options

Three options of soil treatment process flow diagram are proposed for consideration as follows:

Option 1- Physical Separation only with oversize grinding and sand treatment using attritioning and flotation
Option 2- Like Option 1 with Chemical Oxidation of Sand Fraction
Option 3- Like Option 1 with Chemical Oxidation of Sand and Fines

Schematic process flow diagrams for each of the three proposed options and a calculated mass balance for "Process IN" and "Products OUT" are provided in **Figures 11, 12 and 13** and **Table 20**. A brief summary of each of the options is provided below:

Option 1 - Physical Separation only with oversize grinding and sand treatment using attritioning and flotation

The proposed soil treatment process will include the following steps: wet screening, crushing of the oversize fraction 2.0 - 25 mm to less than 2.0 mm to be processed combined with the sand, attrition scrubbing to breakdown the larger TNT particles, froth flotation to remove (float) the TNT particles from the sand slurry, sand dewatering, fines dewatering and water recycling. The projected volume reduction and process product quality for this option is presented in **Figure 11**. This option removes greater than 98% of total TNT mass from the sand and oversize fractions.

The capital cost of this plant option is estimated at about $1,800,000. Site preparation, mobilization, assembly and start-up are estimated at $350,000. Operating costs are estimated at $42/ton based on 75,000 project tons process on two ten-hour shifts per day for 5 days per week at a processing rate of 35 tons per hour.

Capital cost includes: the physical plant, pre-fitted in Florida, initial and detail engineering, fabrications and procurement, FOB Florida. This effort is estimated to require from 18 to 20 weeks. The initial engineering would be required to determine more precise cost. This effort, which is included in the capital cost, would be in the range of $65,000 and require about 8 weeks.

Site preparation, mobilization, assembly and start-up includes: shipping, receiving, off-loading, assembly, plant area preparation, electrical, plant shakedown, labor and ART management. Assembly of the plant usually requires 3 weeks. Other aspects of site preparation can be on-going as weather permits.

Operating cost includes: labor, ART management, reagents, power, water, plant feeding, excavation, backfilling. Production processing of 75,000 tons is estimated to require about 22 weeks.

Option 2 - Physical Separation with Chemical Oxidation of Sand Fraction

The proposed soil treatment process will include the same steps as for Option 1, with the addition of chemical oxidation treatment for the sand fraction. The chemical oxidation of the sand fraction will achieve a concentration of TNT and DNT below NJDEP Non-Residential, Direct Contact Soil Remediation Standard. The projected volume reduction and process product quality for this treatment option are presented in **Figure 12**.

The capital cost of this plant option is estimated at $2,500,000 (-5% +20%): site preparation, mobilization, assembly and start-up estimated at $350,000; operating costs are estimated at $75/ton based on 75,000 project tons process on two ten-hour shifts per day for 5 days per week at a rate of 25 tons per hour.

Capital cost includes: the physical plant, pre-fitted in Florida, initial and detail engineering, fabrications and procurement, FOB Florida. This

effort is estimated to require from 18 to 20 weeks. The initial engineering would be required to determine the final cost. This effort (included in the capital cost) would be in the range of $110,000 (oxidation optimization testing is required) and require about 10 weeks.

Site preparation, mobilization, assembly and start-up include: shipping, receiving, off-loading, assembly, plant area preparation, electrical, plant shakedown, labor and ART management. Assembly of the plant usually requires 3 weeks. Other aspects of site preparation can be on-going as weather permits.

Operating cost includes: labor, ART management, reagents, power, water, plant feeding, excavation, backfilling. Production processing of 75,000 tons is estimated to require about 30 weeks.

Option 3 - Physical Separation with Chemical Oxidation of Sand & Fines Fraction

The proposed soil treatment process will include the same steps as for Option 2, with the difference that the fines fraction (<0.030 mm) is combined with the sand fraction prior to oxidation. The projected volume reduction and projected process product quality for this treatment option are presented in **Figure 13**. In this approach, one clean soil product will be produced.

The capital and operating cost of this plant option is estimated 5% to 10% higher than the Plant Option 2.

4.2 Plant Feed Preparation

For consistent operation of the soil treatment process, preparation of a consistent site-wide blended plant feed is required. An excavation staging and blending plan is developed prior to actual field excavation. The field implementation is performed in manageable volumes following the overall plan. For example, from one to two days of plant feed are blended at a time.

This blended feed should be consistent in terms of soil particle size, contaminant levels similar to site-wide average. In the first step of the process, soils will be pre-screened at 2” to remove coarse debris. In this pre-screening step, the soils are also blended and homogenized to provide a consistent blended feed. After pre-screening and blending, the soil is staged as feed for soil treatment processing.

The plant will be operated for 8 to 10 hours per day on a single shift, or 16 hours per day on a two-shift basis, or as operating hours allow in compliance with local governing regulations. The plant would be designed with 100% closed-loop water reuse (no normal water discharge required).

5.0 CONCLUSIONS AND RECOMMENDATIONS

Conclusions and Recommendations based on the results of this study are as follows:

- Physical Separation treatment is a viable treatment technology for TNT impacted soils at the Site. Greater than 98% of the TNT mass was removed from the sand fraction through use of water-based Physical Separation Treatment process.
- Froth Flotation (a technique widely used in mineral processing industry) was effective in removing TNT particles from the sand slurry. Density separation was tested, but not found to be effective in removing the TNT particles from either sand or oversize fractions. The density difference between TNT (specific gravity 1.8 gr/cc) and soil particles (specific gravity 2.6 gr/cc) was found to be too small to achieve a good separation.
- Grinding of the oversize to “sand size” particles and combination of the ground oversize with the sand fraction was proven to be effective treatment.
- Chemical oxidation at elevated temperature was effective in oxidizing residual TNT and DNT from sand and fines fractions; for the sand fraction TNT and DNT could be reduced to below NJDEP Non-Residential, Direct Contact Soil Remediation Standard
- Based on the results of this study, three options of soil treatment process flow diagram are proposed:

  Option 1 - Physical Separation only with oversize grinding and sand treatment using attritioning and flotation

  Option 2 - Option 1 with Chemical Oxidation of the Sand Fraction

  Option 3 - Option 2 with Chemical Oxidation of the Sand and Fines
- Combination of Physical Separation Treatment followed by natural enhanced bio-degradation is another possible treatment option. A small-scale pilot testing is suggested to generate sufficient treated soil products to evaluate combination of physical separation treatment and bio-degradation treatment.
- The design parameters of the oversize crushing, optimization of flotation contact time (kinetics) will be determined as part of the Engineering Phase.

ANALYTICAL RESULTS

Prepared by:

Eurofins Lancaster Laboratories
2425 New Holland Pike
Lancaster, PA 17601

Prepared for:

Ashland, Inc.
Bldg. 8139-48
500 Hercules Road
Wilmington DE 19808-1599

June 24, 2013

Project: Kenvil Treatability Study

Submittal Date: 06/13/2013
Group Number: 1396997
PO Number: 4501686843
Release Number: KENVIL
State of Sample Origin: NJ

Client Sample Description	Lancaster Labs (LLI) #
COMPOSITE 1 Soil Sample	7092365
COMPOSITE 2 Soil Sample	7092366
COMPOSITE 3 Soil Sample	7092367
COMPOSITE 4 Soil Sample	7092368

The specific methodologies used in obtaining the enclosed analytical results are indicated on the Laboratory Sample Analysis Record.

The LCS and/or LCSD recoveries are outside the stated QC window but within the marginal exceedance allowance of +/- 4 standard deviations as defined in the NELAC Standards. The following analytes are accepted based on this allowance:
4-Amino-2,6-dinitrotoluene
Reporting limits were raised due to interference from the sample matrix.

Wet Chemistry	**SM 2540 G-1997**		%	%	%	
00111	Moisture	n.a.	13.7	0.50	0.50	1

Moisture represents the loss in weight of the sample after oven drying at 103 - 105 degrees Celsius. The moisture result reported is on an as-received basis.

General Sample Comments

State of New Jersey Lab Certification No. PA011

All QC is compliant unless otherwise noted. Please refer to the Quality Control Summary for overall QC performance data and associated samples.

The LCS and/or LCSD recoveries are outside the stated QC window but within the marginal exceedance allowance of +/- 4 standard deviations as defined in the NELAC Standards. The following analytes are accepted based on this allowance:
4-Amino-2,6-dinitrotoluene
Reporting limits were raised due to interference from the sample matrix.

General Sample Comments

State of New Jersey Lab Certification No. PA011

All QC is compliant unless otherwise noted. Please refer to the Quality Control Summary for overall QC performance data and associated samples.

Quality Control Summary

Client Name: Ashland, Inc. Group Number: 1396997
Reported: 06/24/13 at 09:16 AM

Matrix QC may not be reported if insufficient sample or site-specific QC samples were not submitted. In these situations, to demonstrate precision and accuracy at a batch level, a LCS/LCSD was performed, unless otherwise specified in the method.

All Inorganic Initial Calibration and Continuing Calibration Blanks met acceptable method criteria unless otherwise noted on the Analysis Report.

Explanation of Symbols and Abbreviations

The following defines common symbols and abbreviations used in reporting technical data:

RL	Reporting Limit	**BMQL**	Below Minimum Quantitation Level
N.D.	none detected	**MPN**	Most Probable Number
TNTC	Too Numerous To Count	**CP Units**	cobalt-chloroplatinate units
IU	International Units	**NTU**	nephelometric turbidity units
umhos/cm	micromhos/cm	**ng**	nanogram(s)
C	degrees Celsius	**F**	degrees Fahrenheit
meq	milliequivalents	**lb.**	pound(s)
g	gram(s)	**kg**	kilogram(s)
µg	microgram(s)	**mg**	milligram(s)
mL	milliliter(s)	**L**	liter(s)
m3	cubic meter(s)	**µL**	microliter(s)
		pg/L	picogram/liter

< less than - The number following the sign is the limit of quantitation, the smallest amount of analyte which can be reliably determined using this specific test.

> greater than

J estimated value – The result is ≥ the Method Detection Limit (MDL) and < the Limit of Quantitation (LOQ).

ppm parts per million - One ppm is equivalent to one milligram per kilogram (mg/kg), or one gram per million grams. For aqueous liquids, ppm is usually taken to be equivalent to milligrams per liter (mg/l), because one liter of water has a weight very close to a kilogram. For gases or vapors, one ppm is equivalent to one microliter of gas per liter of gas.

ppb parts per billion

Dry weight basis Results printed under this heading have been adjusted for moisture content. This increases the analyte weight concentration to approximate the value present in a similar sample without moisture. All other results are reported on an as-received basis.

U.S. EPA CLP Data Qualifiers:

Organic Qualifiers

A	TIC is a possible aldol-condensation product
B	Analyte was also detected in the blank
C	Pesticide result confirmed by GC/MS
D	Compound quantitated on a diluted sample
E	Concentration exceeds the calibration range of the instrument
N	Presumptive evidence of a compound (TICs only)
P	Concentration difference between primary and confirmation columns >25%
U	Compound was not detected
X,Y,Z	Defined in case narrative

Inorganic Qualifiers

B	Value is <CRDL, but ≥IDL
E	Estimated due to interference
M	Duplicate injection precision not met
N	Spike sample not within control limits
S	Method of standard additions (MSA) used for calculation
U	Compound was not detected
W	Post digestion spike out of control limits
*****	Duplicate analysis not within control limits
+	Correlation coefficient for MSA <0.995

Analytical test results meet all requirements of NELAC unless otherwise noted under the individual analysis.

Measurement uncertainty values, as applicable, are available upon request.

Tests results relate only to the sample tested. Clients should be aware that a critical step in a chemical or microbiological analysis is the collection of the sample. Unless the sample analyzed is truly representative of the bulk of material involved, the test results will be meaningless. If you have questions regarding the proper techniques of collecting samples, please contact us. We cannot be held responsible for sample integrity, however, unless sampling has been performed by a member of our staff. This report shall not be reproduced except in full, without the written approval of the laboratory.

Times are local to the area of activity. Parameters listed in the 40 CFR part 136 Table II as “analyze immediately” are not performed within 15 minutes.

WARRANTY AND LIMITS OF LIABILITY - In accepting analytical work, we warrant the accuracy of test results for the sample as submitted. THE FOREGOING EXPRESS WARRANTY IS EXCLUSIVE AND IS GIVEN IN LIEU OF ALL OTHER WARRANTIES, EXPRESSED OR IMPLIED. WE DISCLAIM ANY OTHER WARRANTIES, EXPRESSED OR IMPLIED, INCLUDING A WARRANTY OF FITNESS FOR PARTICULAR PURPOSE AND WARRANTY OF MERCHANTABILITY. IN NO EVENT SHALL LANCASTER LABORATORIES BE LIABLE FOR INDIRECT, SPECIAL, CONSEQUENTIAL, OR INCIDENTAL DAMAGES INCLUDING, BUT NOT LIMITED TO, DAMAGES FOR LOSS OF PROFIT OR GOODWILL REGARDLESS OF (A) THE NEGLIGENCE (EITHER SOLE OR CONCURRENT) OF LANCASTER LABORATORIES AND (B) WHETHER LANCASTER LABORATORIES HAS BEEN INFORMED OF THE POSSIBILITY OF SUCH DAMAGES. We accept no legal responsibility for the purposes for which the client uses the test results. No purchase order or other order for work shall be accepted by Lancaster Laboratories which includes any conditions that vary from the Standard Terms and Conditions, and Lancaster hereby objects to any conflicting terms contained in any acceptance or order submitted by client.

Moisture represents the loss in weight of the sample after oven drying at 103 - 105 degrees Celsius. The moisture result reported is on an as-received basis.

General Sample Comments

State of New Jersey Lab Certification No. PA011

All QC is compliant unless otherwise noted. Please refer to the Quality Control Summary for overall QC performance data and associated samples.

Quality Control Summary

Client Name: Ashland, Inc. Group Number: 1400652
Reported: 07/18/13 at 12:44 PM

Matrix QC may not be reported if insufficient sample or site-specific QC samples were not submitted. In these situations, to demonstrate precision and accuracy at a batch level, a LCS/LCSD was performed, unless otherwise specified in the method.

All Inorganic Initial Calibration and Continuing Calibration Blanks met acceptable method criteria unless otherwise noted on the Analysis Report.

Explanation of Symbols and Abbreviations

The following defines common symbols and abbreviations used in reporting technical data:

RL	Reporting Limit	**BMQL**	Below Minimum Quantitation Level
N.D.	none detected	**MPN**	Most Probable Number
TNTC	Too Numerous To Count	**CP Units**	cobalt-chloroplatinate units
IU	International Units	**NTU**	nephelometric turbidity units
umhos/cm	micromhos/cm	**ng**	nanogram(s)
C	degrees Celsius	**F**	degrees Fahrenheit
meq	milliequivalents	**lb.**	pound(s)
g	gram(s)	**kg**	kilogram(s)
µg	microgram(s)	**mg**	milligram(s)
mL	milliliter(s)	**L**	liter(s)
m3	cubic meter(s)	**µL**	microliter(s)
		pg/L	picogram/liter

< less than - The number following the sign is the limit of quantitation, the smallest amount of analyte which can be reliably determined using this specific test.

> greater than

ppm parts per million - One ppm is equivalent to one milligram per kilogram (mg/kg), or one gram per million grams. For aqueous liquids, ppm is usually taken to be equivalent to milligrams per liter (mg/l), because one liter of water has a weight very close to a kilogram. For gases or vapors, one ppm is equivalent to one microliter per liter of gas.

ppb parts per billion

Dry weight basis Results printed under this heading have been adjusted for moisture content. This increases the analyte weight concentration to approximate the value present in a similar sample without moisture. All other results are reported on an as-received basis.

Data Qualifiers:

C – result confirmed by reanalysis.

J - estimated value – The result is ≥ the Method Detection Limit (MDL) and < the Limit of Quantitation (LOQ).

U.S. EPA CLP Data Qualifiers:

Organic Qualifiers		Inorganic Qualifiers	
A	TIC is a possible aldol-condensation product	**B**	Value is <CRDL, but ≥IDL
B	Analyte was also detected in the blank	**E**	Estimated due to interference
C	Pesticide result confirmed by GC/MS	**M**	Duplicate injection precision not met
D	Compound quantitated on a diluted sample	**N**	Spike sample not within control limits
E	Concentration exceeds the calibration range of the instrument	**S**	Method of standard additions (MSA) used for calculation
N	Presumptive evidence of a compound (TICs only)	**U**	Compound was not detected
P	Concentration difference between primary and confirmation columns >25%	**W**	Post digestion spike out of control limits
U	Compound was not detected	*****	Duplicate analysis not within control limits
X,Y,Z	Defined in case narrative	**+**	Correlation coefficient for MSA <0.995

Analytical test results meet all requirements of NELAC unless otherwise noted under the individual analysis.

Measurement uncertainty values, as applicable, are available upon request.

Tests results relate only to the sample tested. Clients should be aware that a critical step in a chemical or microbiological analysis is the collection of the sample. Unless the sample analyzed is truly representative of the bulk of material involved, the test results will be meaningless. If you have questions regarding the proper techniques of collecting samples, please contact us. We cannot be held responsible for sample integrity, however, unless sampling has been performed by a member of our staff. This report shall not be reproduced except in full, without the written approval of the laboratory.

Times are local to the area of activity. Parameters listed in the 40 CFR part 136 Table II as “analyze immediately” are not performed within 15 minutes.

WARRANTY AND LIMITS OF LIABILITY - In accepting analytical work, we warrant the accuracy of test results for the sample as submitted. THE FOREGOING EXPRESS WARRANTY IS EXCLUSIVE AND IS GIVEN IN LIEU OF ALL OTHER WARRANTIES, EXPRESSED OR IMPLIED. WE DISCLAIM ANY OTHER WARRANTIES, EXPRESSED OR IMPLIED, INCLUDING A WARRANTY OF FITNESS FOR PARTICULAR PURPOSE AND WARRANTY OF MERCHANTABILITY. IN NO EVENT SHALL EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL, LLC BE LIABLE FOR INDIRECT, SPECIAL, CONSEQUENTIAL, OR INCIDENTAL DAMAGES INCLUDING, BUT NOT LIMITED TO, DAMAGES FOR LOSS OF PROFIT OR GOODWILL REGARDLESS OF (A) THE NEGLIGENCE (EITHER SOLE OR CONCURRENT) OF EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL AND (B) WHETHER EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL HAS BEEN INFORMED OF THE POSSIBILITY OF SUCH DAMAGES. We accept no legal responsibility for the purposes for which the client uses the test results. No purchase order or other order for work shall be accepted by Eurofins Lancaster Laboratories Environmental which includes any conditions that vary from the Standard Terms and Conditions, and Eurofins Lancaster Laboratories Environmental hereby objects to any conflicting terms contained in any acceptance or order submitted by client.

06916	2,4,6-Trinitrotoluene	118-96-7	61,000	800	2,400	2000

Reporting limits were raised due to interference from the sample matrix.

The surrogate data is outside the QC limits due to unresolvable matrix problems evident during the sample preparation.

General Sample Comments

State of New Jersey Lab Certification No. PA011

All QC is compliant unless otherwise noted. Please refer to the Quality Control Summary for overall QC performance data and associated samples.

The recovery for a target analyte(s) in the Laboratory Control Spike(s) is outside the QC acceptance limits as noted on the QC Summary. No corrective action was taken due to the sample matrix.

The surrogate data is outside the QC limits due to unresolvable matrix problems evident during the sample preparation.

Reporting limits were raised due to interference from the sample matrix.

Quality Control Summary

Client Name: Ashland, Inc. Group Number: 1400651
Reported: 07/23/13 at 11:52 AM

Matrix QC may not be reported if insufficient sample or site-specific QC samples were not submitted. In these situations, to demonstrate precision and accuracy at a batch level, a LCS/LCSD was performed, unless otherwise specified in the method.

All Inorganic Initial Calibration and Continuing Calibration Blanks met acceptable method criteria unless otherwise noted on the Analysis Report.

Explanation of Symbols and Abbreviations

The following defines common symbols and abbreviations used in reporting technical data:

RL	Reporting Limit	**BMQL**	Below Minimum Quantitation Level
N.D.	none detected	**MPN**	Most Probable Number
TNTC	Too Numerous To Count	**CP Units**	cobalt-chloroplatinate units
IU	International Units	**NTU**	nephelometric turbidity units
umhos/cm	micromhos/cm	**ng**	nanogram(s)
C	degrees Celsius	**F**	degrees Fahrenheit
meq	milliequivalents	**lb.**	pound(s)
g	gram(s)	**kg**	kilogram(s)
µg	microgram(s)	**mg**	milligram(s)
mL	milliliter(s)	**L**	liter(s)
m3	cubic meter(s)	**µL**	microliter(s)
		pg/L	picogram/liter

< less than - The number following the sign is the limit of quantitation, the smallest amount of analyte which can be reliably determined using this specific test.

> greater than

ppm parts per million - One ppm is equivalent to one milligram per kilogram (mg/kg), or one gram per million grams. For aqueous liquids, ppm is usually taken to be equivalent to milligrams per liter (mg/l), because one liter of water has a weight very close to a kilogram. For gases or vapors, one ppm is equivalent to one microliter per liter of gas.

ppb parts per billion

Dry weight basis Results printed under this heading have been adjusted for moisture content. This increases the analyte weight concentration to approximate the value present in a similar sample without moisture. All other results are reported on an as-received basis.

Data Qualifiers:

C – result confirmed by reanalysis.

J - estimated value – The result is ≥ the Method Detection Limit (MDL) and < the Limit of Quantitation (LOQ).

U.S. EPA CLP Data Qualifiers:

Organic Qualifiers		Inorganic Qualifiers	
A	TIC is a possible aldol-condensation product	**B**	Value is <CRDL, but ≥IDL
B	Analyte was also detected in the blank	**E**	Estimated due to interference
C	Pesticide result confirmed by GC/MS	**M**	Duplicate injection precision not met
D	Compound quantitated on a diluted sample	**N**	Spike sample not within control limits
E	Concentration exceeds the calibration range of the instrument	**S**	Method of standard additions (MSA) used for calculation
N	Presumptive evidence of a compound (TICs only)	**U**	Compound was not detected
P	Concentration difference between primary and confirmation columns >25%	**W**	Post digestion spike out of control limits
U	Compound was not detected	*****	Duplicate analysis not within control limits
X,Y,Z	Defined in case narrative	**+**	Correlation coefficient for MSA <0.995

Analytical test results meet all requirements of NELAC unless otherwise noted under the individual analysis.

Measurement uncertainty values, as applicable, are available upon request.

Tests results relate only to the sample tested. Clients should be aware that a critical step in a chemical or microbiological analysis is the collection of the sample. Unless the sample analyzed is truly representative of the bulk of material involved, the test results will be meaningless. If you have questions regarding the proper techniques of collecting samples, please contact us. We cannot be held responsible for sample integrity, however, unless sampling has been performed by a member of our staff. This report shall not be reproduced except in full, without the written approval of the laboratory.

Times are local to the area of activity. Parameters listed in the 40 CFR part 136 Table II as “analyze immediately” are not performed within 15 minutes.

WARRANTY AND LIMITS OF LIABILITY - In accepting analytical work, we warrant the accuracy of test results for the sample as submitted. THE FOREGOING EXPRESS WARRANTY IS EXCLUSIVE AND IS GIVEN IN LIEU OF ALL OTHER WARRANTIES, EXPRESSED OR IMPLIED. WE DISCLAIM ANY OTHER WARRANTIES, EXPRESSED OR IMPLIED, INCLUDING A WARRANTY OF FITNESS FOR PARTICULAR PURPOSE AND WARRANTY OF MERCHANTABILITY. IN NO EVENT SHALL EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL, LLC BE LIABLE FOR INDIRECT, SPECIAL, CONSEQUENTIAL, OR INCIDENTAL DAMAGES INCLUDING, BUT NOT LIMITED TO, DAMAGES FOR LOSS OF PROFIT OR GOODWILL REGARDLESS OF (A) THE NEGLIGENCE (EITHER SOLE OR CONCURRENT) OF EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL AND (B) WHETHER EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL HAS BEEN INFORMED OF THE POSSIBILITY OF SUCH DAMAGES. We accept no legal responsibility for the purposes for which the client uses the test results. No purchase order or other order for work shall be accepted by Eurofins Lancaster Laboratories Environmental which includes any conditions that vary from the Standard Terms and Conditions, and Eurofins Lancaster Laboratories Environmental hereby objects to any conflicting terms contained in any acceptance or order submitted by client.

Quality Control Summary

Client Name: Ashland, Inc. Group Number: 1403685
Reported: 08/01/13 at 12:21 PM

Matrix QC may not be reported if insufficient sample or site-specific QC samples were not submitted. In these situations, to demonstrate precision and accuracy at a batch level, a LCS/LCSD was performed, unless otherwise specified in the method.

All Inorganic Initial Calibration and Continuing Calibration Blanks met acceptable method criteria unless otherwise noted on the Analysis Report.

Explanation of Symbols and Abbreviations

The following defines common symbols and abbreviations used in reporting technical data:

RL	Reporting Limit	**BMQL**	Below Minimum Quantitation Level
N.D.	none detected	**MPN**	Most Probable Number
TNTC	Too Numerous To Count	**CP Units**	cobalt-chloroplatinate units
IU	International Units	**NTU**	nephelometric turbidity units
umhos/cm	micromhos/cm	**ng**	nanogram(s)
C	degrees Celsius	**F**	degrees Fahrenheit
meq	milliequivalents	**lb.**	pound(s)
g	gram(s)	**kg**	kilogram(s)
µg	microgram(s)	**mg**	milligram(s)
mL	milliliter(s)	**L**	liter(s)
m3	cubic meter(s)	**µL**	microliter(s)
		pg/L	picogram/liter

< less than - The number following the sign is the limit of quantitation, the smallest amount of analyte which can be reliably determined using this specific test.

> greater than

ppm parts per million - One ppm is equivalent to one milligram per kilogram (mg/kg), or one gram per million grams. For aqueous liquids, ppm is usually taken to be equivalent to milligrams per liter (mg/l), because one liter of water has a weight very close to a kilogram. For gases or vapors, one ppm is equivalent to one microliter per liter of gas.

ppb parts per billion

Dry weight basis Results printed under this heading have been adjusted for moisture content. This increases the analyte weight concentration to approximate the value present in a similar sample without moisture. All other results are reported on an as-received basis.

Data Qualifiers:

C – result confirmed by reanalysis.

J - estimated value – The result is ≥ the Method Detection Limit (MDL) and < the Limit of Quantitation (LOQ).

U.S. EPA CLP Data Qualifiers:

Organic Qualifiers

A	TIC is a possible aldol-condensation product
B	Analyte was also detected in the blank
C	Pesticide result confirmed by GC/MS
D	Compound quantitated on a diluted sample
E	Concentration exceeds the calibration range of the instrument
N	Presumptive evidence of a compound (TICs only)
P	Concentration difference between primary and confirmation columns >25%
U	Compound was not detected
X,Y,Z	Defined in case narrative

Inorganic Qualifiers

B	Value is <CRDL, but ≥IDL
E	Estimated due to interference
M	Duplicate injection precision not met
N	Spike sample not within control limits
S	Method of standard additions (MSA) used for calculation
U	Compound was not detected
W	Post digestion spike out of control limits
*****	Duplicate analysis not within control limits
+	Correlation coefficient for MSA <0.995

Analytical test results meet all requirements of NELAC unless otherwise noted under the individual analysis.

Measurement uncertainty values, as applicable, are available upon request.

Tests results relate only to the sample tested. Clients should be aware that a critical step in a chemical or microbiological analysis is the collection of the sample. Unless the sample analyzed is truly representative of the bulk of material involved, the test results will be meaningless. If you have questions regarding the proper techniques of collecting samples, please contact us. We cannot be held responsible for sample integrity, however, unless sampling has been performed by a member of our staff. This report shall not be reproduced except in full, without the written approval of the laboratory.

Times are local to the area of activity. Parameters listed in the 40 CFR part 136 Table II as “analyze immediately” are not performed within 15 minutes.

WARRANTY AND LIMITS OF LIABILITY - In accepting analytical work, we warrant the accuracy of test results for the sample as submitted. THE FOREGOING EXPRESS WARRANTY IS EXCLUSIVE AND IS GIVEN IN LIEU OF ALL OTHER WARRANTIES, EXPRESSED OR IMPLIED. WE DISCLAIM ANY OTHER WARRANTIES, EXPRESSED OR IMPLIED, INCLUDING A WARRANTY OF FITNESS FOR PARTICULAR PURPOSE AND WARRANTY OF MERCHANTABILITY. IN NO EVENT SHALL EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL, LLC BE LIABLE FOR INDIRECT, SPECIAL, CONSEQUENTIAL, OR INCIDENTAL DAMAGES INCLUDING, BUT NOT LIMITED TO, DAMAGES FOR LOSS OF PROFIT OR GOODWILL REGARDLESS OF (A) THE NEGLIGENCE (EITHER SOLE OR CONCURRENT) OF EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL AND (B) WHETHER EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL HAS BEEN INFORMED OF THE POSSIBILITY OF SUCH DAMAGES. We accept no legal responsibility for the purposes for which the client uses the test results. No purchase order or other order for work shall be accepted by Eurofins Lancaster Laboratories Environmental which includes any conditions that vary from the Standard Terms and Conditions, and Eurofins Lancaster Laboratories Environmental hereby objects to any conflicting terms contained in any acceptance or order submitted by client.
