NOAEL	no observed adverse effects level
PAH	polycyclic aromatic hydrocarbon
PCB	polychlorinated biphenyl
PCDD	polychlorinated dibenzo-*p*-dioxin
PCDF	polychlorinated dibenzo-*p*-furan
PETN	pentaerythritol tetranitrate
RDX	royal demolition explosive (hexahydro-1,3,5-trinitro-1,3,5-triazine)
RI	remedial investigation
RIR	Remedial Investigation Report
SEL	severe effect level (sediment-specific benchmark)
SEM	simultaneously extracted metal
SI	site investigation
AUF	area use factor
SVOC	semivolatile organic compound

T&E	threatened and endangered
TNT	2,4,6-trinitrotoluene
TRSR	Technical Requirements for Site Remediation
TRV	toxicity reference value
USACE	U.S. Army Corps of Engineers
USACHPPM	U.S. Army Center for Health Promotion and Preventative Medicine
USEPA	United States Environmental Protection Agency
USFWS	U.S. Fish & Wildlife Service
VOC	volatile organic compound

Executive Summary

On behalf of Hercules LLC (Hercules), Kennedy/Jenks Consultants, Inc. (KJ) prepared this Ecological Risk Assessment (ERA) as an update to the Ecological Evaluation/ERA [2016 EE/ERA] submitted as Volume F of the May 2016 *Phase II Remedial Investigation Report* [Phase II RIR] (KJ 2016a) for the Hercules Kenvil Works Facility, located in Kenvil, Morris County, New Jersey (the Facility).

The Facility is undergoing remediation in the New Jersey Department of Environmental Protection's (NJDEP's) Contaminated Site Remediation and Redevelopment (CSRR) Program (Program Interest No. 000741) under the direction of a Licensed Site Remediation Professional (LSRP). Overall Facility remediation, including the ERA presented herein, are coordinated through the Facility's LSRP of Record (Caryn Barnes, LSRP ID No. 575011), with the NJDEP and the United States Environmental Protection Agency (USEPA). This ERA was conducted in accordance with NJDEP *Ecological Evaluation Technical Guidance* (Version 2.1; NJDEP 2023), and USEPA *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments* (1997).

Hercules' remedial strategy for the Facility remains consistent with that presented in the 2016 EE/ERA. The integration of a remedial cap in conjunction with future redevelopment across large contiguous portions of the former operational area remains a key component of the Facility's closure strategy. Hercules' 21 December 2023 remedial timeframe extension request approved by NJDEP on 11 January 2024 provides additional details related to the Facility closure strategy.

This document updates the 2016 EE/ERA and reflects current conditions and remedial status at the Facility. Updates incorporate additional data collected onsite since the 2016 EE/ERA (including that proposed in the ERA Work Plan appended to the EE/ERA at the time of submission) and is responsive to NJDEP's 2019 component review comments on the 2016 EE/ERA.

The Facility occupies approximately 1,059 acres along Howard Boulevard, about 0.5-mile northwest of the center of Kenvil, Morris County, New Jersey. Regionally, the Facility is approximately 40 miles west of New York City and 30 miles east of the Delaware Water Gap. The Facility is bounded by the New Jersey Transit Railway to the north, Berkshire Valley Road to the southeast, Route 46 to the south, and Howard Boulevard to the northwest.

The Facility began operation in 1871 and initially manufactured dynamite to support iron ore mining operations in the surrounding area. The facility was operated by various companies until 1912, when Hercules became the sole owner. Through the early and middle parts of the 20th century, Hercules expanded its manufacturing operations to meet the growing economic need for explosives and propellants. During this period, multiple operational areas were established.

Propellants and explosive and energetic (E&E) compounds, such as 2,4,6-trinitrotoluene (TNT), nitroglycerin (NG), pentaerythritol tetranitrate (PETN), smokeless powder, and ammonium nitrate fuel oil (ANFO), were produced for both military and commercial applications. Specialty products such as initiating materials, ingredients for medical applications, and materials for actuating

devices were also produced. In the final years of operation, smokeless powder was the primary product and was produced by Alliant under a site lease agreement from 1995 to 1996.

The facility ceased operation in 1996. At this time, Alliant operated the Facility, and Hercules entered into a voluntary agreement with the State of New Jersey to investigate the TNT Area. Hercules re-acquired control of the Facility on 1 January, 1997, and, as the property owner, remained responsible for remediation and closure of the Facility. Hercules, and its related environmental liabilities at the Facility, was acquired by Ashland, Inc. in 2008. Hercules currently operates as a wholly owned subsidiary of Ashland, Inc. and is responsible for remediating the Facility.

This ERA builds upon the findings presented in the media-specific Remedial Investigation Reports (RIRs) for the Facility (i.e., soil, groundwater, surface water, and sediment) and the 2016 EE/ERA and utilizes nearly 28 years of accumulated knowledge regarding historical site operations and related chemical and physical influences at the Facility.

This ERA develops a technical basis regarding whether exposure to Compounds of Potential Ecological Concern (COPECs) related to former Facility operations could adversely affect flora or fauna that inhabit the Facility. It evaluates the potential for ecological risks to ESNRs on and adjacent to the Facility consistent with NJDEP guidance (NJDEP 2023).

The site investigation/remedial investigation (SI/RI) process defined the Remedial Area based on the extent of and influences attributable to historical Facility operations and fulfilled the characterization and delineation objectives established in NJDEP's Technical Requirements for Site Remediation (TRSR). This ERA relies on the same informed, reductive approach employed in the SI/RI process and separates the Facility into three general categories described below.

- Undeveloped areas beyond the Remedial Area where the potential for ecological risk is assumed unlikely (hereafter referred to as Areas Beyond the Remedial Area Boundary).

- Areas within the Remedial Area where constituent concentrations and/or physical characteristics merit remediation (e.g., the potential for ecological risk is likely), regardless of the outcome of the EE/ERA process (hereafter referred to as Areas of Presumed Remedial Action [APRAs]).

- Areas within the Remedial Area where the potential for ecological risk is uncertain.

The first two categories represent locations where potential ecological risk is either unlikely or highly likely. These areas are discussed and considered separately and are not included in the quantitative evaluation of ecological risk for the remaining category where the potential for risk is uncertain.

The formerly developed portion of the Facility (the Remedial Area) provides patches of habitat for ecological receptors. Upper-trophic-level ecological receptors using onsite terrestrial habitats are likely to move among the habitat patches that share a common list of Facility-related constituents, as well as similarities in habitat type and composition. As such, this ERA evaluates potential exposure and risks to terrestrial receptors using one Facility-wide terrestrial soil exposure area within the Remedial Area. Acknowledging the scale of the terrestrial exposure are relative to the home ranges of certain upper trophic level receptor species, and smaller prey species, this ERA

presents an initial evaluation of localized hot spots and potential risks for COPECs identified as risk drivers.

Based on the distinct areas of surface water flow and the potential for groundwater to interact with surface water as identified during the RI, two aquatic exposure areas were identified for evaluation in the 2016 EE/ERA: Northern Drainage Area and Southern Drainage Area. These drainage areas support similar aquatic or semi-aquatic habitat, but different sources of hydrology influence these features. Discrete subdrainage areas of the Northern and Southern Drainage Areas were additionally identified based on geography, drainage pathways, and hydrological flow characteristics.

Refined subdrainage areas within the Northern Drainage Area (NDA) are identified as follows:

1. Duck Pond
2. Western Tributary
3. Unnamed Ponds
4. Northeast Ponds
5. Eastern Tributary

Refined subdrainage areas within the Southern Drainage Area (SDA) are identified as follows:

1. Central Drainage Basin
2. Development Area Stream
3. Maintenance - Dynamite Area – West
4. Maintenance – Dynamite Area – East
5. Maintenance - NG Area
6. TNT-PETN-NG Ditches
7. Miscellaneous Offsite Streams – Upper
8. Miscellaneous Offsite Streams – Lower

This ERA assesses potential ecological risk attributable to historical operational influences in formerly developed areas of the Facility. The risk characterization for lower-trophic-level receptors compares COPEC concentrations in exposure media to ecological screening benchmarks (ESBs) to generate hazard quotients (HQs). For upper-trophic-level wildlife receptors, the estimated exposure (i.e., daily dietary dose) of each COPEC to potential wildlife receptors is compared to literature-based toxicity reference values (TRVs) to generate HQs. Where applicable, a weight-of-evidence (WOE) approach considers multiple lines of evidence (LOEs) to support risk characterization and conclusions.

Potential risks to terrestrial receptors were evaluated Facility-wide. Soil COPECs, including four metals (lead, chromium, vanadium, and copper), present the highest potential for risk to terrestrial receptors via both direct exposure and food-web transfer. Metals are commonly associated with historical fill materials (e.g., fly ash, bottom ash, slag), which were byproducts of the local iron mining and processing industry and imported to the Facility as fill to support Facility development in the early 1900s. Overall, potential risks to terrestrial receptor populations related to COPECs other than lead are low.

Aquatic exposure pathways were evaluated across 13 subdrainage areas. Due to earlier development of the SDA in the Facility's history, the majority of historic fill imported to the Facility

was used to raise the ground surface elevation and support development in the SDA, and once developed, this area housed the largest concentration of historical operations and facility support services (e.g., Maintenance Area, powerhouse). These historical differences are evident in aquatic HQs from these exposure areas, as discussed below.

Four constituents (i.e., arsenic, copper, and lead) emerge as potential risk drivers in NDA subdrainage areas. Copper and lead concentrations yielded HQs greater than 1 for direct contact exposure scenarios (i.e., fish and aquatic plants and invertebrates) as well as aquatic food web modeling for upper-trophic-level mammals (i.e., little brown bat and mink). Arsenic also represents a potential risk to lower- and upper-level aquatic receptors, though elevated risk estimates are confined to the Unnamed Ponds (i.e., aquatic plants, benthic invertebrates, and little brown bat) and the Maintenance - NG Area (i.e., benthic invertebrates) and likely attributable to historical fill.

Potentially elevated risk from six COPECs (i.e., barium, cadmium, mercury, manganese, silver, and zinc), while also exceeding aquatic risk thresholds across multiple subdrainage areas, is restricted to lower-trophic-level receptors (i.e., aquatic plants and benthic invertebrates). Further, nitroglycerin presents a potential risk to piscivorous mammals (i.e., mink), though elevated risk estimates are limited to Duck Pond. Nitroglycerin is assumed to be 100% bioavailable to aquatic receptors in this ERA. In reality, nitroglycerin occurs at the Facility as a component of solid smokeless powder grains and thus is bound in an insoluble matrix with likely limited bioavailability.

Overall, Unnamed Ponds and the Eastern and Western Tributaries emerge as NDA subdrainage areas with the highest potential risk to aquatic receptors. Alternatively, potential risk to birds in each evaluated feeding guild is low in NDA subdrainage areas.

Lead, fluoranthene, and pyrene emerge as having the greatest potential for ecological risk in the SDA. Fluoranthene and pyrene are potential risk drivers to herbivorous mammals (i.e., muskrat) and piscivorous mammals (i.e., mink), while lead exceeds aquatic risk thresholds for fish, aquatic plants and invertebrates, and piscivorous mammals across several SDA subdrainage areas.

Potential risk from mercury, frequently co-located with lead, is limited to sediment direct contact in lower-trophic-level receptors (i.e., aquatic plants and benthic invertebrate communities). While bioavailability of mercury to lower-trophic-level receptors via microbial methylation is uncertain, multiple LOEs indicate potential risk to benthic invertebrates from co-located COPECs is limited to the Central Drainage Basin, Maintenance – Dynamite Area – West, and Maintenance – NG Area. While chromium exceeded HQs for lower-trophic-level receptors (i.e., benthic invertebrates and aquatic plants) in the Maintenance - Dynamite Area - East, speciation analysis indicates that sediment conditions favor the less mobile and bioavailable Cr(III).

Arsenic, copper, silver and zinc also present potential risk to lower-trophic level receptors (i.e., fish, aquatic plants and invertebrates, and benthic invertebrates) though elevated risk estimates are more limited in distribution across SDA subdrainage areas. Apart from fluoranthene and pyrene, potential risk is limited to aquatic plants, where the Central Drainage Basin, Maintenance – Dynamite Area – East and West, and Miscellaneous Offsite Streams - Lower represent the highest potential risk areas and most frequent HQ exceedances for 12 PAH congeners.

The emergence of lead to present potential risk in multiple media and exposure scenarios is not unexpected given the presence of lead in commerce, historical fill, and use of lead in historical

Facility operations. Lead used onsite existed primarily in the inorganic form, which is not readily bioavailable and not expected to bioaccumulate.

Historical fill materials were used during early development of the Facility to raise ground surface elevations. The SDA, where both PAHs and metals appear more prevalent in sediment, drains much of the former operational area of the Facility where large amounts of historical fill have been mapped (Hercules 2007, 2016). Physical and chemical conditions onsite, like those outlined above for lead, likely limit bioavailability of these potential secondary risk drivers.

The Facility history, previous reports (Hercules 2007), and Conceptual Site Model (CSM) establish links between the terrestrial and aquatic exposure areas used in this ERA. The RIRs (Hercules 2007) identified lead as a "frequent exceedance" constituent in soil, sediment, and surface water. Thus, the appearance of similar constituents (lead in particular) as potential risk drivers confirms historical findings and further informs an understanding of COPEC fate, transport, and exposure pathways.

Based on the conclusions presented above, additional ERA activities are recommended in both terrestrial and aquatic exposure areas.

Recommended action items and next steps in terrestrial exposure areas include:

1. **Spatial analysis of soil COPEC concentrations in terrestrial habitats:** To refine potential risk estimates to upper-trophic-level terrestrial receptors (i.e., short-tailed shrew and northern bobwhite), spatial analysis of soil COPEC concentrations in terrestrial habitat patches and literature-derived population density is recommended for targeted evaluation of data within home range-specific buffers for upper-trophic-level receptors.

2. **Invertebrate and plant community field evaluations in localized areas:** To further refine existing conclusions for terrestrial invertebrate and plant communities, a desktop evaluation is recommended to:

    - 1) identify habitat types in which soil COPECs disproportionately influence potential ecological risk to terrestrial plant communities, and in which terrestrial plant community surveys may be warranted, and

    - 2) identify areas of enrichment (AoEs) for four COPECs (i.e., copper, manganese, vanadium, and zinc) driving potential risk to soil invertebrates in the Facility-wide terrestrial exposure area and develop a field program to provide additional LOEs specific to these COPECs and receptors (e.g., bioavailability and toxicity). The spatial analysis (Item 1) will assist in this evaluation.

3. **Invertebrate prey tissue collection and analyses:** To further refine existing conclusions for upper-trophic-level terrestrial insectivores (i.e., American robin and short-tailed shrew), invertebrate tissue collection and analyses are recommended to provide site-specific prey tissue concentrations in terrestrial insectivore food web models (i.e., American robin and short-tailed shrew). Collection locations will be biased across the range of COPEC concentrations and informed via the results of spatial analysis recommended in Item 1.

4. No further evaluation is warranted for carnivorous bird and mammal receptors in the terrestrial exposure area.

Recommended action items and next steps in aquatic exposure areas include:

1. **Aquatic plant refined risk characterization and growth inhibition bioassays:** To further refine existing conclusions for aquatic plant communities, a stepwise evaluation is recommended to further refine aquatic plant risk characterization in various subdrainage areas. The stepwise evaluation would include a desktop evaluation of ESBs incorporating literature-derived NOEC concentrations, followed by growth inhibition bioassays of field-collected porewater in subdrainage areas where potential risk to aquatic plants remains uncertain following abovementioned desktop refinement.

2. **Sediment porewater COPEC speciation, bioavailability, and toxicity evaluations:** To further refine existing conclusions for benthic invertebrate communities, porewater sample collection is recommended to assess COPEC form, bioavailability and toxicity. Initial efforts will focus on evaluating speciation of arsenic and silver and partitioning of COPECs from sediment to porewater. If necessary, toxicity testing of field-collected porewater would be used as an additional LOE regarding potential benthic invertebrate risk from three sediment COPECs (i.e., arsenic, mercury, and silver).

3. **Desktop evaluation and aquatic invertebrate and fish habitat evaluation:** For dissolved copper, a desktop evaluation incorporating USEPA's (2007) Copper Biotic Ligand Model and site-specific water quality parameters is recommended to refine potential risk estimates to fish and aquatic invertebrates. Variations in hydrology in the Western Tributary subdrainage area throughout the seasons may preclude the ability of the habitat to sustain fish populations. To this end, a hydrology study is recommended to better align receptors with available habitat. The hydrology study could include time-series surface water sampling for total and dissolved lead and zinc to refine risk estimates for water-column invertebrates.

4. **Probabilistic risk evaluation, aquatic plant surveys, and tissue collection:** To further refine existing conclusions for herbivorous mammals in aquatic exposure areas (i.e., muskrat), aquatic vegetation surveys are recommended to delineate foraging habitat in SDA subdrainage areas. Literature-derived population density and spatial distributions of edible biomass and sediment COPEC concentrations will be incorporated in spatial analysis to evaluate probabilistic risk distributions. In subdrainage areas where risk remains uncertain following probabilistic analysis, aquatic plant tissue collection and analyses may be necessary to refine the muskrat food web model.

5. **Probabilistic risk evaluation and fish tissue collection:** For piscivorous mammals in aquatic exposure areas (i.e. mink), spatial analysis of sediment COPEC concentrations in aquatic habitat patches and literature-derived population density is recommended to evaluate probabilistic risk distributions. In subdrainage areas where risk remains uncertain following probabilistic analysis, fish tissue collection and analyses are recommended to further refine the mink food web model.

6. **Aerial invertebrate tissue collection and analyses:** For insectivorous mammals in aquatic exposure areas (i.e., little brown bat), additional aerial insect tissue collection and analyses for three COPECs (i.e., arsenic, copper, and lead) are recommended to refine insectivorous food web models for certain subdrainage areas.

Additionally, Hercules continues to advance pre-design, design, permitting, and implementation activities in APRAs identified through the RI/ERA process. Remedy selection, extents, and remediation goals will incorporate both human health and ecological endpoints and remain protective of human health and the environment. Remedial action work plans for specific APRAs will be submitted to NJDEP via e-portal, consistent with the approach taken for the TNT and PCB remedies to date.

Additional data collection is ongoing in the Areas Beyond the Remedial Area Boundary exposure area, with a sampling event scheduled for Fall 2025. Following receipt of sampling results, the ERA of this area will be updated as follows:

a) COPEC screen using the updated dataset,

b) evaluating discontinuous areas as individual exposure areas (e.g., uplands along Rt 46, western ridgeline, eastern ridgeline, northern undeveloped area),

c) assessing dataset composition (e.g., outliers) for each exposure area, and

d) providing recommendations on an area-by-area basis to address potential ecological risks (e.g., HQ>1), if identified.

Ultimately, these activities will provide a WOE approach to refine risk estimates and inform associated risk-based management decisions related to potential ecological risks at the Facility.

Section 1: Introduction

On behalf of Hercules LLC (Hercules), Kennedy/Jenks Consultants, Inc. (KJ) prepared this Ecological Risk Assessment (ERA) as an update to the Ecological Evaluation/ERA [2016 EE/ERA] submitted as Volume F of the May 2016 *Phase II Remedial Investigation Report* [Phase II RIR] (Hercules 2016a) for the Hercules Kenvil Works Facility, located in Kenvil, Morris County, New Jersey (the Facility, **Figure 1-1**). **Attachment 1** provides the 2016 EE/ERA.

The Facility is undergoing remediation in the New Jersey Department of Environmental Protection's (NJDEP's) Contaminated Site Remediation and Redevelopment (CSRR) Program (Program Interest No. 000741) under the direction of a Licensed Site Remediation Professional (LSRP). Overall Facility remediation, including the ERA presented herein, are coordinated through the Facility's LSRP of Record (Caryn Barnes, LSRP ID No. 575011), with the NJDEP and the United States Environmental Protection Agency (USEPA). This ERA was conducted in accordance with New Jersey Administrative Code (N.J.A.C.) 7:26E-4.8 Remedial Investigation of Ecological Receptors, NJDEP *Ecological Evaluation Technical Guidance* (Version 2.1; NJDEP 2023), and USEPA *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments* (1997).

Hercules' remedial strategy for the Facility remains consistent with that presented in the 2016 EE/ERA. The integration of a remedial cap in conjunction with future redevelopment across large contiguous portions of the former operational area remains a key component of the Facility's closure strategy. Hercules' 21 December 2023 remedial timeframe extension request (**Attachment 2**) approved by NJDEP on 11 January 2024 provides additional details related to the Facility closure strategy.

This document updates the 2016 EE/ERA and reflects current conditions and remedial status at the Facility. Updates incorporate additional data collected onsite since the 2016 EE/ERA (including that proposed in the ERA Work Plan appended to the EE/ERA at the time of submission) and is responsive to NJDEP's 2019 component review comments on the 2016 EE/ERA (**Attachment 3**). The regulatory chronicle that follows provides additional context and details.

1.1 Regulatory Chronicle

The 2016 Phase II RIR completed the remedial investigation (RI) phase of work at the Facility and included the 2016 EE/ERA that evaluated risk based on the comprehensive site investigation/RI (SI/RI) dataset. The 2016 EE/ERA included an ERA Work Plan outlining specific ERA desktop and field activities that would facilitate refining the risk characterization presented in the 2016 EE/ERA (Hercules 2016b). Hercules implemented the proposed activities and conducted subsequent ERA-specific field investigations between 2016 and 2019. On 8 July 2019, Hercules received NJDEP's comments on the EE/ERA submitted in May 2016 (**Attachment 3**). Hercules' ERA work completed following submission of the EE/ERA in 2016 generally aligned with and addressed certain of NJDEP's 2019 comments (**Appendix A**).

During the 2016-2019 timeframe, the Facility was being considered for redevelopment, with remedial capping over large portions of the former operational area integrated into the

development plan. Representatives from Hercules and NJDEP participated in a technical consultation on 5 December 2019 to review a revised risk characterization based on post-EE/ERA efforts, discuss incorporating development into the ERA process and build consensus on the approach to completing ERA activities for the Facility. During this meeting, Hercules and NJDEP discussed the pending development activities at the site, their influence on the ERA, and the value of defining the footprint of development (e.g., general development plan and/or site plan approval in place) prior to additional risk-related work. **Attachment 4**[1] provides the presentation from the technical consultation. Hercules agreed to prepare an ERA addendum providing data collected since the May 2016 EE/ERA and a matrix table providing the basis for identifying Areas of Presumed Remedial Action and associated status of each area as it relates to remediation and redevelopment.

In late 2020, Hercules entered into an agreement with a buyer who put forth a plan to develop an approximately 210-acre portion of the Facility where the development would remediate more than 50 percent of the AOCs onsite by functioning as a remedial cap, rendering ecological exposure pathways incomplete in that area. In August 2022, Hercules submitted a remedial action work plan for development-related capping to NJDEP; and the developer submitted development-related applications to local, county, and state agencies. As the developer engaged with various agencies (including NJDEP) reviewing permits for the proposed development, the design (including extents/footprint) was modified in response to agency feedback. As each of these changes influenced the ERA dataset, Hercules deferred completing the ERA addendum until the developer had final submissions/approvals in place that define the limits of the remedial cap and development.

At NJDEP's request, Hercules provided a development and ERA status update via email in June 2024 (**Attachment 5**). At that time, the developer was still pursuing permit approvals. Recognizing the increasing timeline for development approvals and the need to move the ERA forward in parallel, Hercules proposed to prepare an ERA data summary report without an updated risk characterization and identify how NJDEP's 2019 comments are/will be incorporated into the ERA. The ERA addendum with an updated risk characterization would follow upon receipt of development approvals that definitively establish a footprint of the development that could be relied upon in the ERA.

In August 2024, the developer walked away from the project and withdrew its development applications; Hercules also withdrew the associated remedial action work plan (**Attachment 6**).

On 30 June 2025, Hercules received an email from NJDEP directing them to submit an updated EE/ERA by 2 September 2025 (**Attachment 7**). This document is responsive to NJDEP's 2019 comments and fulfills the 30 June 2025 request. Specifically, this ERA Report:

- Presents ERA investigation findings from multiple efforts spanning 2016 to 2019 and incorporates those findings in a weight-of-evidence approach to the updated risk characterization.

[1] The underlying dataset for the statistics and visuals within this presentation may differ from this ERA report due to additional sampling and changes to APRA boundaries. This document was the basis of the conversation with NJDEP that occurred in 2019 and reflects the overall strategy/approach discussed during that meeting.

- Establishes an ERA dataset that focuses assessment activities on the biologically active zone (BAZ) in soil and sediment to the extent practicable. This approach balances the value of the breadth of historical data with the vertical intervals it represents.

- Refines risk estimates and key risk drivers in terrestrial exposure areas and proposes additional investigation activities to better align the scale of the exposure assessment with specific receptors.

- Assesses risk in a series of subdrainage areas, refining the broader drainage area approach presented in the 2016 EE/ERA and incorporating the identification and assessment of Environmentally Sensitive Natural Resources (ESNRs) at the Facility.

- Reduces the uncertainties associated with the risk characterization presented in the 2016 EE/ERA.

- Provides a forward-looking framework through which unacceptable ecological risks will be addressed.

Appendix A provides NJDEP's 8 July 2019 comments and a response matrix prepared by Hercules that illustrates how and where in this document each of the NJDEP's comments are addressed.

1.1.1 Sitewide Remedial Strategy

As part of the Remedial Agreement executed between Hercules and NJDEP in March 1995, a sitewide restoration strategy was developed to guide the investigation, remediation, and closure of the Facility. The strategy employs a phased approach whereby the focus of subsequent phases is tailored based on interpretation of information obtained during previous phase(s). The strategic approach considers both areal extent (i.e., entire Facility, former operational area, Area of Concern [AOC]) and media of interest (i.e., soil, groundwater, surface water, sediment) as appropriate. Environmental investigations at the Facility, including ERA activities, remain consistent with the Sitewide Remedial Strategy that has guided the SI/RI process, remedial action prioritization, and site closure planning to date.

The following presents an overview of investigation and assessment activities conducted in support of the ERA:

- Site Investigation – 2004
- Phase I Remedial Investigation – 2007
- Phase II Remedial Investigation – 2016
- Ecological Evaluation/Ecological Risk Assessment – 2016
- ERA Work Plan – 2016
- Terrestrial Lead Work Plan – 2018
- Updated Screening Summary & Recommendations Package – 2019
- Aquatic ERA Work Plan Addendum – 2019
- NJDEP Technical Consultation and Presentation - 2019

The 2004 SI involved a Facility-wide evaluation of environmental media (soil, groundwater, surface water, and sediment) to identify if constituents were present in media onsite, and if present, present at concentrations greater than NJDEP remedial criteria at the time. As part of the process, the SI identified approximately 1,200 AOCs at the Facility. In conjunction with NJDEP, Hercules aggregated AOCs based on proximity and/or function to develop a series of complex AOCs, called operational areas, at the scale at which remedial investigation and/or remedial action could occur. These are defined as former operational areas of the Facility (**Figure 2-2**). Collectively, these former operational areas, and certain areas immediately adjacent to them influenced by Facility operations, form the Remedial Area. The SI also evaluated whether operations influenced undeveloped areas of the Facility (i.e., those areas beyond the Remedial Area). The results of the SI focused the scope of the subsequent RI on refining the understanding of magnitude and extent, and delineating constituents in the Remedial Area. The ecological evaluation activities conducted since the 2016 EE/ERA follow this informed reductive approach in alignment with the sitewide strategy. Section 3 provides additional information regarding previous investigations at the Facility.

This document incorporates the findings presented in the 2016 Phase II RI (Hercules 2016a) and evaluates the comprehensive site characterization (SI, Phase I RI, and Phase II RI) and 2016-2019 ERA activity (as summarized in the following sections) datasets using the risk assessment framework.

1.2 Purpose and Objectives

This ERA builds upon the findings presented in the media-specific RIRs for the Facility (i.e., soil, groundwater, surface water, and sediment) and the 2016 EE/ERA, and utilizes nearly 28 years of accumulated knowledge regarding historical site operations and related chemical and physical influences at the Facility.

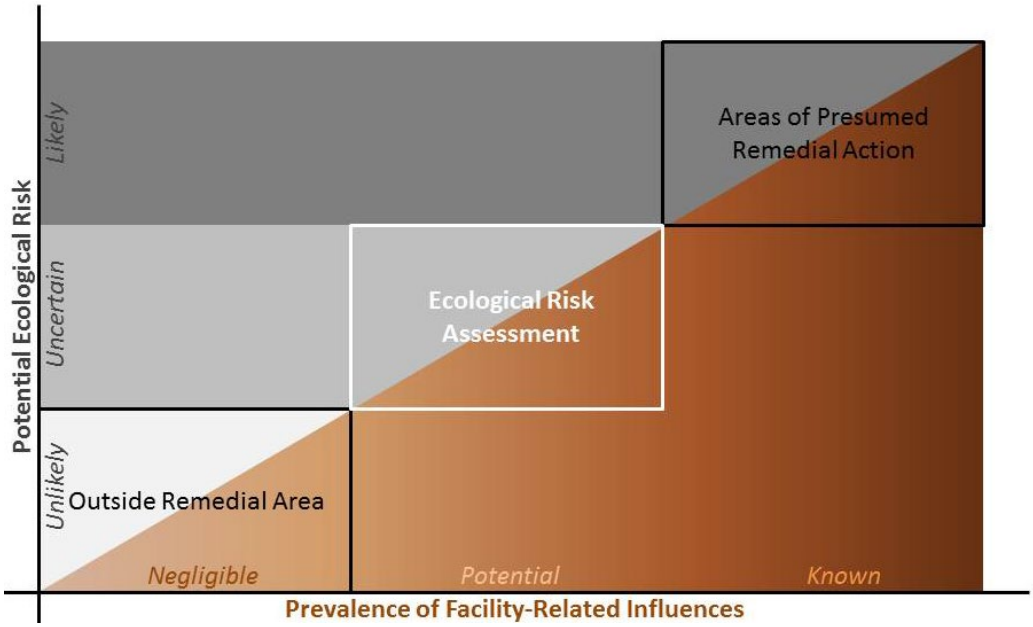
This ERA develops a technical basis regarding whether exposure to Compounds of Potential Ecological Concern (COPECs) related to former Facility operations could adversely affect flora or fauna that inhabit the site. It evaluates the potential for ecological risks to ESNRs on and adjacent to the site pursuant to NJAC 7:26E-1.16(a) and consistent with NJDEP guidance (NJDEP 2023).

The SI/RI process defined the Remedial Area based on the extent of and influences attributable to historical Facility operations. This ERA relies on the same informed, reductive approach employed in the SI/RI process and separates the Facility into three general categories described below and illustrated in the graphic that follows.

1. Undeveloped areas beyond the Remedial Area where the potential for ecological risk is assumed unlikely (hereafter referred to as Areas Beyond the Remedial Area Boundary).

2. Areas within the Remedial Area where constituent concentrations and/or physical characteristics merit remediation (e.g., the potential for ecological risk is likely), regardless of the outcome of the EE/ERA process (hereafter referred to as Areas of Presumed Remedial Action [APRAs]).

3. Areas within the Remedial Area where the potential for ecological risk is uncertain.



The first two categories represent locations where potential ecological risk is either unlikely or highly likely. These areas are discussed and considered separately and are not included in the quantitative evaluation of ecological risk for the remaining category where the potential for risk is uncertain. Additional information about Areas Beyond the Remedial Area Boundary is provided in Section 3.4. Additional information about APRAs is provided in **Appendix B**.

The overall objectives for this ERA, for the areas within the Remedial Area where the potential for ecological risk is uncertain, are as follows:

- Evaluate and present data and additional information from scientific resources to characterize ecological structure and function at the Facility.
- Describe potential ecological effects that may occur due to receptor exposure to COPECs.
- Estimate the extent of wildlife receptor exposure to COPECs.
- Characterize potential risks to wildlife receptors that may be exposed to COPECs.
- Describe uncertainty associated with the data evaluation, exposure assessment, effects evaluation, and risk characterization.
- Provide multiple lines of evidence (LOEs) to support a scientifically based risk management decision regarding the need for ecologically-focused remedial action at the Facility.

Per NJDEP and USEPA guidance, this ERA refines certain conservative assumptions from the 2016 EE/ERA using Facility-specific information and data collected between 2016 and 2019 in support of ERA and associated remedial decision-making processes. The conclusions and

recommendations of this ERA focus on additional ecological risk-related activities and/or remedial actions, where applicable.

1.3 Report Organization

The remainder of this ERA is organized as follows:

- Section 2, Facility & Environmental Background, summarizes the physical location of the Facility and its environmental chronicle.
- Section 3, Problem Formulation, describes the environmental history of the Facility, constituent releases, ecological CSM, and selects measurement endpoints (MEs) and assessment endpoints (AEs).
- Section 4, Data Review and COPEC Selection, describes data usability, the dataset used for the ERA, and screens data against ecological benchmarks to identify COPECs.
- Section 5, Ecological Exposure Assessment, discusses the selection of representative receptor species and exposure parameters used for food web modeling and presents the methodology of the food web modeling.
- Section 6, Ecological Effects Assessment, presents toxicity reference values (TRVs) for each COPEC.
- Section 7, Ecological Risk Characterization, presents results of the ERA, including hazard quotients (HQs) resulting from food web models.
- Section 8, Uncertainty Analysis, discusses specific uncertainties and their associated effects on the outcome of the ERA.
- Section 9, Recommendations, summarizes the results of the risk assessment process, including an evaluation of MEs and AEs, and provides multiple lines of evidence (LOEs) to support a scientifically-based risk management decision regarding the need for further ecological evaluation at the Facility and identify additional ERA activities to inform the need for and scope of ecologically-driven remedial actions.
- Section 10, References, lists the references used to develop this ERA.

Tables, figures, appendices, and attachments support the text and are referenced accordingly.

Section 2: Facility & Environmental Background

2.1 Facility Location

The Facility occupies approximately 1,059 acres along Howard Boulevard, about 0.5-mile northwest of the center of Kenvil, Morris County, New Jersey (**Figure 1-1**). Regionally, the Facility is approximately 40 miles west of New York City and 30 miles east of the Delaware Water Gap. The Facility is bounded by the New Jersey Transit Railway to the north, Berkshire Valley Road to the southeast, Route 46 to the south, and Howard Boulevard to the northwest. **Figure 2-1** presents a site plan with major topographic features.

2.2 Facility Development and Operations

The Facility began operation in 1871 and initially manufactured dynamite to support iron ore mining operations in the surrounding area. The facility was operated by various companies until 1912, when Hercules became the sole owner. Through the early and middle parts of the 20th century, Hercules expanded its manufacturing operations to meet the growing economic need for explosives and propellants. During this period, multiple operational areas were established (**Figure 2-2**).

Propellants and explosive and energetic (E&E) compounds, such as 2,4,6-trinitrotoluene (TNT), nitroglycerin (NG), pentaerythritol tetranitrate (PETN), smokeless powder, and ammonium nitrate fuel oil (ANFO), were produced for both military and commercial applications. Specialty products such as initiating materials, ingredients for medical applications, and materials for actuating devices were also produced. In the final years of operation, smokeless powder was the primary product and was produced by Alliant under a site lease agreement from 1995 to 1996.

The facility ceased operation in 1996. At this time, Alliant operated the Facility, and Hercules entered into a voluntary agreement with the State of New Jersey to investigate the TNT Area. Hercules re-acquired control of the Facility on 1 January 1997, and, as the property owner, remained responsible for remediation and closure of the Facility. Hercules, and its related environmental liabilities at the Facility, was acquired by Ashland, Inc. in 2008. Hercules currently operates as a wholly owned subsidiary of Ashland, Inc. and is responsible for remediating the Facility.

2.3 Environmental Chronicle

Environmental investigations were initiated onsite in response to a 1995 Remedial Agreement between NJDEP and Hercules and as part of the Industrial Site Recovery Act (ISRA) process triggered by the property transfer in 1996. The SI/RI activities spanned two decades, relied on the triad approach with NJDEP to build consensus on next steps based on the findings of prior phases of work, and culminated in the 2016 Phase II RIR documenting the completion of the RI submitted to NJDEP in May 2016. The Phase I and Phase II RIRs (Hercules 2007, 2016a) provide a comprehensive chronicle of environmental investigations conducted at the Facility and associated conclusions.

Findings from previous investigations pertinent to this ERA are summarized below.

2.3.1 Site Investigation/Remedial Investigation

In 1997, Hercules initiated an SI that included Facility-wide evaluations of environmental media (soil, groundwater, surface water, and sediment) to identify if constituents were present in media onsite, and if present, present at concentrations greater than NJDEP remedial standards at the time. As part of the process, the SI defined former operational areas of the Facility (**Figure 2-2**) and the extent of Facility operations on adjacent undeveloped areas. Collectively, these former operational areas and certain areas immediately adjacent to them influenced by Facility operations form the Remedial Area. The SI also evaluated whether operations influenced undeveloped areas of the Facility (i.e., those areas beyond the Remedial Area). The SI identified negligible influences related to Facility operations in the undeveloped areas, with the exception of a few small, isolated areas that were subsequently included in the Remedial Area and evaluated in the RI. The remaining undeveloped areas of the Facility were not evaluated further during the RI. The ERA has mirrored this approach, with a focus on the Remedial Area and a separate assessment of the undeveloped areas presented in the EE/ERA.

The results of the SI focused the scope of the subsequent RI on refining the understanding of magnitude and extent, and delineating constituents in the Remedial Area. Hercules completed the RI with the submission of the Phase II RIR in 2016. **Figure 2-2** shows the Facility boundary, Remedial Area, and former operational areas.

Regulatory submissions associated with the SI/RI are summarized in the following table.

Date	Report
May 2004	*Site Investigation Report – Soil* (MWH Americas Inc. [MWH] 2004a)
November 2004	*Site Investigation Report – Sediment/Surface Water* (MWH 2004b)
July 2005	*Site Investigation Report - Groundwater* (MWH 2005a)
May 2005	*Area I Remedial Investigation Work Plan* (MWH 2005b)
December 2006	*Revised Site-Wide Remedial Investigation Work Plan* (MWH 2006)
May 2007	*Phase I Remedial Investigation Report* [Phase I RIR] (MWH 2007)
April 2016	*Phase II RIR* (Hercules 2016a), including EE/ERA (Volume F) and *ERA Work Plan* (2016 ERAWP)

As excerpted from the Phase II RIR, *the principal findings of the SI and RI performed at the Facility include:*

- *The intent of the N.J.A.C. 7:26E TRSR for remedial investigations [N.J.A.C. 7:26E – 4.1 through 4.8] has been met. Facility-related influences in environmental media (soil, groundwater, sediment, and surface water) have been delineated site-wide.*

- *The SI and RI combine to effectively characterize and delineate the nature and extent of Facility-related influences. Influences associated with former manufacturing operations were often comingled with those attributable to the use of historic fill during Facility development. Where practicable, these influences have been separated and constituent sources identified.*

- *Facility-related influences in environmental media result in unacceptable levels of potential risk to ecological receptors based on the screening and conservative exposure modeling conducted in the EE/ERA. In response to these findings, additional sampling has been proposed to generate Facility-specific data that will replace non-specific estimated concentrations in the exposure models. The refined risk analysis will identify discrete areas of the Facility driving these risk estimates, and inform the remedial decision-making process related to these areas as well as the overall Facility. Establishment of ecological-based remediation goals will incorporate the footprint of redevelopment and related future land uses.*

- *Current Facility use precludes human health exposure risks, as personnel permitted to access the Facility are trained in the identification and control/mitigation of potential exposures. Characterization and delineation did not identify Facility-related influences beyond the property boundaries. As such, no off-site human health exposure risks exist.*

- *The SI and RI generated sufficient information to identify and prioritize areas requiring administrative controls and/or active remediation. These administrative controls and remedies will be aligned with redevelopment planning.*

Hercules continues to design and implement remedial actions focused on areas identified in the RI, including those APRAs identified in the EE/ERA.

2.3.2 ERA Activities – 2016 to 2019

The 2016 EE/ERA concluded that:

- Overall, the potential for ecological risks is low.

- The greatest potential for adverse effects is from lead. Upper-trophic-level receptors in terrestrial and aquatic exposure areas exhibit elevated lead HQs.

- Risk characterization also identified other metals and polycyclic aromatic hydrocarbons (PAHs) as the COPECs that pose the potential to cause adverse effects to ecological receptors exposed to environmental media at the Facility.

- Risk characterization relied on conservative exposure assumptions and did not incorporate measures of COPEC bioavailability. Soil and sediment characteristics at the Facility allow for the sequestration and binding of metals and PAHs, potentially reducing the fraction of these COPECs available for uptake by receptors and reducing the potential for adverse effects.

Based on the results presented in the 2016 EE/ERA and the uncertainty regarding bioavailability, additional risk assessment activities at the Facility to refine the risk characterization were recommended and presented in the ERAWP provided as an appendix to the 2016 EE/ERA. The ERAWP included spatial analysis to refine the scale at which exposures areas evaluated risk, with additional data collected recommended to refine exposure estimates.

Following submission of the 2016 EE/ERA, Hercules implemented the ERAWP and built upon the findings of that work through a series of documents focused on refining risk estimates, identifying areas requiring remediation based (in whole or in part) on ecological risk, and considering future development in the ERA process.

ERA-related documents prepared following ERAWP implementation are summarized in the following table.

Date	Attachment	Record Item
December 2018	**Attachment 8**	*Terrestrial Lead Work Plan* [2018 TLWP]
March 2019	**Attachment 9**	*Updated Screening Summary & Recommendations Package* [SSRP]
June 2019	**Attachment 10**	*Aquatic Ecological Risk Assessment Supplemental Sampling Memo* [Aquatic ERASSM]
December 2019	**Attachment 4**[2]	NJDEP Technical Consultation Presentation

The narrative that follows summarizes the scope and objectives associated with these documents within the context of the aquatic and terrestrial risk characterization that they refined.

The ERAWP (Hercules 2016b), developed as an appendix to the 2016 EE/ERA (**Attachment 1**), presented a desktop evaluation that refined the results of the 2016 EE/ERA. Specifically, this evaluation:

- Modified area use factors (AUFs) of upper-trophic level receptors, conservatively set at 1 in the 2016 EE/ERA, to reflect species-specific migratory patterns and home ranges from USEPA (1993)
- Updated dietary composition to reflect information available from species-specific field studies presented by USEPA (1993) and Hansen (2011).
- Preferentially selected TRVs based on species-specific studies of wild (rather than domesticated/lab-raised) individuals presented in USEPA documents and/or peer-reviewed scientific literature.
- Identified fractional risk contributions from distinct subareas composing the larger aquatic exposure areas.

The ERAWP desktop evaluation focused on refining understanding of potential impact to receptors by identifying those COPECs most likely to present unacceptable risk. Based on these findings, the ERAWP concluded that:

- **Terrestrial evaluation:** Additional evaluation of the form(s) and speciation of lead was needed better understand and assess its potential bioavailability to the American robin (*Turdus migratorius*).

[2] The underlying dataset for the statistics and visuals within this presentation may differ from this ERA report due to additional sampling and changes to APRA boundaries. This document was the basis of the conversation with NJDEP that occurred in 2019 and reflects the overall strategy/approach discussed during that meeting.

- **Aquatic evaluation:** Additional evaluation of sediment and surface water and aerial insect tissue sample collection was needed within distinct subareas of aquatic exposure areas to validate and refine modeled dietary exposures.

The following sections summarize the concurrent timeline of aquatic and terrestrial ERA activities following EE/ERA submission.

2.3.2.1 Aquatic Characterization

The 2007 Phase I Remedial Investigation Report – Volume B – Soil (Phase I Soil RIR; Hercules, 2007) identified changes in hydrology resulting from demolition and site investigation activities. Specifically, the removal of over 1,000,000 square feet of impervious surfaces and more than 325 buildings reduced the overland flow of stormwater that was managed via a series of ditches and channels. Following demolition, the upper ends of these ditches no longer received runoff, conveyed water, or supported aquatic receptor communities. As such, sediment samples in these reaches were re-categorized as soil samples and evaluated relative to soil criteria (Section 2.4 of the Phase I Soil RIR).

KJ observed continued changes in the upper reaches of certain ditches during ERAWP implementation activities in aquatic exposure areas in June 2016. Based on these observations, a survey of the historical drainage ditches evaluated in the EE/ERA was conducted in 2017 to identify reaches that no longer provide aquatic habitat or provide limited aquatic habitat (as discussed further in Section 3.2.1.1). Consistent with the approach taken during the Phase I RI, additional sediment samples in the reaches that no longer provided aquatic habitat were reclassified as soil and evaluated as part of the terrestrial exposure assessment. Recent observations did not identify further changes to the hydrology; conditions appear stable and additional substantive changes to these feature classifications are not expected.

Sediment data collected during ERAWP implementation were screened to evaluate potential risks of COPECs to ecological receptors (i.e., benthic invertebrate communities). The results of this screening, the survey to refine the sediment dataset, and resulting recommendations were documented in the March 2019 Updated SSRP (**Attachment 9**). The Updated SSRP recommended supplemental sampling in seven subdrainage areas to further evaluate potential risk to benthic macroinvertebrate communities in these areas.

The Aquatic ERASSM (**Attachment 10**) outlined proposed supplemental sampling activities as recommended in the Updated SSRP. The objectives of the Aquatic ERASSM field sampling plan were as follows:

- Evaluate bioavailability of divalent metals (i.e., copper, cadmium, lead, nickel, and zinc) and chemical speciation of chromium in subdrainage area sediment via analyses of acid-volatile sulfide/simultaneously extracted metals (AVS/SEM), hexavalent chromium, and sediment chemistry and grain size.

- Evaluate bioavailability of polycyclic aromatic hydrocarbons (PAHs) in subdrainage area sediment via analyses of 34 parent PAHs and alkylated families (USEPA Method 8270SIM) and equilibrium-partitioning sediment benchmark toxic units (ESBTUs)

- Evaluate the form and bioavailability of mercury in subdrainage area surface water via analysis of total and dissolved methylmercury (USEPA Method 1630)

- Evaluate benthic invertebrate community composition and diversity in subdrainage areas via benthic invertebrate community surveys in target subdrainage areas and reference areas

Aquatic ERASSM implementation occurred in August 2019 (**Appendix C**), results of which were presented to NJDEP during the 2019 Technical Consultation (Section 2.3.2.3).

Additionally, an updated survey of freshwater wetlands and/or State open waters was conducted at the Facility from 2018 to 2020 for the purpose of permitting ongoing site remediation and long-term site redevelopment activities. A Freshwater Wetlands Letter of Interpretation (LOI) Line Verification application was submitted to the NJDEP Division of Land Resource Protection on 2 November 2020 and approved by NJDEP on 27 August 2021. These surveys of aquatic and transitional habitat are incorporated into the ERA (Section 3.2.1).

2.3.2.2 Terrestrial Characterization

The 2018 TLWP (**Attachment 8**) outlined data collection activities to refine existing conclusions regarding lead in Facility soil and its potential risk to terrestrial receptors (i.e., American Robin). The objectives of the TLWP were as follows:

- Identify lead concentrations in the terrestrial exposure area driving risk estimates (areas of enrichment [AoEs]).
- Develop conceptual site models (CSMs) for each AoE.
- Establish a sampling plan to evaluate bioavailability, chemical speciation, and physical form of lead in soil of AoEs and the potential for upper trophic level receptor prey items to bioaccumulate lead.

KJ implemented TLWP field sampling activities in December 2018 (as detailed further in **Appendix D**), results of which were presented to NJDEP during the 2019 Technical Consultation (as discussed further in the following section).

2.3.2.3 2019 Technical Consultation and Presentation

Representatives of Hercules and NJDEP met for a technical consultation on 5 December 2019 (KJ 2020a). The objectives of the technical consultation included:

- Discuss NJDEP's 8 July 2019 Ecological Component Review comments,
- Update NJDEP on supplemental ERA activities and remediation activities that occurred between May 2016 to December 2019, and
- Initiate an ongoing dialogue between NJDEP and Hercules to build consensus on the approach to completing EE/ERA activities for the Facility.

During this technical consultation, Hercules representatives presented the results of supplemental ERA desktop and field activities implemented per the ERAWP, TLWP, and ERASSM (a copy of the presentation is provided in **Attachment 4**); and agreed to submit an ERA addendum incorporating these results and NJDEP comments into the ERA (the ERA Addendum was

subsequently deferred due to changes in the redevelopment plans). Hercules also informed NJDEP that development planning at the Facility was underway and would fundamentally influence ecological exposure pathways onsite in terrestrial and aquatic exposure areas. Additional details related to development planning, and its influence on the ERA, are provided in Section 2.3.4.

2.3.3 Remedial Actions

Concurrent with completing the RI via submission of the 2016 Phase II RIR, Hercules initiated planning and design activities associated with remedial actions in certain "Areas of Presumed Remedial Action" [APRAs] (e.g., TNT Area). Additionally, the conclusions of the RI and EE/ERA identified additional areas that merit remediation (e.g., Maintenance Area PCBs). Brief summaries of key remedial actions completed and underway are provided below. Additional information can be found in **Table 2-1**, **Attachment 2** and at www.hercules-kenvil.com.

Between 2017 and 2022, Hercules designed, permitted and implemented remedial excavation of soil containing PCBs and lead in the Maintenance Area, and soil containing PCBs in a northeast portion of the Development Area (AOC M5-3). These removals resulted in the offsite disposal of approximately 13,000 tons of regulated waste. A remedial cap compliant with NJDEP and Toxic Substances Control Act specifications will be integrated into site development design and documented in a remedial action report following construction completion.

From 2013 to present, Hercules has designed, piloted, permitted, and is implementing a multi-year soil bioremediation project addressing TNT in soil in the southwestern portion of the Facility (KJ 2020b). The remedy will treat approximately 100,000 tons of soil via a sequential ex-situ and in-situ bioremediation process, eliminating the need to transport contaminated soil offsite and providing for the use of treated (remediated) soil as backfill in the excavation areas.

Hercules continues to advance the design and implementation of pre-design investigations and remedial actions in APRAs. **Appendix B** presents information specific to each APRA and chronicles progress toward completing remedies for each area.

2.3.4 Facility Redevelopment

Future use at the Facility is considered in remedial action objectives and incorporated into the design, ultimately positioning the Facility for reuse. While no current development plan exists, future uses based on zoning designations for the Facility may include a mixture of preserved open space and light industrial/ commercial development.

Hercules, Roxbury Township, the New Jersey Highlands Council, and the New Jersey Office of Smart Growth developed conceptual future use plans for the Facility. Following cessation of operations in 1996 and throughout the decommissioning and environmental investigation process, the future use plans focused redevelopment in the central core of the Facility, in areas corresponding to those previously developed for Facility operations (**Figure 2-2**). The wetland complex at the southern end of the Facility, as well as Duck Pond and the forested area to the north, remain undeveloped as natural open space (**Figure 2-3**). Similarly, the steep wooded ridgelines that bound the Facility remain primarily undeveloped.

Hercules continues to develop a remedial strategy for the Facility that positions portions of the former operational areas for redevelopment while preserving the Facility's natural resources. This approach aligns with the brownfields redevelopment concept, best management practices (e.g., low-impact development and stormwater management), NJDEP land use practices, conceptual development plans prepared by Roxbury Township, and infrastructure already in place to support redevelopment (e.g., transit station, heavy rail access, water and wastewater resources).

In November 2020, Hercules entered into a sales agreement with a prospective buyer. Shortly thereafter the buyer engaged with regulatory agencies (local, county, state) and initiated design and pursuit of development-related approvals. The initial design focused on approximately 210-acre portion of the Facility where the development would remediate more than 50 percent of the AOCs onsite by functioning as a remedial cap rendering ecological exposure pathways incomplete. As the developer engaged with various agencies (including NJDEP) reviewing permits for the proposed development, the design (including extents/footprint) was modified in response to agency feedback. Hercules deferred ERA-related work until the developer had final submissions/approvals in place that define the limits of the remedial cap and development.

In August 2024, the developer walked away from the project and withdrew its development applications; Hercules also withdrew the associated remedial action work plan. Hercules is currently evaluating other prospective buyers and associated conceptual development plans.

The ERA presented herein addresses the entirety of the former operational area at the Facility. The integration of remedial capping into a development plan for the Facility remains the presumptive remedy for the central portion of the Facility where historic fill and operational influences are widespread in soil. Development-related influences on the ERA risk characterization will be addressed in future deliverable(s) as appropriate based on development planning and approval timelines.

2.4 Ecology

2.4.1 Regional Ecology

The Facility is located in the New Jersey Highlands physiographic province of north-central New Jersey and is characterized by broad, elevated ridges separated by long, narrow valleys. In general, topographic features in this region (e.g., ridges and valleys) tend to be oriented in a southwest to northeast direction (**Figure 2-1**).

Preserved land, primarily upland deciduous forest (dry mesic mixed oak forest [Karlin 1989]), is relatively abundant near the Facility. Rock outcrops, forested wetland mosaics, and stream channels intersperse among the expanses of upland forest. Open space within approximately 10 miles from the site includes the Berkshire Valley Wildlife Management Area, Mahlon-Dickerson Reservation, Allamuchy State Park, and other smaller parcels. Dense commercial and residential development and major infrastructure routes (e.g., railroads and highways) fragment other areas of forest habitat into smaller isolated patches.

The area currently known as Morris County was subject to repeated glaciation. Glacial lakes of varying sizes (e.g., Longwood Lake, Lake Hopatcong) occur in areas around the Facility. The glaciers scoured the northern part of the county to bare rock in places, deposited glacially mixed

till, transported material over the county, and altered drainage patterns. Included within the formerly glaciated areas are numerous kettles, or basins. These kettles were filled progressively as organic material and mineral sediment accumulated in them. These features occur in the northeastern portion of the Facility (Natural Resources Conservation Service 1976) beyond the former operational footprint.

Roxbury Township and Morris County support light industrial/commercial development. Originally settled in the early 1700s, Morris County became a national leader in iron ore mining following the Revolutionary War. By the late 1800s, the county produced more than ½ million tons of iron ore and relied on forests to provide wood and the vast network of flowing streams to power the mills and forges. By the early 1900s, the mining industry moved toward the Great Lakes region and the county became a suburban center for New York City. Consequently, this dynamic development history altered the landscape, ecology, and hydrology. Mapping and assessment (at the HUC-14 level) conducted by the New Jersey Highlands Council identifies the effect of these changes on the Facility's subwatershed, and others in the surrounding area, by assigning a moderate resource value (NJDEP 2024).

2.4.2 Local Ecology

The Facility is situated on a valley floor between two forested ridgelines. The former Facility operational areas remain vacant following decommissioning and demolition activities conducted between 1996 and 2003. These areas are in various states of vegetation succession and currently exist primarily as grass field and shrublands, interspersed with remnant infrastructure and building remains.

Transit corridors and development adjacent to the Facility create ecological breaks, separating the Facility from other natural areas nearby. Smaller ecological receptor species are unlikely to cross these ecological breaks and thus exist at the Facility in the capacity that the Facility is capable of supporting them. Given the size of the Facility and range of habitat and forage sources it provides, the Facility is likely to support populations of smaller receptor species. Larger, upper-trophic-level species are less restricted by these ecological breaks, particularly avian species that cover large areas to forage and/or breed.

Hydrologic inputs at the Facility consist of precipitation, surface water features, stormwater from adjacent developed areas, and other flow conveyed by natural, altered, and man-made features. Remnants of the stormwater management systems in place during historical Facility operations serve to drain and convey stormwater onsite. The area north of Powder Mill Road near the construction and demolition debris landfill (C&D landfill) serves as a general topographic and flow divide. Water entering the Facility via streams, runoff, and stormwater outfalls south of the C&D landfill is conveyed through a series of culverts and ditches to the wetland complex at the southern end of the Facility. Duck Pond (and vernal pools to a lesser extent) serves as the collection point for sources of hydrology north and east of the divide, including a series of wetlands and tributaries draining directly to Duck Pond. These systems were mapped and modeled as part of the July 2021 Flood Hazard Area Verification issued by NJDEP associated with the TNT soil bioremediation project currently underway.

Section 3: Problem Formulation

3.1 Environmental History

Historically, the valley currently occupied by the Facility drained the neighboring ridgelines via a network of wetlands and streams. Development and expansion occurred periodically throughout the Facility history and made use of historic fill materials (e.g., fly ash, bottom ash, and slag derived from the combustion of coal), obtained primarily from offsite sources. Fill was used to raise ground surface elevations, provide a stable substrate for transportation and operational infrastructure (i.e., narrow gauge rail, roadways, buildings) and otherwise manage or direct surface water (i.e., stormwater runoff, historical drainage features).

Multiple production/operational areas supported former operations at the Facility (**Figure 2-2**). Initial operations involved the manufacture of dynamite (NG encased with absorptive filler material in a waxed paper shell) to support local iron ore mining. The original dynamite production area was located within a small section of the later developed NG, TNT, and Dynamite Areas identified on **Figure 2-2**. Portions of the later developed A-Line and Maintenance Areas were also used for finished product storage (A-Line) and maintenance activities (Maintenance Area).

Demand for E&E products increased during war time (beginning with World War I and continuing through the Vietnam War). In response, manufacturing operations expanded to encompass approximately 800 acres, including the PETN, A-Line, B-Line, ammonium nitrate (AN), Finishing, Storage, Development, and Diazo (diazodinitrophenol) Areas. Support areas were also developed, including office space, plant laboratories, maintenance areas, power houses, mixed acid areas, drum storage areas, the water supply system, a wastewater treatment plant, warehouses, and miscellaneous production and support buildings.

Figure 2-2 provides approximate boundaries for former operational areas of the Facility.

3.1.1 Environmental Releases

Environmental releases occurred during the operational history and, to a lesser extent, during historical demolition practices (e.g. burning structures in place). Releases included accidents and/or incidents during production and transport of materials throughout the Facility as well as influences from historical practices onsite. Release mechanisms (e.g., fires, explosions, spills) and notable events are described below.

3.1.1.1 Fires

Historically, fires occurred as accidents and a means of intentionally decontaminating structures contaminated with E&E constituents or destroying off-specification E&E products. Uncontrolled fires resulting from accidents and production upsets were most frequent from 1871 until the 1950s when more advanced manufacturing process controls were incorporated. Though less common, fires have been documented as recently as 1989. Fires were of critical concern for the Facility as the nature of the E&E constituents manufactured released tremendous energy that could result in multiple operations becoming involved prior to the fire becoming controlled and eliminated.

Fires resulting from both accidents and intentional thermal decontamination efforts required the use of significant quantities of water. Accidental fires were contained and extinguished as soon as possible with as much water as could be directed toward the fire. There are no records of the use, storage, manufacturing, or handling of per- and polyfluoroalkylated substances related to fire suppression or other activities at the Facility. Intentional thermal decontamination efforts required the use of significant quantities of water to ensure the fire did not spread beyond the intended structure. The water used had the potential to redistribute constituents either not consumed or affected by fire creating localized heterogeneity of constituent distribution.

In some instances, it is possible that not all combustible constituents, including E&E, are consumed by fire. Small-scale detonations can occur if E&E constituents detonate at their thermal decomposition temperature of if they are confined with sufficient pressure. These small-scale detonations can cause the material to be thrown away from the fire and not be consumed. Certain energetic constituents have high melting and decomposition temperatures and have the potential to migrate in the molten state and recrystallize when temperatures drop below their melting point.

3.1.1.2 Explosions

Historically explosions at the Facility were not uncommon occurrences. In particular, during the World War I (WW I) era as many as 6,000 marginally trained and educated employees were imported from around the country to meet the rapidly increasing need for E&E constituents required to supply the United States (US) and its allies (Great Britain, France, and Russia). Other peak war time production eras (WW II, Korea, and Vietnam) also incorporated large untrained work forces into an ever-increasing production demand. Correspondingly, an increase in explosions occurred.

In most cases explosions were limited to single operational units (e.g., C13 – 666 Refined TNT Graining House), and while the explosions were very destructive. They were limited in the extent of their effect. Explosions resulted in disturbed ground surface, shattered structures, and scattered debris. Along with these direct effects, explosions also represent a potential means of constituent release and distribution.

3.1.1.3 Spills

Throughout the more than 125 years of manufacturing history at the Facility, general operations had the potential to release constituents to the environment through accidents (other than the more destructive fires and explosions previously discussed) or spills on relatively small scales.

Accidents during transportation of raw and finished products have the greatest potential to release constituents to the environment. Transportation of raw and finished products was accomplished through a variety of methods that included: mule-drawn buggies, human-drawn buggies (angel buggies), narrow gauge rail, and trucks. A small percentage of the accidents may have involved a release of the transported materials. Spillage of materials can occur for a variety of reasons that are often precipitated by either mechanical failure or human error.

It is possible that to a small degree some of the localized heterogeneity within the former operational areas of the Facility where material handling occurred could be attributed to the release of constituents by accidents and spills.

3.1.1.4 Historic Fill

The Facility began as a small operation in 1871 and solely produced dynamite to support the local iron mining industry. Manufacturing activities were limited to the southwestern area of the Facility in a small section of the current NG, TNT, and Dynamite Areas. Operations are believed to have been limited to the higher topography of the western ridge or immediately adjacent to the ridge where wet areas were not present. Portions of the A-Line and Maintenance Areas were also used in support roles such as finished product storage (A-Line) and maintenance activities (Maintenance Area). These areas were either located on the western ridge, adjacent to the western ridge, or on well drained elevated ground.

In the years leading up to and including WW I, the need for explosives and propellants increased dramatically and Hercules greatly expanded its manufacturing operations. Prior to this expansion, it is believed surface elevations in many portions of the Facility were in close proximity to the water table and unsuitable for industrial development. Historic fill (consisting of fly ash, bottom ash, and slag derived from the combustion of coal) largely imported from off-site sources, was used to increase grade, eliminate shallow ponds/wet areas, improve drainage, and increase compatibility of the soils to allow construction of large manufacturing complexes. Historic fill was also used extensively for establishing both narrow gauge and standard gauge rail beds. In addition to rail beds, historic fill was used in some locations as part of the bridging support material used to allow narrow gauge rail lines to cross the numerous shallow streams located in the southwestern portion of the facility. Narrow gauge rail was the primary vehicular conveyance system at the Facility for more than 75 years and is substantially smaller than standard gauge rail, allowing it to be moved or redirected quickly to meet changing operational needs. Due to the unknown historical topography of the Facility (e.g. location of former ponds/wet areas) and the locations of temporary narrow-gauge railbeds over time, the distribution of the historic fill is widespread and heterogeneously distributed across the Facility.

Hercules imported potentially large quantities of historic fill from local available sources that are believed to have possessed metal and PAH constituents prior to entering the Facility. The former iron foundries located in Dover, New Jersey, approximately four miles east of the Facility, are thought to have been the primary source of historic fill based on their location and extensive use of coal, although documentation of the source is not available.

Due to the very short period (1912 to 1914) of the large-scale Facility expansion, other unknown sources of historic fill may have been secured. It is likely that historic fill from on-site Facility boilers[3] were added to the imported historic fill but represented a very small fraction of the total historic fill emplaced.

[3] The Facility is believed to have possessed a total of four powerhouse sites with associated coal-fired boilers that supported previous manufacturing operations. Prior to the large WWI expansion, the powerhouses were relatively small (typically two boilers per powerhouse) and provided steam for areas immediately adjacent to the individual powerhouses. The small powerhouses were in the Dynamite, NG, Storage, and Maintenance former operational areas. The Maintenance Area powerhouse was divided into two structures, each believed to have two boilers. A total of ten small boilers are believed to have been present at the Facility prior to the WWI expansion. The exact dates of construction or operation of the four small power houses are not known but may have extended from the late 1800s through WWI (1919). Following WWI and after the major Facility expansion was complete the four small boilers were dismantled and replaced by a single large central powerhouse in the Maintenance Area that produced both steam and electricity.

3.2 Ecological Conceptual Site Model

Facility development, operations, and operational incidents served as historical sources and distributive processes by which constituents entered environmental media (primarily soil) at the Facility. The import of historic fill materials in the early 1900s, as well as precipitation and stormwater runoff draining from adjacent areas to the Facility, provide additional historical and current constituent sources. Time and natural processes (e.g., erosion, sorption, degradation) influence the distribution of constituents within soil, as well as from soil to secondary and tertiary media (e.g., groundwater, surface water, sediment, and biological tissue). As Facility operations changed over time, these distributive processes changed and altered the conditions in which potential exposures could occur.

Over the past 20 years, conditions onsite have remained stable. Localized areas have been disturbed and subsequently restored as part of remedial actions.

3.2.1 Habitat Characterization

The characterization of on-site and adjacent habitats provides information used to refine potential exposure and migration pathways and inform the selection of exposure areas and receptor species used in the ERA activities chronicled in this document. To this end, field surveys were conducted on 28 to 30 July 2010 that characterized aquatic, terrestrial, and wetland habitats (**Table 3-1**) and identified wildlife in these areas (**Table 3-2**). Additionally, data were collected from May through July 2011 during a Site-wide wetlands assessment (as detailed further in Section 3.2.1.1). The following information was collected in each habitat, as appropriate:

- Location and approximate boundaries
- Vegetative community structure and composition
- Hydrologic influences

Habitat designations were assigned to each habitat identified in the field surveys based on the Checklist for Ecological Assessment/Sampling, which is included in the *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments* (USEPA 1997). Ecosystem type designations included the following: terrestrial wooded, terrestrial scrub/shrub, terrestrial open field, terrestrial miscellaneous, aquatic non-flowing, aquatic flowing, and wetlands (**Figure 2-3**).

The presence of wildlife was identified via individual sightings, audible calls, or visual observation of wildlife signs (e.g. tracks, nesting structures, scat, and den sites). Rocks, logs, and leaf litter were also temporarily overturned to look for wildlife, such as amphibians, reptiles, and small mammals. Wildlife survey data (identification to lowest taxon, sighting type, notable observations) were recorded in a field log book and documented with digital photographs when possible (**Table 3-2**).

As part of the ERA update, the information presented in the 2016 EE/ERA was reviewed and updated to incorporate more recent and detailed information and more accurately reflect current Facility conditions, including ecosystems and presence of wildlife. Information sources include:

- Stream hydrology assessment in 2017

- Flood Hazard Area Verification mapping in 2019
- Wetland surveys between 2018 and 2020 and NJDEP's associated line verification work in 2021, and
- Current New Jersey Natural Heritage (NHP) Database and NJDEP Landscape Project (Version 3.3)

Beyond these formal assessments and surveys, remedial activities (ERA and otherwise) and development planning have resulted in field ecologists spending substantive amounts of time (e.g., more than 10,000 hours) onsite throughout the seasons since 2020. Qualitative ecological observations made over time by field teams (e.g., wildlife use, hydrological conditions, habitat variations) are incorporated into the information used in the development of this ERA.

3.2.1.1 Stream Hydrology Assessment

Stream reaches were originally mapped and classified during the SI, and mapping was based in part on historical Facility drawings. Following the SI, demolition of the Facility altered drainage patterns and removed some areas of impermeable surface cover. In light of these changes, a survey of stream reaches and hydrology during the RI resulted in the re-classification of certain SI sediment samples as soil samples based on then-current stream hydrology. In the time that has passed since the RI, vegetative succession has occurred, further reducing surface water runoff that feeds many of the water features onsite.

As summarized in the previous section, an updated survey of drainage features was conducted at the Facility in 2017 during ERAWP implementation to identify stream segments that no longer provide aquatic or transitional habitat.

Figure 3-1 illustrates the results of the 2017 survey and identifies stream segments as flowing, dry, or intermittent. Sediment and soil datasets reflect these updated hydrologic conditions; samples collected in areas identified as flowing or intermittent are incorporated in the sediment dataset, and samples collected in areas identified as dry are incorporated in the soil dataset.

3.2.1.2 Wetland Delineation

Hercules delineated wetlands at the Facility in 1999, following cessation of operations and prior to the majority of demolition activities onsite. The series of ditches and culverts that managed stormwater runoff during the Facility's operations remained largely intact at this time. Demolition and remediation activities removed areas of impervious surface, altered stormwater runoff patterns and volumes, and resulted in microtopographic alterations (e.g., ruts, grading following building slab removal).

A 2011 wetland delineation identified wetland conditions that formed after the 1999 delineation throughout the formerly developed core of the Facility (primarily the Maintenance Area, Diazo Area and A Line) as a result of hydrology and topography changes attributable to demolition and remediation activities. Unmaintained drainage pathways (i.e., clogged/damaged culvert pipes) also caused other upland areas of the Facility to hold water and wetland conditions to establish.

Following the 2011 wetland delineation, ongoing vegetative succession further decreased runoff volumes and maintenance of drainage pathways restored stormwater drainage patterns and eliminated ponding.

In anticipation of permitting multiple remedial actions and in support of development planning, Hercules conducted a formal wetland delineation and applied for a freshwater wetlands Letter of Interpretation (LOI) Line Verification in 2020. The delineation was conducted pursuant to the Freshwater Wetlands Protection Act (N.J.S.A. 13:9B-1 et seq.) and consistent with Federal Interagency Committee for Wetland Delineation (FICWD) *Federal Manual for Identifying and Delineating Jurisdictional Wetlands* (FICWD 1989) and the *Eastern Mountains and Piedmont Regional Supplement* (USACOE 2012), an updated survey of freshwater wetlands and/or State open waters was conducted at the Facility from 2018 to 2020 for the purposes of permitting for ongoing site remediation and long-term site redevelopment activities.

NJDEP issued the LOI for the Facility on 27 August 2021 (File No. 1400-20-003.2**)**. Pursuant to N.J.A.C 7:7A-4.6, this LOI approval remains valid through August 2026.

Figure 2-3 illustrates the current wetland delineation. Historical sediment and soil datasets have been revised to reflect these updated hydrologic conditions.

3.2.1.3 New Jersey Natural Heritage Database Search

An updated search of the NHP Database was requested in 2025 to identify documented records of rare animals, plants, and natural communities at the Facility and/or within 0.25 miles of the Facility. Database results were received on 11 August 2025 and are provided in **Attachment 11**.

The NJ NHP identified records of the following state or federal threatened or endangered species, or their habitat and feature type, on the Facility:

- Arogos skipper (*Atrytone arogos*) – state endangered, nectaring/breeding/courtship
- Red-shouldered hawk (*Buteo lineatus*) – state endangered, breeding
- Bobcat (*Lynx rufus*) – state endangered, sighting
- Northern myotis (*Myotis septentrionalis*) – federally listed threatened, sighting
- Indiana bat (*Myotis sodalis*) – federally listed endangered, state endangered, sighting

According to the database, Downy phlox (*Phlox polisa var. pilosa* [state endangered plant]) was identified onsite in 1937. Downy phlox has not been observed during various ecological surveys conducted at the Facility.

The following vernal pool habitat record was also identified on the Facility:

- Potential vernal habitat area (Vernal Pool Habitat ID: 2622)

In addition to the records onsite, the search results also identified records of the following threatened or endangered species or their habitat within 0.25 miles of the Facility:

- Little brown bat (*Myotis lucifugus*) – state endangered
- Tricolored bat (*Perimyotis subflavus*) – state endangered

- Barred owl (*Strix varia*) – state threatened
- Golden-winged warbler (*Vermivore chrysoptera*) – state endangered
- Bog turtle (*Glyptemys muhlenbergii*) – federally listed threatened, state endangered
- Wood turtle (*Glyptemys insculpta*) – state threatened

The following vernal pool habitat records were also within 0.25 miles of the Facility:

- Vernal habitat area (Vernal Pool Habitat IDs: 2622, 2641, 2710)
- Potential vernal habitat area (Vernal Pool Habitat ID: 182)

Information provided by the NJ NHP relies on records of documented occurrences and information contained in the NJDEP Landscape Project (Version 3.3) map. The Landscape Project mapping uses buffers representative of foraging ranges or other species-specific behaviors (i.e. migration) and mapped habitat types to develop areas considered potential habitat for the species in question. NJDEP Landscape Project (Version 3.3) maps confirm the NJ NHP results (**Attachment 7**).

With the exception of an encounter with a rabid bobcat onsite in November 2017[4], none of the threatened or endangered species listed as possibly present on-Site have been identified on-Site. With the exception of the bog turtle, species-specific surveys have not been conducted.

3.2.1.3.1 Bog Turtle Habitat

Hercules conducted a bog turtle habitat assessment at the Facility in Fall 2014. A Phase 1 Bog Turtle Habitat Assessment Report identifying eight (8) survey areas within delineated wetlands that contained potential habitat for bog turtle (Maser 2017). These findings are reflected in the wetland resource value classification issued by NJDEP in the 2021 LOI.

3.2.2 Environmentally Sensitive Natural Resources

Ecological CSM development, including identification of ESNRs, incorporates Facility-specific knowledge and experience, and information from NJDEP's NJ-GeoWeb and the NJ Natural Heritage Program (NHP).

ESNRs are defined in the *Technical Requirements for Site Remediation* (N.J.A.C 7:26E-1.8) as all areas specified in *Discharges of Petroleum and Other Hazardous Substances Rules* (N.J.A.C. 7:1E-1.8) (environmentally sensitive areas), groundwater, and areas and/or resources that are protected or managed pursuant to the Pinelands Protection Act and the Pinelands Comprehensive Management Plan[5]. Environmentally sensitive areas may include but are not limited to the following:

1. Surface waters, including rivers, streams, creeks, ponds, lakes, reservoirs, canals, estuaries, open bays, semi-enclosed bays, and back bays

[4] This case was reported to NJ Fish & Wildlife (File No. 17-1109094427).
[5] The Facility is not located in an area regulated by the Pinelands Protection Act or associated management plan.

2. Wetlands and wetland transition areas, including associated buffers,
3. Any water resource utilized by a public or nonpublic water system,
4. Bay islands and barrier island corridors,
5. Beaches and dunes,
6. Critical wildlife habitat and/or habitat for Federal and State endangered or threatened plant and animal species,
7. Prime fishing areas, finfish migratory pathways, and/or shellfish waters,
8. Submerged vegetation habitat,
9. Prime or unique forestland, and
10. Federal and State wilderness areas, and
11. Wild and scenic river corridors.

3.2.2.1 Summary of ESNRs Identified

ESNRs identified at, or adjacent to, the Facility are detailed Section 3.2.1, shown on the habitat map (**Figure 2-3**), and summarized as follows:

- Surface waters
    - Unnamed tributaries flowing on the Facility through the Northwestern Development Area.
    - Unnamed tributary system flowing on the Facility from the Southern Maintenance Area south through the Dynamite Area and miscellaneous/offsite areas.
    - Duck Pond
    - Shooting Pond
    - Unnamed ponds southeast of Duck Pond
- Wetlands and wetland transition areas, including submerged vegetation habitat
    - Emergent wetlands in the Southern Maintenance Area and along the border of the NG and Dynamite Areas. Emergent wetlands are also interspersed on-Site in sunny open areas of the Site, some depressional areas formed during remedial activities, and open water fringe areas.
    - Forested wetland patches in the Dynamite Area, south of the Dynamite Area within the miscellaneous/offsite areas, and the northeastern-most part of the Facility, B-Line Area southeast of Duck Pond, Development Area northwest of Duck Pond, and Northeast and Northwest Storage Areas.

  - A series of isolated wetlands and vernal pools located in the Northern Drainage Area.

- Suitable habitat for threatened and endangered species
  - On-Site: red-shouldered hawk, arogos skipper, bobcat, bog turtle, Indiana bat, and northern myotis
  - Adjacent: bald eagle, barred owl, golden-winged warbler, bog turtle, and wood turtle

- State Open Space
  - The Berkshire Valley State Wildlife Management Area (WMA) located north of the Facility on the other side of Interstate 80 and Norfolk Southern rail corridors.

The following ESNRs were not identified at, or adjacent to, the Facility:

- Water resources utilized by a public or nonpublic water system,
- Bay islands or barrier island corridors,
- Beaches or dunes,
- Critical wildlife habitat
- Prime fishing areas, finfish migratory pathways, or shellfish waters,
- Prime or unique forestland, or
- Wild and scenic river corridors

3.2.3 Groundwater

While not a direct ecological exposure medium, groundwater may serve as a potential transport medium of COPECs from source release areas. As detailed in Section 3.2.3.3, groundwater quality is well-defined and, with exception to a TNT plume in the southwestern corner of the Facility, largely unaffected by historical operations. This ERA characterizes potential ecological risk related to groundwater via surface water and sediment aquatic receptors in the Facility.

3.2.4 Exposure Areas

Results of SI/RI data collection as well as the habitat characterization, described in Section 2.3.1 supported the development of exposure areas. Exposure areas for the ERA built upon the Facility-specific 2016 EE/ERA approach described in Section 2.3.2. The 2016 EE/ERA initially separated the Facility into three general categories:

- Areas where ecological risk is negligible.
- Areas where ecological risk is uncertain and assessment is needed.

- Areas where constituent concentrations and/or physical characteristics merit remediation (e.g., ecological risk likely), regardless of the outcome of the ecological risk assessment process (APRAs).

The purpose of this approach was to focus the 2016 EE/ERA on areas where risks may be present and avoid confounding the process by evaluating areas where risks are unlikely (undeveloped areas beyond the Remedial Area) or very likely (APRAs), or where proposed remedial actions will address any potential exposure risks (APRAs).

By eliminating areas beyond the influences of historical Facility operations based on previous investigation results (e.g., areas beyond the Remedial Area) and areas where active remediation or removal will occur (APRAs), the exposure areas selected below represent portions of the Remedial Area of the Facility where the potential for ecological risk remains uncertain.

The remainder of this document focuses on these areas of uncertainty within the Remedial Area. The 2016 EE/ERA included a separate assessment of the undeveloped areas beyond the Remedial Area, and this area is discussed further in Section 9 of this ERA.

Terrestrial and aquatic exposure areas are discussed below and presented in **Figures 3-1 and 3-2**, respectively.

3.2.4.1 Terrestrial Exposure Area

The formerly developed portion of the Facility (the Remedial Area) provides patches of habitat for ecological receptors. Upper-trophic-level ecological receptors using onsite terrestrial habitats are likely to move among the habitat patches that share a common list of Facility-related constituents, as well as similarities in habitat type and composition. As such, this ERA evaluates potential exposure and risks to terrestrial receptors using one Facility-wide terrestrial soil exposure area within the Remedial Area (**Figure 3-2**).

Acknowledging the scale of the terrestrial exposure are relative to the home ranges of certain upper trophic level receptor species, and smaller prey species, Section 9 presents an initial evaluation of localized hot spots and potential risks for COPECs identified as risk drivers.

Similarly, terrestrial habitat exists beyond the Remedial Area and is assessed separately. The EE/ERA includes an ERA of the undeveloped areas surrounding the Remedial Area. This area is also addressed further in Section 9.

3.2.4.2 Aquatic Exposure Areas

Based on the distinct areas of surface water flow and the potential for groundwater to interact with surface water as identified during the RI, two aquatic exposure areas were identified for evaluation in the 2016 EE/ERA: Northern Drainage Area (NDA) and Southern Drainage Area [SDA] (**Figure 3-1**). These drainage areas support similar aquatic or semi-aquatic habitat, but different sources of hydrology influence these features (as detailed in the following sections).

Discrete subdrainage areas of the NDA and SDA were identified based on geography, drainage pathways, and hydrological flow characteristics. These refined aquatic exposure areas are shown in **Figure 3-1** and discussed in the following sections.

3.2.4.2.1 Northern Drainage Area

This drainage area consists of aquatic features located north and east of the small stream channel described in the following section. Duck Pond serves as the primary drainage feature in the NDA, receiving water from surrounding stream channels, wetlands, and Shooting Pond. A series of isolated wetlands and vernal pools also exist in the NDA (**Figure 2-3**). The NDA occurs almost entirely within the Remedial Area boundary; samples collected from an isolated pond that borders the Remedial Area were also included in the NDA.

Refined subdrainage areas within the NDA are shown in **Figure 3-1** and identified as follows:

1. Duck Pond
2. Western Tributary
3. Unnamed Ponds
4. Northeast Ponds
5. Eastern Tributary

3.2.4.2.2 Southern Drainage Area

Surface water enters the Facility via a small stream channel along the northwestern Facility boundary, near the intersection of Howard Boulevard and Interstate 80. The stream, referred to as the development stream, flows southwest before entering a culvert beneath Powder Mill Road and discharges to the southern wetland complex. Overland flow and surface water runoff generally follow the same pattern, draining to aquatic features and flowing to the southern end of the Facility via a series of ditches and swales. These drainage features and the receiving waters of the southern wetland complex make up the SDA.

The SDA captures the water bodies within the Remedial Area as well as the series of ditches that drain the southern wetland complex south of the Remedial Area boundary. These ditches receive surface water and suspended sediment from the southern wetland complex (within the Remedial Area boundary) that drains former operational areas of the Facility. These drainage channels also receive runoff from Howard Boulevard and Route 46. Ultimately the wetland complex drains to a single tributary that flows offsite at the southeastern corner of the Facility. Data from 2013 sampling at and proximate to this outlet indicate that Facility-related influences cease upstream of the outlet, thus the exposure area does not extend offsite.

Refined subdrainage areas within the SDA are shown in **Figure 3-1** and identified as follows:

1. Central Drainage Basin
2. Development Area Stream
3. Maintenance - Dynamite Area – West
4. Maintenance – Dynamite Area – East

5. Maintenance - NG Area
6. TNT-PETN-NG Ditches
7. Miscellaneous Offsite Streams – Upper
8. Miscellaneous Offsite Streams – Lower

3.2.4.2.2.1 NG Area-Former Ponds

The NG Area – Former Ponds are remnant stormwater management features that occupy an area at the base of the hillside on which the NG and PETN production lines sat.

Additional environmental investigation was proposed to occur in the former ponds during the TLWP implementation in 2018. Habitat characterization efforts between 2016 and 2020 have established the former ponds as terrestrial habitat and the data have been reclassified as soil and this area is now designated an APRA due to high concentrations of lead in soil (as detailed further in Section 3.4.1)

3.2.4.3 Groundwater

Groundwater quality at the Facility is well defined and stable over time. Given the long industrial history of the Facility, groundwater is largely unaffected by historic site operations (Hercules 2007, 2009, 2016c), with the exception of a TNT plume in the southwestern corner of the Facility. TNT is observed in groundwater in proximity to the southern wetland complex (Miscellaneous Offsite Steams – Lower), however, the influences of TNT in groundwater are not observed in surface-water and sediment in this area of the Facility.

Regional groundwater issues do have the potential to affect surface water and sediment quality at the Facility. For example, NJDEP, in cooperation with Hercules, evaluated a regional tetrachloroethene (TCE) groundwater plume adjacent to the Facility. They found that while the Facility falls within the footprint of the TCE plume, the Facility was not a contributor to the plume (Hercules 2007). However, the interaction between groundwater underlying the Facility and various surface water features (e.g., wetlands, ponds, ditches) represents a potential migration pathway for constituents unrelated to the Facility.

Ecological receptors are exposed to constituents in groundwater via groundwater discharges to surface-water features. As such, evaluating surface water and sediment characterizes potential ecological risk related to groundwater for aquatic receptors at the Facility.

3.2.4.4 Potential Ecological Receptors

Potential ecological receptors onsite and in the surrounding environment can be directly or indirectly exposed to constituents in environmental media if a complete exposure pathway exists.

Ecological receptor groups potentially exposed to constituents in terrestrial areas of the Facility include:

- Terrestrial plants
- Soil-dwelling invertebrates
- Mammals with terrestrial-based diets
- Birds with terrestrial-based diets

Ecological receptors potentially exposed to constituents in aquatic areas of the Facility include:

- Benthic invertebrates
- Aquatic plants
- Water column invertebrates
- Fish
- Mammals with aquatic-based diets
- Birds with aquatic-based diets

Specific receptors are selected to represent the organisms that could be present most frequently or are likely to be sensitive to the effects of constituents in environmental media. Selection considerations include the following factors:

- Occurrence of potentially complete pathways for exposure of ecological receptors to constituents in environmental media
- Resident communities or species exposed to the highest concentrations of constituents in environmental media
- Species or functional groups considered to be essential to, or indicative of, the normal functioning of the affected habitat
- Species of special status or designation (e.g., threatened or endangered) by state or federal entities
- Feasibility of completing a quantitative assessment for the identified pathways and receptors (e.g., availability of modeling parameters and toxicology values)

Based on the above criteria, the following ecological receptor populations and associated feeding guilds (where applicable) are evaluated in this ERA:

- Terrestrial Area:
    - Terrestrial plant communities
    - Terrestrial invertebrate communities
    - Insectivorous mammals (short-tailed shrew [*Blarina brevicauda*])
    - Insectivorous birds (American robin [*Turdus migratorius*])

- Herbivorous birds (northern bobwhite [*Colinus virginianus*])
- Herbivorous mammals (white-tailed deer [*Odocoileus virginianus*])
- Carnivorous birds (red-tailed hawk [*Buteo jamaicensis*])
- Carnivorous mammals (red fox [*Vulpes vulpes*])

- Aquatic Area:
  - Benthic invertebrate communities
  - Aquatic plant communities
  - Fish and aquatic invertebrate communities
  - Piscivorous mammals (mink [*Neovison vison*])
  - Piscivorous birds (great blue heron [*Ardea herodias*])
  - Herbivorous birds (mallard duck [*Anas platyrhynchos*])
  - Herbivorous mammals (muskrat [*Ondatra zibethicus*])
  - Insectivorous birds (tree swallow [*Tachycineta bicolor*])
  - Insectivorous mammals (little brown bat [*Myotis lucifugus*])

3.2.4.5 Potential Ecological Exposure Pathways

Potential ecological receptors onsite and in the surrounding environment can be directly or indirectly exposed to constituents in environmental media if a complete exposure pathway exists. An exposure pathway is considered complete if it contains the following five elements:

- Constituent source
- Release mechanism to the environment
- Transport medium
- Receptor contact at the exposure point
- Exposure route.

Important considerations when evaluating exposure pathway completeness include:

- Constituent concentrations in different media and their respective locations
- Physical and chemical properties of Facility-related constituents
- Locations of environmentally sensitive areas.

Potentially complete exposure pathways for each medium are discussed in the following sections. A graphical ecological CSM showing potential media, pathways, and ecological receptors is provided on **Figure 3-3**.

3.2.4.5.1 Surface Soil

Potential exposure routes associated with surface soil[6] include direct contact, ingestion, inhalation, and indirect exposure (i.e., food-web transfer). Constituents in soil possess varying degrees of potential for exposure through each of these exposure routes depending on chemical-specific parameters. The following potentially complete exposure pathways to surface soil were identified:

- Incidental contact with constituents in soil (i.e., dermal exposure) by plants and soil invertebrates is a complete exposure pathway. Plants and soil invertebrates are directly exposed to constituents from the soil. This pathway is quantitatively evaluated comparing soil constituent concentrations to soil ecological screening benchmarks[7] (ESBs) protective of plants and soil invertebrates (Section 5.1).
    - Ingestion of constituents in soil by plants and soil invertebrates is a complete exposure pathway. Plants and soil invertebrates may directly ingest constituents from the soil. This pathway is quantitatively evaluated by comparing soil constituent concentrations to soil ESBs (Section 5.1).
    - Indirect exposure to soil via food-web transfer of bioaccumulative constituents is a complete exposure pathway for upper-trophic level wildlife receptors (i.e., birds and mammals). Bioaccumulative constituents taken up by soil invertebrates and plants may be consumed by mammalian and avian wildlife as part of their diets. This pathway is quantitatively evaluated via food web modeling (Section 5.1.2).
    - Incidental ingestion of contaminated soil by upper-trophic level wildlife (i.e., birds and mammals) is a complete exposure pathway. Wildlife may indirectly ingest constituents from soil during foraging. This pathway is quantitatively evaluated via food web modeling (Section 5.1.2).
    - Incidental contact with constituents in soil (i.e., dermal exposure) by wildlife is a potentially complete exposure pathway. Wildlife may have direct exposure to soil while burrowing and/or preening; however, because fur or feathers greatly reduce the potential exposure, direct contact with soil is considered a minor, *de minimis* pathway for wildlife and is not evaluated quantitatively (Suter 2007).
    - Inhalation of constituents in soil by wildlife, via inhalation of airborne soil particulates or volatilization of constituents from the soil, is a potentially compete exposure pathway. However, inhalation as a route of exposure is likely to be insignificant compared to other routes of exposure for two reasons:
        - Vegetative cover would prevent substantial production of airborne particulates due to wind erosion.
    - Most Facility-related constituents in soil are unlikely to volatilize from the soil due to their physicochemical properties. Those constituents that may volatilize are unlikely to be present in substantial concentrations following volatilization and subsequent dispersal. As

[6] This ERA evaluates a surface soil sample as a soil sample with a starting depth from 0 to 0.5 foot below ground surface (bgs) and an end depth no more than 1.5 feet bgs. This evaluation accounts for the size and variability of the SI/RI dataset and includes sample intervals spanning the biologically active zone (BAZ).

[7] Ecological screening benchmarks were selected from NJDEP's Ecological Screening Criteria (ESC) table (NJDEP 2009) and supplemented with preferentially selected ESBs from based on a review of appropriate ecological literature (Section 4.2.1).

a result, the inhalation pathway is considered insignificant (Suter 2007) and is not quantitatively evaluated.

3.2.4.5.2 Surface Water

Direct contact with surface water represents a potentially complete exposure pathway for both aquatic and terrestrial receptors. Aquatic receptors such as fish and water column invertebrates may be directly exposed to constituents in surface water via ingestion and direct contact/uptake. Exposure to surface water is evaluated by comparing surface water ESBs that are protective of aquatic life to surface water data.

Upper-trophic level aquatic and terrestrial wildlife receptors may ingest surface water; however, surface water ingestion represents a *de minimis* exposure pathway for constituents, when compared to wildlife exposure via ingestion of dietary food items, soil and/or sediment. As such, the surface water ingestion pathway for wildlife receptors is not quantitatively evaluated.

3.2.4.5.3 Surface Sediment

Surface sediment represents the primary medium for aquatic receptor exposure to constituents. Exposure to sediment occurs in the BAZ, which is identified based on levels of dissolved oxygen, bioturbation, and other biological processes (Interstate Technology & Regulatory Council [ITRC] 2011). Ecological receptors may be exposed to constituents in surface sediment via three potential routes of exposure: direct contact, ingestion, and food-web transfer. The potential completeness of each of these exposure pathways is evaluated below:

- Direct contact with constituents bound to sediment is a potentially complete exposure pathway for aquatic plants and benthic invertebrates. Constituents bound to sediment and those dissolved in the interstitial water (pore water) of the sediment can affect aquatic plants and invertebrates through dermal contact and absorption into tissues. This pathway is quantitatively evaluated by comparing sediment constituent concentrations to ESBs protective of plants and benthic invertebrates (Section 5.1).
- Ingestion of constituents bound to sediment is a potentially complete exposure pathway for aquatic plants and benthic invertebrates. Constituents bound to ingested sediment and in pore water may partition into invertebrate tissues through the lining of the digestive tract and via root uptake into aquatic plants. This pathway is quantitatively evaluated by comparing sediment constituent concentrations to sediment ESBs protective of aquatic plants and benthic invertebrates (Section 5.1).
- Food-web transfer of constituents bound to sediment is a complete exposure pathway for upper-trophic level wildlife consumers. Constituents can accumulate in tissues of lower-trophic level aquatic organisms (e.g., benthic organisms, fish, aquatic plants), which are then consumed by avian and mammalian receptors. This pathway is quantitatively evaluated via food web modeling (Section 5.1).
- Ingestion of sediment containing COPECs is a complete exposure pathway for upper-trophic level wildlife (i.e., birds and mammals). Wildlife may indirectly ingest constituents from sediment during foraging. This pathway is quantitatively evaluated via food web modeling (Section 5.1.2).

3.3 Assessment and Measurement Endpoints

AEs provide explicit expressions of the actual environmental values (i.e., ecological resources) that are to be protected at the Facility (USEPA 1997) and are based on the complete exposure pathways and receptor categories identified in the CSM. Four principal criteria are used to select ecological values that may be appropriate for use as AEs (USEPA 1998a):

1. Ecological relevance
2. Susceptibility to known or potential stressors
3. Commercial or social value
4. Relevance to management goals

AEs focus risk assessment on components that could be adversely affected by COPECs at a site. AEs are typically communities or trophic guilds (e.g., insectivorous birds). Trophic guilds may be deemed at risk if statistically significant, population-level effects occur to reproduction or survival of a receptor species representing the subject trophic guild.

Population-level effects of concern include:

- Mortality, growth, or reproductive effects resulting from direct exposure to constituents that may result in population-level effects.
- Mortality, growth, or reproductive effects resulting from exposure to constituents that have bioaccumulated in the food web and may result in effects to trophic-level receptor populations.
- Indirect effects associated with a substantial reduction in abundance of prey populations.

MEs are characteristics, quantifiable through laboratory or field experimentation, that are related to the valued characteristic chosen as the AE (USEPA 1992a, 1998a). The ME represents the same exposure pathway and mechanisms of toxicity as the associated AE.

Based on the complete exposure pathways and potential receptor categories identified at the Facility, the following AEs and MEs were identified for each of the selected receptor groups (**Table 3-3**). The AEs are phrased as risk questions and the MEs were selected to address these questions, as presented below.

Terrestrial Area

AE 1. Could direct contact with COPECs in Facility soil affect the structure, function, and/or survival of the terrestrial plant community?

- ME 1. Compare concentrations of COPECs in soil to ESBs protective of terrestrial plants.

AE 2. Could direct contact with COPECs in Facility soil affect the structure, function, and/or survival of the terrestrial invertebrate community?

- ME 2. Compare concentrations of COPECs in soil to ESBs protective of terrestrial invertebrates.

AE 3. Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of herbivorous avian and mammal populations?

- ME 3. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for herbivorous birds and mammals (represented by northern bobwhite and white-tailed deer).

AE 4. Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of insectivorous avian and mammal populations?

- ME 4. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for insectivorous birds and mammals (represented by American robin and short-tailed shrew).

AE 5. Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of carnivorous avian and mammal populations?

- ME 5. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for carnivorous birds and mammals (represented by red-tailed hawk and red fox).

Aquatic Areas

AE 6. Could direct contact with COPECs in sediment in each area affect the structure, function, and/or survival of the benthic invertebrate community?

- ME 6. Compare COPEC concentrations in sediment in five (5) NDA and eight (8) SDA subdrainage areas to ESBs protective of benthic invertebrates.

AE 7. Could direct contact with COPECs in sediment in each area affect the survival and function of aquatic plant populations?

- ME 7. Compare COPEC concentrations in sediment in five (5) NDA and eight (8) SDA subdrainage areas to ESBs protective of terrestrial plants.

AE 8. Could direct contact with COPECs in surface water in each area affect the survival and reproduction of fish and aquatic invertebrate populations?

- ME 8. Compare COPEC concentrations in surface water in five (5) NDA and eight (8) SDA subdrainage areas to ESBs protective of fish and aquatic invertebrates.

AE 9. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of herbivorous avian and mammal populations?

- ME 9. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for herbivorous birds and mammals (represented by mallard duck and muskrat) in five (5) NDA and eight (8) SDA subdrainage areas.

AE 10. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of insectivorous avian and mammal populations?

- ME 10. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for insectivorous birds and mammals (represented by tree swallow and little brown bat) in five (5) NDA and eight (8) SDA subdrainage areas.

AE 11. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of piscivorous avian and mammalian populations?

- ME 11. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for piscivorous birds and mammals (represented by great blue heron and mink) in five (5) NDA and eight (8) SDA subdrainage areas.

3.4 Excluded Areas

As discussed, areas of the Facility where potential ecological risk is either likely (e.g., APRAs) or unlikely (areas beyond the Remedial Area) are not evaluated in this ERA.

3.4.1 Areas of Presumed Remedial Action

Based on a review of the CSM, historical Facility information, and current analytical data, several process/disposal areas within the Remedial Area were identified as areas where remedial action is warranted, irrespective of the outcome of the ERA. The locations, composition, and/or constituents present in these areas align with historical Facility practices and records from the Facility (e.g., disposal areas, explosions).

Appendix B presents a description of each APRA, including the presumptive remedial approach protective of human health and the environment and anticipated implementation timeline. APRAs are also listed in the table below.

Area of Presumed Remedial Action
TNT Area - TNT Soil Bioremediation Project Area
Ammonium Nitrate Area – Former Burning Ground and Intervening AOCs
B-Line Area – WWII Disposal Area (M8-1)
Development Area – Old Burning Grounds (M5-3 and AOCs to the Southwest)
Storage Area – WWI Disposal Area (N6-1)
B-Line Area – South (conglomerate of AOCs)
A-Line Area – Northwest (conglomerate of AOCs)
Development Area – Ballistics Range
Development Area - Experimental Dynamite Production Area
PETN/NG Area – Acid Recovery
Maintenance Area – PCBs
Maintenance Area – Acid Production Plant
NG Area – Former Ponds

Acknowledging the pending remedial actions in these APRAs, data from these areas are not included in this ERA. **Table 2-1** provides information regarding the history, constituent fate and transport, and presumptive remedy for each area. **Figure 3-2** notes these areas on a site plan.

3.4.2 Areas Beyond the Remedial Area Boundary

The SI/RI identified the Remedial Area by comparing sample results from undeveloped areas around the margins of the Facility to criteria protective of human health (i.e., soil remediation goals). Once established, additional site characterization activities focused on the Remedial Area. This ERA relies on the Remedial Area to focus assessment activities. As part of establishing the assessment area, sample results from undeveloped areas around the margins of the Facility (outside the Remedial Area) were evaluated in the context of potential ecological risk as a technical appendix to the 2016 EE/ERA. The evaluation concluded that potential ecological risk in the undeveloped areas beyond the Remedial Area is unlikely.

3.4.3 Summary

This ERA uses data collected as part of site characterization activities. Where potential ecological risk is likely (APRAs), Hercules is committed to active remediation and focusing efforts on remedial planning. Acknowledging undeveloped areas of the Facility beyond the influence of former operations (i.e., beyond the Remedial Area boundary) allows the evaluation to focus on the remaining areas of the Facility where potential ecological risk is uncertain.

Section 4: Data Review and COPEC Selection

Information in the following sections describes the data available from previous investigations and ERA activities, and data consolidation procedures used in the ERA. The data were then compared to literature-based ecological screening benchmarks (ESBs) to identify COPECs for quantitative evaluation in the ERA.

4.1 Data Usability

The SI/RI dataset was reviewed for applicability to the ERA. Data collected as part of the SI and Phase I RI were validated by a third-party validator in accordance with USEPA's Region II Standard Operating Procedures (SOPs) for data validation (USEPA 2022b).

The quality of the data was assessed according to USEPA's PARCC (precision, accuracy, representativeness, comparability and completeness) parameters. These criteria were used to identify unacceptable or biased data that could result in corrective actions being implemented or otherwise require qualification of the data. Reporting limits provided by the laboratory were elevated if the sample was analyzed at a dilution; however, data were not qualified based on elevated reporting limits. The evaluation of the data against PARCC criteria provided information on the data quality and reliability. Phase II RI data were validated in accordance with NJDEP guidance on data usability.

As a result of these evaluations, data are considered to be of known and acceptable quality and are considered valid and usable for decision-making purposes (Hercules 2007). Available site characterization data used in the ERA are described below.

Each media-specific volume of the Phase II RIR included a data quality section that evaluated data presented in the report based on NJDEP's Data of Known Quality Protocols Technical Guidance (DKQP Guidance; NJDEP 2014). These data were found to be of acceptable quality for use in remedial decision making, including the ERA.

Data reviews consistent with DKQP Guidance were conducted for data generated during the post-RI ERA activities. Certain data and analyses are not addressed in the DKQP Guidance, and in these cases a general data quality review was performed. Post-RI ERA data were found to be of acceptable quality for use in remedial decision making, including the ERA.

4.1.1 Ecological Risk Assessment Dataset Selection

Data selected for the ERA include surface soil and sediment samples from the 0- to 12-inch interval below soil/sediment surface (bss); representative of the BAZ) and surface water sample results. Where historical information contained in the database was ambiguous (e.g., sample interval recorded as 12 inches without listing both a start and ending depth bss), samples where over 50 percent of their depth interval within the 0 to 12 inch bss interval were included in the ERA dataset. The dataset was specifically filtered to include samples with a start depth of 0-6 inch bss and an end depth of 0-18 in bss. This definition accounts for the size and variability of the SI/RI dataset and includes sample intervals spanning the BAZ. **Table 4-1** summarizes samples available for the ERA dataset.

Consistent with the approach outlined in Section 3.2.3, the dataset was separated to focus on data from sample locations within the Remedial Area and excludes data from the Areas of Presumed Remedial Action (hereafter referred to as the ERA dataset [**Appendix E**]).

As previously discussed, the ERA dataset presented in the 2016 EE/ERA has been updated to incorporate sampling and analyses as detailed in the following documents:

Reference Location	Document
Attachment 9	Updated SSRP (KJ 2019)
Appendix D	TLWP Implementation
Appendix C	Aquatic ERASSM Implementation

The ERA dataset was also separated by medium: soil (1600+ samples from 1300+ locations), sediment (800+ samples from 400+ locations), and surface water (400+ samples from 300+ locations). **Table 4-1** presents the ERA dataset separated by constituent class. **Figures 4-1 through 4-14** illustrate the spatial coverage of sample locations by constituent class.

The terrestrial exposure area is shown in **Figure 3-2**. As discussed in Section 3.3.3, the soil dataset was evaluated as a whole based on the similarity in constituent composition and habitat suitability across former manufacturing areas of the Facility. Soil sample locations are presented on **Figures 4-1 A-E**.

Sediment and surface water datasets were compiled by subdrainage exposure areas. The five subdrainage exposure areas within the NDA and SDA are presented in **Figure 3-1**. NDA sample locations are presented in **Figures 4-2 through 4-6**. SDA sample locations are presented in **Figures 4-7 through 4-14**.

The figures illustrate the spatial coverage of samples across the exposure areas. The Phase II RIR (Hercules 2016c) presents sample locations, sample IDs, and results on a sample-by-sample basis. RI conclusions indicate that constituents occur primarily within the former operational areas and acknowledge that the horizontal and vertical extent of constituents is well defined.

4.1.2 Data Management

Specific data handling was required to achieve spatial representativeness for the ERA. Duplicate analyses at one sample location (e.g., field duplicates), or constituents analyzed by more than one method, create spatial disparity among the dataset during statistical evaluation. Additional data reduction and handling was conducted to minimize these influences. The following subsections present methods and rationale for additional database management to facilitate the COPEC screen.

4.1.2.1 PCDDs and PCDFs

The PCDD/F soil sample dataset is relatively small (n=20) compared to the Facility-wide soil characterization dataset. The spatial coverage of the datasets differ considerably, as sampling for polychlorinated dibenzo-*p*-dioxins (PCDDs) and polychlorinated dibenzo-*p*-furans (PCDFs) focused on four former burning grounds at the Facility at the request of NJDEP. Given these differences, PCDD/F is evaluated separately. Results of the evaluation are discussed in sections

of this ERA where applicable. PCDD/F was detected in two of the four former burning grounds and both of these areas were identified as APRAs in the 2016 EE/ERA. The soil volume of the Phase II RIR (Hercules 2016c) provides additional information regarding the basis for PCDD/F soil sampling at the Facility. The PCDD/F evaluation included in the 2016 EE/ERA (**Attachment 1**) remains current, as no additional PCDD/F work has been conducted at the Facility within the area being evaluated in this ERA.

4.1.2.2 Duplicate Samples

Field duplicate samples are presented in the dataset (**Appendix E**) next to their parent sample. One numerical representation of parent/duplicate data was derived for use in risk calculations to avoid spatial weighting bias associated with two results at the same sample location. When the parent/duplicate data were either both detects or both non-detects, sample results were averaged. Because field duplicates are co-located, sample variation caused by potential heterogeneity is also included in the measurement (USEPA 1991). The average concentration provides for the best representation of concentration at that location. In situations where one-half of a parent/duplicate pair was a detect and the other half was non detect, the detected concentration was used, which provides for a conservative measurement.

4.1.2.3 Redundant Analytes – SW846 Methods 8270 and 8330

Eight constituents occur on the analyte lists for both the SW846 8270 semivolatile organic compound (SVOC) and SW846 8330 E&E methods. As such, the SI/RI database contains two results for each constituent at each sample location where both methods were used.

For this ERA, NJDEP's acceptance of data based on laboratory certification (which is based on the analytical methods meeting precision and accuracy targets) was used. Method SW846 8270 is a gas chromatography/mass spectrometry (GC/MS) method and SW846 8330 uses high-performance liquid chromatography (HPLC); each method offers distinct advantages and disadvantages depending on the target analyte. The table below summarizes the eight analytes and associated NJDEP-approved analytical methods, and notes the data selected for use in this ERA.

Analyte	NJDEP Laboratory Certification[1]		Data used in ERA
	SW846 8270	SW846 8330	
2,4-DNT	X	X	SW846 8270
2,6-DNT	X	X	SW846 8270
2-nitrotoluene		X	SW846 8330
3-nitrotoluene		X	SW846 8330
4-nitrotoluene		X	SW846 8330
Nitrobenzene	X	X	SW846 8330
1,3,5-trinitrobenzene	X	X	SW846 8330
2,4-dinitrophenol	X		SW846 8270

Note:
[1]Application for Certification of Environmental Measurements, Part III – Analytical Testing Parameters (NJDEP 2014).

For analytes with one NJDEP-approved laboratory analytical method, data from the approved method was selected for use in the ERA. Where the NJDEP approves both analytical methods, additional information related to precision and accuracy of the methods as they relate to analytes (or analyte families) was evaluated. For nitrotoluene compounds, the GC/MS method (8270) generates chromatographs enabling the analytical laboratory to more precisely identify individual compound peaks and accurately quantify associated concentrations. Conversely, the HPLC

(8330) methods provide superior performance for the analysis of nitrobenzene compounds. This rationale is consistent with that provided in the Phase I RIR (Hercules 2007).

4.1.2.4 Redundant Analytes – SW846 Methods 8260 and 8270

Six constituents occur on the analyte lists for both the SW846 8270 SVOC and SW846 8260 volatile organic compound (VOC) methods. As such, the database contains two results for each constituent at each sample location where both methods were used.

The NJDEP approves both analytical methods for six constituents (1,2,4-trichlorobenzene, 1,2-dichlorobenzene, 1,3-dichlorobenzene, 1,4-dichlorobenzene, hexachloro-1,3-butadiene, and naphthalene). None of these constituents were retained as COPECs during the initial data screen (see Section 4.2.2).

4.2 Identification of Constituents of Potential Ecological Concern

COPECs are identified via a comparison of generic ESBs to maximum detected constituent concentrations in environmental media. Generic ESBs represent a threshold concentration that a majority of target organisms (e.g., plants, invertebrates) can tolerate and a concentration that may cause adverse effects in specific organism communities. Generally, ESBs were developed from various datasets that relate constituent concentrations in an environmental medium with occurrence of effects in sensitive species. Generic ESBs do not consider site-specific factors that may affect constituent bioavailability and toxicity (e.g., pH, organic carbon content). Ecological screening benchmarks utilized in this ERA are summarized below.

4.2.1 Ecological Screening Benchmarks

Ecological screening benchmarks were selected from NJDEP's Ecological Screening Criteria (ESC) table (NJDEP 2009) and supplemented with preferentially selected ESBs based on a review of the following additional sources:

- Resource Conservation and Recovery Act (RCRA) Region 5 Ecological Screening Levels (ESLs; USEPA 2003a)
- Ecological Soil Screening Levels (EcoSSLs) (USEPA 2007a)
- Ecotoxicology of Explosives (Sunahara et al. 2009)
- Nitroaromatic Munition Compounds: Environmental Effects and Screening Values (Talmage et al. 1999)
- Region 3 Biological Technical Assistance Group - Freshwater Sediment and Freshwater Screening Benchmarks (USEPA 2006)
- Munition constituents: Preliminary sediment screening criteria for the protection of marine benthic invertebrates (Pascoe et al. 2010)
- Ecotoxicological Serious Risk Concentrations for soil, sediment, and (ground)water (Verbruggen et al. 2001)
- USEPA's Ecotox Database (available at http://cfpub.epa.gov/ecotox/)

- Acute Oral Toxicity and Repellency of 933 Chemicals to House and Deer Mice (Schafer et al. 1985)
- Comparison of Lethality, Reproduction, and Behavior as Toxicological Endpoints in the Nematode *Caenorhabditis elegans* (Dhawan et al. 1999)
- Toxicity of Trihalomethanes to Common Carp Embryos (Mattice et al. 1981).

Table 4-2 summarizes ESBs used in this ERA. For constituents lacking ESB, surrogate values from constituents with similar properties (e.g., chemical class, molecular structure) were selected. Surrogate values and their sources are footnoted in **Table 4-2.**

Surface water ESBs for certain metals (i.e., cadmium, chromium, copper, nickel, silver, and zinc) presented in the NJDEP ESC table are hardness-dependent. Representative hardness values were calculated for both the NDA and SDA using available surface water data. An average hardness value and 95 percent upper confidence limit (95UCL) were calculated for each area. The table below summarizes hardness values, presented as milligrams per liter (mg/L) calcium carbonate.

Representative Hardness Values (mg/L)		
	NDA	SDA
Average	57	120
95UCL	84	155

In both the NDA and SDA, the average hardness value was lower than the 95UCL value. As such, the calculated screening values were lower using the average hardness, which represents the more conservative approach for screening surface water data. Screening values were calculated for both total and dissolved metals per the NJDEP ESC table (2009) equations using a conversion factor. **Table 4-2** presents hardness-dependent ESB.

4.2.2 COPEC Screen

The maximum concentration of each detected constituent was compared to its ESB or ESBTU to calculate a hazard quotient (HQ). Constituents with HQs greater than 1 or those lacking an ESB were retained as COPECs. Constituents were not retained as COPECs if they were not detected (i.e., 0 detections), had a low frequency of detection (i.e., less than 5 detections irrespective of the number of samples analyzed), or if the HQ was less than 1.

Metals commonly considered essential nutrients (i.e., calcium, iron, magnesium, potassium, and sodium) were not retained as COPECs. The soluble fraction of aluminum in soil and sediment can pose a potential risk to ecological receptors; however, it is understood that solubility, and therefore bioavailability, is based on the measured pH of onsite soil/sediment. Potential ecological risks associated with aluminum are only expected to occur when soil/sediment pH is less than 5.5 (USEPA 2003b). The average for soil pH was calculated from both field (pH = 6.0) and laboratory samples (pH = 6.3). The average was also calculated for NDA and SDA sediment pH from both field (NDA pH = 6.1 and SDA pH = 7.1) and laboratory samples (NDA pH = 5.7 and SDA pH = 7.1). As such, aluminum was not retained as a COPEC in soil or sediment.

Tables 5-1 through 5-5 present the COPEC screen and associated summary statistics by sample media and exposure area.

The following sections summarize selected COPECs by media, exposure area, and constituent class. **Table 4-3** summarizes COPECs identified onsite.

4.2.2.1 Terrestrial Exposure Area

4.2.2.2 Facility-Wide Soil

A total of 39 COPECs were identified in Facility-wide soil (**Table 4-4)** based on a comparison of the maximum detected concentration to ESBs. The following table summarizes COPECs by constituent class. **Table 4-9** tracks the COPEC progression through the various evaluation methods.

Facility-Wide Soil COPEC Screen Summary				
VOCs	**SVOCs**	**Metals**	**Explosives**	**PCBs**
Benzene	2,4-DNT	Antimony	2,4,6-TNT	Aroclor-1254
Bromomethane	2,6-DNT	Arsenic	2-Amino-4,6-DNT	Aroclor-1260
--	Benzo(g,h,i)fluoranthene	Cadmium	4-Amino-2,6-DNT	Total PCBs
--	Benzo[a]anthracene	Chromium	Nitrocellulose	--
--	Benzo[a]pyrene	Cobalt	Nitroglycerin	--
--	Bis(2-Ethylhexyl)phthalate	Copper	HMX	--
--	Butylbenzylphthalate	Lead	--	--
--	Chrysene	Manganese	--	--
--	Di-n-butylphthalate	Mercury	--	--
--	Naphthalene	Nickel	--	--
--	N-Nitroso-Di-N-Propylamine	Selenium	--	--
--	N-Nitrosodiphenylamine	Silver	--	--
--	Phenanthrene	Thallium	--	--
--	--	Vanadium	--	--
--	--	Zinc	--	--

Notes: DNT = dinitrotoluene; HMX = octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine; PCB = polychlorinated biphenyl; TNT = trinitrotoluene

4.2.2.3 Aquatic Exposure Areas

Aquatic exposure area COPECs were identified by subdrainage areas within the NDA and SDA (further discussed in **Section 3.2.3.2**). **Tables 4-10 and 4-11** track the COPEC progression through the various evaluation methods.

4.2.2.4 Northern Drainage Area

The five subdrainage areas within the NDA encompass a series of aquatic features including ponds, tributaries, and vernal pools. **Figure 3-1** illustrates the five NDA subdrainage areas.

4.2.2.4.1 Surface Water COPEC Summary

Six COPECs were identified in NDA subdrainage area surface water (**Table 4-5** and below) based on a comparison of the maximum detected concentration to ESBs.

NDA Subdrainage Areas - Surface Water COPEC Screen Summary					
COPEC	**Duck Pond**	**Eastern Tributary**	**Northeast Ponds**	**Unnamed Ponds**	**Western Tributary**
Aluminum	-	-	-	+	+
Cadmium	-	-	+	-	-
Copper	-	-	-	-	+
Lead	-	+	-	-	+
Manganese	-	-	-	+	+
Selenium	-	-	-	-	+
Zinc	-	-	-	+	+

+ = screened in as COPEC; - = screened out as COPEC

Metals were retained as COPECs based on a comparison of dissolved metals data to ESBs, which more accurately approximates the fraction of the metal that is available for uptake by aquatic organisms (i.e., bioavailable, not bound to suspended particulates) (International Council on Mining and Metals [ICMM] 2007; Meyer et al. 2007; USEPA 1993a) relative to total metals data. **Table 4-5** presents both the total and dissolved metals data for any metal that exceeds ESB. COPEC retention summarized in the table above is based on dissolved metals results.

Table 4-5 presents the results of the COPEC screen and provides summary statistics for COPECs identified in surface water in the NDA subdrainage areas.

4.2.2.4.2 Sediment COPEC Summary

Eighteen COPECs were identified in NDA subdrainage area sediment (**Table 4-6** and the following summary table) based on a comparison of the maximum detected concentration to ESBs.

NDA Subdrainage Areas - Sediment COPEC Screen Summary					
COPEC	**Duck Pond**	**Eastern Tributary**	**Northeast Ponds**	**Unnamed Ponds**	**Western Tributary**
Explosives					
Nitroglycerin	+	-	-	-	-
Metals					
Arsenic	+	+	+	+	+
Cadmium	+	-	-	+	+
Chromium	+	-	-	+	+
Copper	+	+	+	+	+
Lead	+	+	+	+	+
Mercury	-	-	+	+	+
Nickel	+	+	+	+	-
Silver	-	-	+	-	-
Zinc	+	+	+	+	+
PAHs					
Benzo(a)anthracene	+	-	-	+	-
Benzo(a)pyrene	+	-	-	+	-
Benzo(g,h,i)perylene	+	-	-	+	-
Benzo(k)fluoranthene	+	-	-	+	-
Chrysene	+	-	-	+	-
Fluoranthene	+	-	-	+	-
Phenanthrene	+	-	-	-	-
Pyrene	+	-	-	-	-

Notes: + = screened in as COPEC; - = screened out as COPEC

Table 4-6 presents the results of the COPEC screen and provides summary statistics for COPECs identified in sediment in the NDA subdrainage areas (**Figure 3-1**).

4.2.2.5 Southern Drainage Area

The SDA encompasses aquatic areas south and west of the surface water divide described in Section 3.2.3.2. Aquatic features include intermittent and perennial ditches draining to, and including, the southern wetland complex. **Figure 3-1** shows the SDA.

4.2.2.5.1 Surface Water COPEC Summary

Two COPECs were identified in SDA subdrainage area surface water (**Table 4-7** and the following summary table) based on a comparison of the maximum detected concentration to ESBs.

SDA Subdrainage Areas - Surface Water COPEC Screen Summary								
COPEC	Central Drainage Basin	Development Stream	Maint-Dyn West	Maint-Dyn East	Maint NG	Offsite Streams Lower	Offsite Streams Upper	TNT-PETN-NG Ditches
Lead	-	-	+	-	-	-	-	-
Manganese	-	-	-	-	-	-	-	+

+ = screened in as COPEC; - = screened out as COPEC

Metals were retained as COPECs based on a comparison of dissolved metals data to ESBs, which more accurately approximates the fraction of the metal that is available for uptake by aquatic organisms (i.e., bioavailable, not bound to suspended particulates) (International Council on Mining and Metals [ICMM] 2007; Meyer et al. 2007; USEPA 1993a) relative to total metals data. **Table 4-7** presents both the total and dissolved metals data for any metal that exceeds ESB. COPEC retention summarized in the table above is based on dissolved metals results.

Table 4-7 presents the results of the COPEC screen and provides summary statistics for COPECs identified in surface water in the NDA subdrainage areas.

4.2.2.5.2 Sediment COPEC Summary

Twenty-three COPECs were identified in SDA subdrainage area sediment (as detailed in **Table 4-8** and summarized in the table below) based on a comparison of the maximum detected concentration to ESBs.

SDA Subdrainage Areas - Sediment COPEC Screen Summary								
COPEC	**Central Drainage Basin**	**Development Area Stream**	**Maintenance - Dynamite Area - East**	**Maintenance – Dynamite Area - West**	**Maintenance – NG Area**	**Misc. Offsite Streams - Lower**	**Misc. Offsite Streams - Upper**	**TNT-PETN-NG Ditches**
Metals								
Arsenic	+	+	+	+	+	+	+	+
Cadmium	+	+	+	+	+	+	+	+
Chromium	+	+	+	+	+	+	+	+
Copper	+	+	+	+	+	+	+	+
Lead	+	+	+	+	+	+	+	+
Mercury	+	+	+	+	+	+	+	+
Nickel	+	-	+	+	+	-	+	+
Silver	-	-	+	+	+	-	-	-
Zinc	+	+	+	+	+	+	+	+
PAHs								
Acenaphthene	-	-	-	+	-	-	-	-
Acenaphthylene	-	-	+	+	-	+	-	-
Anthracene	-	-	+	+	-	+	-	-
Benzo(a)anthracene	-	-	+	+	+	+	-	+
Benzo(a)pyrene	-	-	+	+	+	+	-	+
Benzo(g,h,i)perylene	-	-	+	+	+	+	-	+
Benzo(k)fluoranthene	-	-	+	+	+	+	-	-
Chrysene	-	-	+	+	+	+	-	+
Dibenzo(a,h)anthracene	-	-	+	+	-	+	-	+
Fluoranthene	+	-	+	+	+	+	-	+

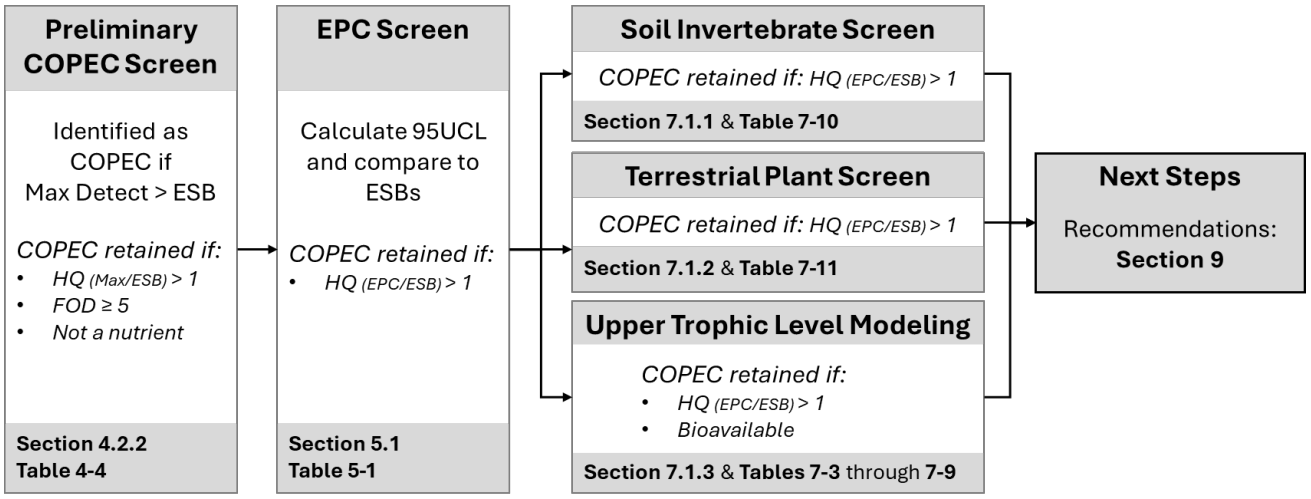
Phenanthrene	-	-	+	+	+	+	-	+
Pyrene	+	-	+	+	+	+	-	+

Notes: + = screened in as COPEC; - = screened out as COPEC

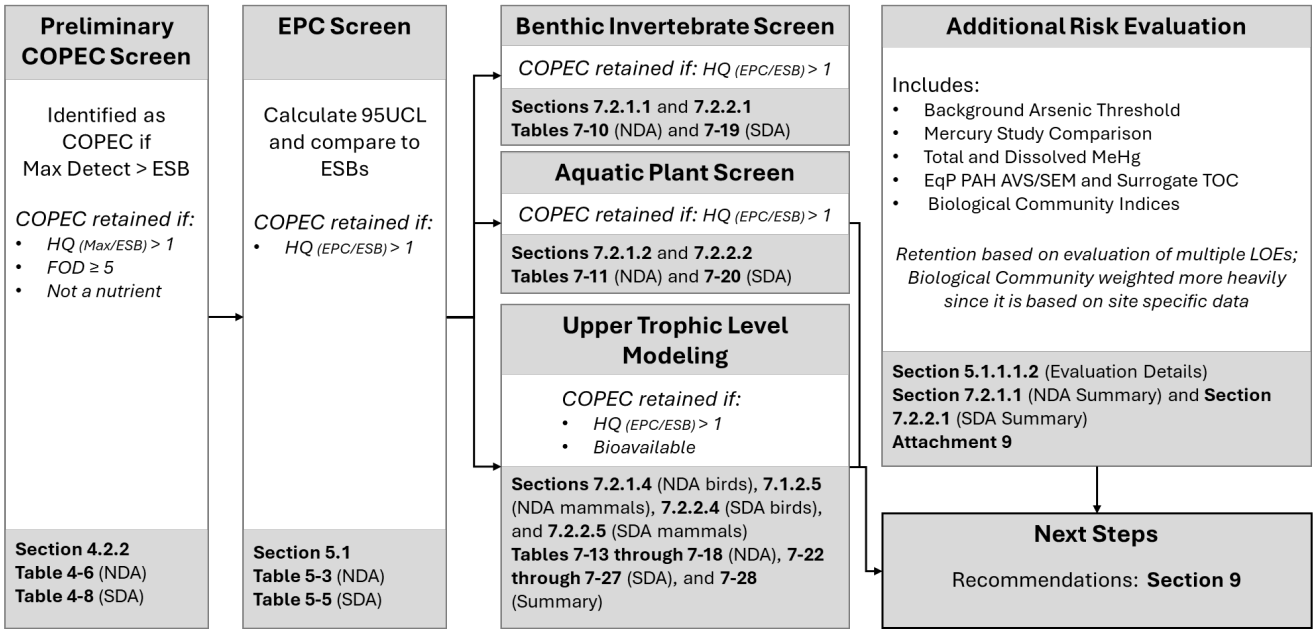
4.3 Process Summary

In Section 4, initial COPECs have been identified. Sections 5 and 6 evaluate exposures and effects, respectively. Assessment results presented in Section 5 and 6 are brought together in the risk characterization presented in Section 7. Summary tables referenced in Section 7 present the results of these stepwise processes. The COPEC identification, screening, and evaluation processes for each media type are illustrated in the graphics that follow.

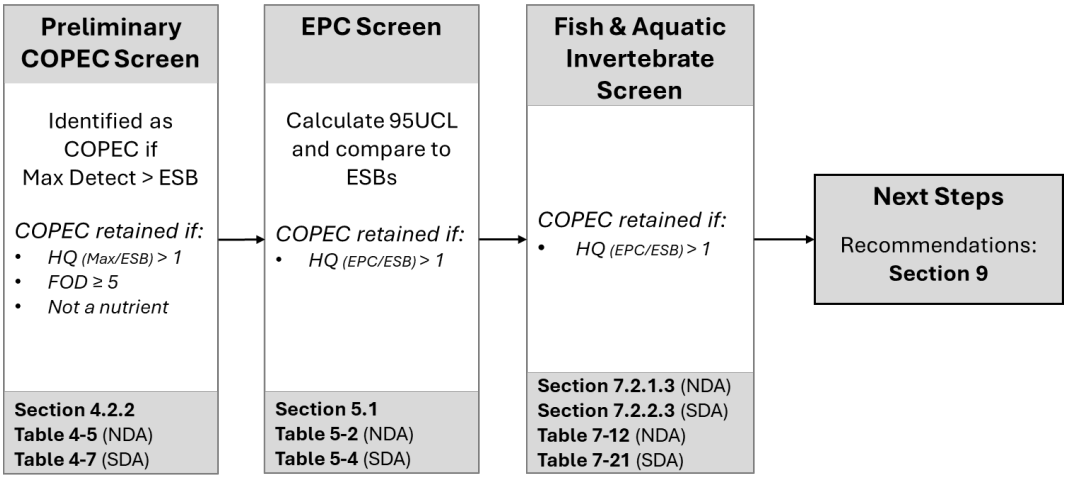
SOIL EVALUATION PROCESS:



SEDIMENT EVALUATION PROCESS:



SURFACE WATER EVALUATION PROCESS:



Notes:
ESB = ecological screening benchmark (Section 4.2.1)
EPC = exposure point concentration (Section 5.1)
FOD = frequency of detection
HQ = hazard quotient
95UCL = 95% upper confidence limit

Tables 4-9 through 4-11 additionally present a summary of the data for each stage of the evaluation process for each media type. These tables are intended as a companion reference to the text to help visualize how each stage of the evaluation fits into the overall process, and how individual COPECs are either retained or screen out.

Section 5: Ecological Exposure Assessment

The exposure assessment estimates a dose for each COPEC to which a receptor could be exposed. Exposure to plants and soil invertebrates (i.e., earthworms) is estimated solely by the Facility-specific soil concentration. Exposure to fish is estimated by the Facility-specific surface water concentration. Exposure to benthic invertebrates is estimated by the Facility-specific sediment concentration. Exposure to upper-trophic-level wildlife (birds and mammals) is estimated using an average daily dietary dose calculated via a food web model that incorporates estimated concentrations of COPEC in the diet (Section 5.2).

Section 5.1 presents the process by which exposure point concentrations were derived (Section 5.1.1) and summarizes multiple lines of evidence generated during the ERA process since the 2016 EE/ERA beyond the comparison of COPEC concentrations to ESBs. These lines of evidence are media-, constituent-, and/or exposure area-specific based on the results of prior work and the specific measurement endpoint they evaluate. For example, Section 5.1.1.1.1 presents the results of an evaluation of the bioavailability of lead in soil using a sequential extraction process. These activities resulted from lead in soil emerging as the primary risk driver in the 2016 EE/ERA, identification of areas of higher lead concentrations in soil presented in the desktop evaluation section of the ERAWP, and the evaluation of form, concentration, and bioavailability completed per the TLWP. These lines of evidence are compiled at the end of Section 5 and exposure area- and COPEC-specific risk management decisions are presented using a weight of evidence approach.

5.1 Exposure Point Concentrations

The exposure point concentration (EPC) is a conservative estimate of the chemical concentration in an environmental medium to which a receptor may be exposed. An individual receptor is assumed to be equally exposed to media within all portions of the exposure unit over the time frame of the risk assessment (USEPA 2002).

USEPA recommends using the average concentration to represent "a reasonable estimate of the concentration likely to be contacted over time" (USEPA 1989). In addition, USEPA (1992b) notes that “because of the uncertainty associated with estimating the true average concentration at a site, the 95 percent upper confidence limit (95UCL) of the arithmetic mean should be used for this variable.” EPCs (95UCLs) were calculated for COPECs identified at the Facility in soil, sediment and surface water, as indicated in **Tables 5-1 through 5-5**.

Although PCB Aroclors 1254 and 1260 were selected as COPECs during the initial data screen, Total PCBs (sum of detected Aroclors) was carried forward for use in food web modeling. This value provides a more conservative estimate of the concentration of PCBs in Facility media. Aroclors are mixtures of individual PCB congeners, and Total PCBs incorporates the congeners that make up Aroclors 1254 and 1260.

5.1.1 Site Media

Soil, surface water, and sediment 95UCLs were calculated using ProUCL Version 5.2.00. Per USEPA (2022) guidance, 95UCL calculation requires a dataset with at least eight samples and

five detects. For datasets that do not meet this requirement, the maximum concentration was used as the EPC.

Tables 5-1 through 5-5 present EPCs and their bases for terrestrial and aquatic exposure areas. **Appendix F** presents ProUCL output files.

5.1.1.1 Bioavailability and Chemical Speciation

Per regulatory guidance (USEPA 1997, NJDEP 2023), the 2016 EE/ERA assumed COPECs were 100% bioavailable to ecological receptors. In reality, the bioavailability of constituents depends on the form originally released, as well as various physical and chemical characteristics of the medium.

As discussed in Section 2.3.2, field sampling plans were developed for terrestrial and aquatic exposure areas, respectively, to evaluate:

- bioavailability, speciation, and physical forms of lead in soil
- bioavailability and speciation of metals and polycyclic aromatic hydrocarbons (PAHs) in subdrainage areas

The following sections detail lines of evidence related to Facility-specific bioavailability and/or speciation of COPECs in associated environmental media.

5.1.1.1.1 Terrestrial Exposure Area

5.1.1.1.1.1 Lead Bioavailability

Results of the 2016 EE/ERA and ERAWP desktop evaluation guided development of the TLWP (**Attachment 8**), which outlined data collection activities to refine existing conclusions regarding lead in soil and its potential risk to terrestrial receptors.

Appendix D details implementation of the TLWP field sampling plan in December 2018. Terrestrial areas of enrichment (AoEs), selected based on lead concentrations in soil, historical release mechanism(s), and anticipated form, evaluated in the TLWP now occur within updated APRAs (as discussed in Section 3.4.1). Sequential extraction procedure (SEP) analysis data generated during TLWP implementation are used in the ERA to evaluate the bioavailability of lead to terrestrial receptors.

Interpretation of the SEP results relies on the following information about each step and the associated complexation/binding of lead.

Step 1 - Exchangeable Phase: This extraction includes trace elements that are reversibly sorbed to soil minerals, amorphous solids, and/or organic material by electrostatic forces.

Step 2 - Carbonate Phase: This extraction targets trace elements that are sorbed or otherwise bound to carbonate minerals.

Step 3 - Non-Crystalline Materials Phase: This extraction targets trace elements that are complexed by amorphous minerals (e.g. iron).

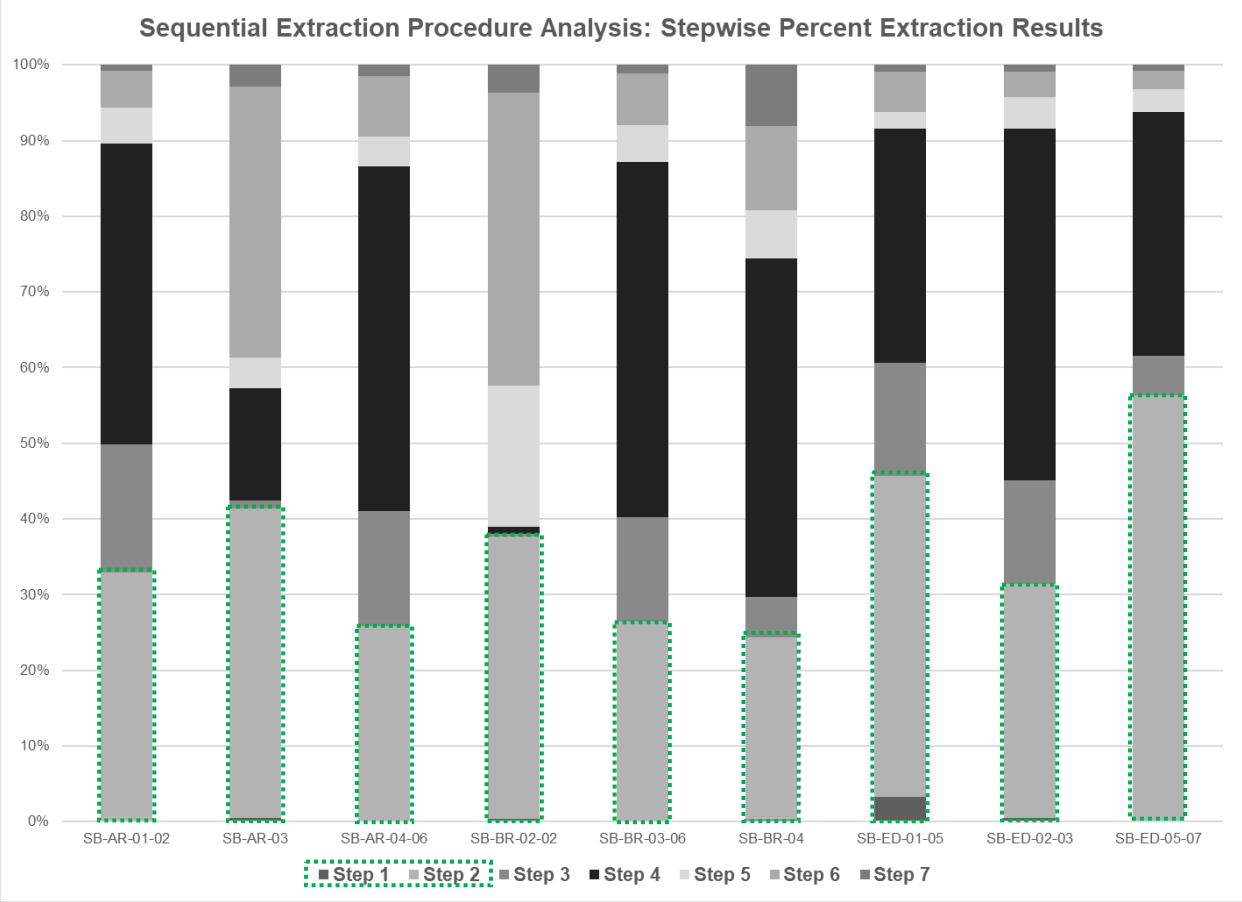
Step 4 - Metal Hydroxide Phase: Trace elements bound to hydroxides of iron, manganese, and/or aluminum.

Step 5 - Organic Phase: This extraction targets trace elements strongly bound via chemisorption to organic material.

Step 6 - Acid/Sulfide Fraction: The extraction is used to identify trace elements precipitated as sulfide minerals.

Step 7 - Residual Fraction: Trace elements remaining in the soil after the previous extractions will be distributed between silicates, phosphates, and refractory oxides.

The chart below presents SEP analysis results broken down by stepwise percent extraction.



The fraction of total lead extracted in Steps 1 and 2 of SEP analysis represent the exchangeable and carbonate phases, respectively. The exchangeable phase is associated with the potentially bioavailable fraction where variations in soil chemistry can influence sorption and desorption. The carbonate phase represents a fraction where lead is associated with carbonates, whereby bioavailability and mobility are a function of pH. These two phases collectively comprise the weakly bound fraction of lead (Tessier et al. 1979) and are most readily bioavailable to ecological receptors.

Results of SEP analysis indicate that 24 to 56 percent of total lead concentrations in soil are weakly bound and potentially bioavailable. As such, terrestrial receptor risk characterization (Section 7.1) incorporates 24, 56, and 100% bioavailable lead fractions in soil direct contact EPCs and terrestrial food web modeling.

5.1.1.1.1.2 Spatial Analysis of Lead and Copper

Spatial weighting using Thiessen polygons is a commonly used approach (NJDEP 2025, USEPA 2019, ITRC 2016) to visualize and weigh analytical data by representing the spatial area each sample influences - often referred to as surface-weighted average concentrations (SWACs). For upper-trophic-level receptors, spatial analysis of soil COPEC concentrations in terrestrial habitat patches can support the evaluation of probabilistic risk distributions, accounting for spatial exposure variability in the Facility-wide terrestrial exposure area. The first step of this approach is presented in **Figures 5-1** through **5-4**.

Thiessen polygons were calculated for lead (**Figure 5-1**) and copper (**Figure 5-3**) within the terrestrial exposure area. The spatially-weighted data were then compared to back-calculated, risk-based, site-specific ESCs (SSESC) for lead (488 mg/kg) and copper (312 mg/kg) that were developed using the American robin model and the following equation:

$$EPC = \frac{HQ \times TRV \times BW}{AUF \times \left(IRsed + \left[IRfood \times \left[\left(BAF_{invert} \times \%diet\right) + \left(BAF_{plant} \times \%\,diet\right)\right]\right]\right)}$$

EPC = exposure point concentration
TRV = toxicity reference value
BW = body weight (kg)
AUF = area use factor
IRsed = Sediment Ingestion Rate (kg/day)
IRfood = Daily Ingestion Rate (kg/day)
BAF = Bioaccumulation Factor
%diet = Dietary Composition

These calculations are presented in **Appendix G**.

High level findings included:

- The spatially-weighted average for lead was 266 mg/kg, which is below the SSESC of 488 mg/kg. Additionally, 94 percent of the terrestrial exposure area had a lead concentration less than the SSESC
- The spatially-weighted average for copper was 68.8 mg/kg, which is below the SSESC of 312 mg/kg. Additionally, 98 percent of the terrestrial exposure area had a copper concentration less than the SSESC

These results will steer future risk assessment activities to those areas where SWACs exceed SSESCs. Section 9 presents the initial steps and a framework to guide supplemental risk characterization activities associated with lead and copper in the terrestrial exposure area.

5.1.1.1.2 Aquatic Exposure Areas

Results of the 2016 EE/ERA and ERAWP desktop evaluation guided development and implementation of data collection activities to evaluate bioavailability and speciation of metals and PAHs in aquatic subdrainage exposure areas. Implementation of the ERAWP field sampling plan occurred in June 2016 and May 2018, and implementation of the Aquatic ERASSM field sampling plan occurred in July 2019. Analytical results from aquatic field sampling implementation are incorporated in the ERA dataset as indicated in Section 4.1.1.

The following sections detail results of aquatic sampling activities as they pertain to constituent bioavailability and chemical speciation of COPECs in aquatic exposure media (i.e., sediment and surface water) and COPEC exposure to benthic invertebrate communities.

5.1.1.1.2.1 Metals

5.1.1.1.2.1.1 Arsenic

As detailed in the ERAWP (**Attachment 1**) and Updated SSRP (**Attachment 9**), sediment arsenic concentrations in aquatic exposure areas were evaluated against background threshold of arsenic at the Facility (90th percentile concentration of 11.6 mg/kg). Background arsenic concentrations at the Facility are less than NJDEP's SRS value of 19 mg/kg based on state-wide background concentrations, and greater than the regional background threshold value (7.32 mg/kg; NJDEP 2003). The presence of arsenic at the Facility is likely attributable to historic fill (as detailed further below).

The following table summarizes a series of datasets representative of areas onsite and results of sediment arsenic analyses in NDA and SDA subdrainage areas where potential risk remained uncertain following the 2016 EE/ERA.

Arsenic Background Threshold and Sediment Summary Statistics					
Dataset	**Detection Frequency**	**Min.**	**Max.**	**Arithmetic Mean**	**90th Percentile Concentration**
		mg/kg			
Background Datasets					
Statewide Background – NJDEP SRS	NA	NA	NA	NA	19
Regional Background - NJDEP (2003)	13/13	NA	NA	NA	7.32
Facility Background - Undeveloped Area Soil	127/131	1.6	164	7.53	14.5
Less outlier	126/130	1.6	21.1	6.28	11.6
Remedial Area Soil Datasets					
Soil – No Historic Fill	538/543	1.4	675	11.8	15.5

Soil – Historic Fill	575/579	0.71	1,150	27.6	36.0
Aquatic Exposure Area Sediment Datasets					
Duck Pond	35/45	1.27	41.1	8.55	9.68[a]
Unnamed Ponds	21/23	1.86	111	13.2	**34.5**[a]
Central Drainage Basin	13/15	2.64	97.3	35.8	**51.4**[a]

Misc. Offsite Streams – Upper	26/31	0.69	31.8	4.29	6.14[a]
TNT-PETN-NG Ditches	23/25	1.67	192	24.6	**49.9**[a]

Notes: Bolded values indicate exceedance of Facility-specific background threshold (11.6 mg/kg). Summary statistics incorporate historical and supplemental analyses.
Min. – minimum
Max. – maximum
mg/kg – milligrams per kilogram
[a]95UCL calculation

Throughout numerous periods of expansion and development, historic fill from multiple local sources was used onsite to increase grade, eliminate shallow ponds/wet areas, improve drainage, increase compatibility of the soils to allow construction of large manufacturing complexes, and establish both narrow gauge and standard gauge rail beds throughout the Facility. Coal combustion byproducts from the local iron foundries made up the majority of historic fill material brought onsite. Historical record confirms that blast furnaces at local foundries burned primarily Anthracite coal (Bayley 1910).

The use of coal combustion byproducts as historic fill, and presence of arsenic in historic fill material is well documented (NJDEP 2013). USGS (2006) found relatively high arsenic levels in northern Appalachian coal and its combustion byproducts. USEPA (1998b) found Anthracite coal to contain arsenic at an average concentration of 8 mg/kg prior to combustion. NJDEP's historic fill database includes records of arsenic in historic fill samples at over 1,000 milligrams per kilogram.

Arsenic occurs at a range of concentrations within the former manufacturing areas of the Facility with no discernable pattern linking former operations to arsenic concentrations. As illustrated above, arsenic concentrations are higher in areas of historic fill placement, and consistent with local and regional background beyond the footprint of historic fill.

Surface-water drainage pathways onsite cut through areas of historic fill, flow in streambeds confined by historic fill, and discharge through culverts anchored/embedded in historic fill material. These interactions with upland/soil sources, and the influences of erosion, bedload sediment transport, and deposition, appear to be responsible for the presence and distribution of arsenic in Facility sediment. Arsenic in Facility sediments appears attributable to historic fill surrounding and within aquatic features.

Doughten et al. (2015) identified pentavalent arsenic (As(V)) as the dominant form in coal combustion byproducts. As(V) is less bioavailable and less toxic than trivalent arsenic (As(III)), and does not readily leach from coal combustion byproducts (USGS 2006, Doughten et al. 2015; Shah et al 2007). Additionally, reduction of As(V) to the more soluble and toxic As(III) occurs slowly, even in reducing environments, and is readily inhibited by the binding of As(V) while As(III) is rapidly oxidized to As(V) (Brannon 1987, Battelle & Exponent 2000). Arsenic is readily bound by a number of metals, including sulfides and manganese (Nriagu 1994, Battelle & Exponent 2000*).* Manganese is regionally elevated in soils and sediments (NJDEP 2003) and is present in sediment onsite. Sulfides are also present across aquatic features onsite and likely serve as a binding complex for divalent metals as well as arsenic.

Arsenic is not present above ESBs in surface water in aquatic features onsite, further supporting its presence in sediment in a relatively immobile and insoluble form.

Benthic invertebrate community surveys were performed (as detailed further in Section 5.1.1.2) in subdrainage areas where sediment arsenic exceeded the Facility-specific background threshold concentration (i.e., Unnamed Ponds, Central Drainage Basin, Maintenance NG Area, and TNT-PETN-NG Ditches). The resulting biological data (presented in Section 5.1.1.2) provides an additional LOE to be evaluated in a weight of evidence approach with the source attribution, form, and solubility/mobility discussions presented herein.

5.1.1.1.2.1.2 Mercury

In subdrainage areas where potential risk remained uncertain following ERAWP implementation, a mercury study comparison and mercury speciation analysis were performed. Results of these analyses are discussed in the following sections.

5.1.1.1.2.1.2.1 Mercury Study Comparison

The mercury study comparison relied upon Conder et al.'s (2015) review of laboratory and field studies characterizing mercury-specific-effect thresholds. Conder et al.'s study compiled 30 studies (7 spiked-sediment bioassays, 23 field-collected sediment bioassays from mercury-contaminated sites) that provided mercury sediment quality values (SQVs) for protection of benthic invertebrates. Mercury concentrations within each subdrainage area were compared to the compiled no observed effect concentrations (NOECs). Where maximum detected mercury concentrations in sediment are less than or within the range of spiked-sediment NOECs from Conder et al. (2015; 0.59 – 11 mg/kg), risk to benthic invertebrate communities is considered unlikely. Results of this evaluation are detailed further in the Updated SSRP (**Attachment 9)**.

The following table summarizes the results of the mercury study comparison and sediment mercury results in subdrainage areas incorporating historical and supplemental analyses.

Sediment Mercury Summary Statistics and Conder et al. (2015) NOEC Exceedances							
Drainage Area	Subdrainage Area	Detection Frequency	Min.	Max.	Arithmetic Mean	Median	95UCL
			mg/kg				
NDA	Duck Pond	44/45	0.0043	0.69	0.24	0.17	0.29
	Unnamed Ponds	23/23	0.0079	**11.4**	0.88	0.24	3.03
	Western Tributary	34/34	0.044	2.79	0.70	0.48	0.95
SDA	**Central Drainage Basin**	25/25	0.021	**25.4**	2.32	0.49	6.84
	Development Area Stream	11/15	0.011	0.70	0.13	0.06	0.35
	Maintenance Dynamite Area-East	44/44	0.017	11	1.02	0.46	2.13
	Maintenance Dynamite Area-West	38/39	0.005	**14.7**	1.05	0.25	2.88
	Maintenance NG Area	27/27	0.069	**27**	1.57	0.42	1.88
	Miscellaneous Offsite Streams – Upper	30/31	0.0043	4.14	0.50	0.14	0.92
	TNT-PETN-NG Ditches	22/25	0.014	7.51	0.62	0.25	1.49

Notes: Bold values indicate exceedance of Conder et al. (2015) spiked-sediment NOEC upper bound (11 mg/kg). Summary statistics incorporate historical and supplemental analyses.

In subdrainage areas where sediment mercury exceeded the Conder et al. (2015) NOEC upper-bound concentration (11 mg/kg), benthic invertebrate community surveys were performed to provide an additional LOE regarding potential risk (as detailed further in Section 5.1.1.2). These subdrainage areas are as follows:

- Unnamed Ponds
- Central Drainage Basin
- Maintenance Dynamite Area - West
- Maintenance NG Area

5.1.1.1.2.1.2.2 Methylmercury

In subdrainage areas where potential risk from mercury remained uncertain following ERAWP implementation (**Attachment 9**), supplemental surface water samples were collected and analyzed for total and dissolved MeHg. These subdrainage areas include:

- Unnamed Ponds
- Maintenance Dynamite Area – West
- Maintenance Dynamite Area – East

Results of total and dissolved MeHg analyses in surface water are provided in **Appendix C** and summarized in the table that follows.

Drainage Area	Subdrainage Area	Methylmercury (ng/L)			
		Total		Dissolved	
		Min.	Max.	Min.	Max.
NDA	Unnamed Ponds	0.49	3.1	ND	0.24
SDA	Maintenance – Dynamite Area – West	0.17	0.38	ND	
	Maintenance – Dynamite Area - East	0.05		ND	

As shown above, total MeHg across subdrainage areas ranged from 0.05 to 3.1 nanograms per liter (ng/L). Dissolved MeHg was not detected above reporting limits apart from one sample (0.24 ng/L) in Unnamed Ponds, suggesting low potential MeHg mobility and bioavailability to aquatic life in Maintenance – Dynamite Areas – East and West.

While no formal MeHg ESC are available for direct comparison, NJDEP's surface water ESC of 0.77 µg/L (770 ng/L) for total mercury is greater than three orders of magnitude above the sample result and represents a bioavailable MeHg fraction (dissolved:total MeHg) of approximately half (49.3%), as compared to its paired total MeHg sample. Alternatively, while total and dissolved MeHg in overlying water provides an additional LOE regarding potential risk to aquatic and benthic invertebrates, uncertainty arises when translating potential benthic risk from dissolved concentrations in overlying water to potential risk from direct porewater exposure. Thus, additional investigation of mercury in Unnamed Ponds is recommended despite this LOE.

5.1.1.1.2.1.3 Chromium

Potential risk to benthic invertebrates from sediment chromium remained uncertain (i.e., HQ_{LEL} greater than 1) in Maintenance - Dynamite Area - East following ERAWP implementation. As detailed in the ERASSM implementation memo (**Appendix C**), three sediment samples were collected and analyzed in July 2019 for total, trivalent [Cr(III)], and hexavalent chromium [Cr(VI)] in this subdrainage area. Chromium toxicity aquatic life is dependent on valence state, with Cr(VI) being considerably more toxic and bioavailable.

Sediment Cr(III) concentrations (range: 6.42 – 31.6 mg/kg) were equivalent to total chromium and Cr(VI) was not detected. Results of chromium speciation analysis indicated that sediment conditions in Maintenance - Dynamite Area – East favor the less toxic and less mobile Cr(III). As such, no further investigation of chromium is warranted in this subdrainage area.

5.1.1.1.2.1.4 Copper and Zinc

Surface water samples collected during ERAWP implementation (**Attachment 4**) were analyzed for total and dissolved copper and zinc in one subdrainage area (i.e., Unnamed Ponds) targeted for refinement in the ERAWP desktop evaluation (**Appendix A**).

In June 2016, water depths within Unnamed Ponds were less than three inches in the smaller of the two ponds, where only one sample was able to be collected and analyzed. Standing water

was present in the larger pond, and four samples were collected. In May 2018, an additional three samples were collected for dissolved zinc when standing water was present.

The table below summarizes surface water quality parameters and dissolved copper and zinc in Unnamed Ponds in June 2016 and May 2018.

Unnamed Ponds - Water Quality Parameters and Dissolved Copper and Zinc Summary				
Parameter	**Unit**	**Large Pond**	**Small Pond**	
		June 2016	**June 2016**	**May 2018**
Turbidity	NTU	12.5	71,000	12.4
Total Suspended Solids	mg/L	44	1,880	32.9
Hardness	mg/L $CaCO_3$	22.1	120	72
Hardness-dependent SWQS - Copper	µg/L	2.33	9.9	--
Hardness-dependent SWQS - Zinc	µg/L	31.7	133	86.2
Maximum Detected Dissolved Copper	µg/L	ND	4.4	--
Maximum Detected Dissolved Zinc	µg/L	8.7	**247**	35.7

In June 2016, high turbidity (71,000 NTU) caused by low water levels in the small pond likely contributed to the hardness-dependent SWQS exceedance for zinc in the single sample collected. Alternatively, samples collected in May 2018 measured considerably lower turbidity with no exceedances for zinc. As such, potential risk from dissolved copper and zinc in this subdrainage area is unlikely and no further evaluation is warranted.

5.1.1.1.2.2 Polycyclic Aromatic Hydrocarbons

Consistent with *Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: PAH Mixtures* (PAH EQP Guidance) (USEPA 2003c), equilibrium partitioning (EQP) analysis was used to evaluate the bioavailability of PAHs in sediment under given sediment conditions. EQP analysis requires analysis of 17 parent and 17 alkylated family PAHs (34 total constituents) to develop ESB toxic units (ESBTUs) to predict constituent concentrations in sediment interstitial (pore) water based on equilibrium partitioning between sediment organic carbon and water (USEPA 2003c).

Consistent with *Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: PAH Mixtures* (USEPA 2003c), equilibrium partitioning (EQP) analysis was used to evaluate the bioavailability of PAHs in sediment under given sediment conditions. EQP analysis requires analysis of 17 parent and 17 alkylated family PAHs (34 total constituents) to develop ESB toxic units (ESBTUs) to predict constituent concentrations in sediment interstitial (pore) water based on equilibrium partitioning between sediment organic carbon and water (USEPA 2003c).

The 34-PAH ESBTU is calculated as follows:

$$\sum ESBTU_{FCV} = \sum_{i} \frac{C_{OC,PAHi}}{C_{OC,PAHi,FCVi}}$$

Where,

FCV = Final Chronic Value

$C_{OC,PAHi}$ = organic carbon-normalized concentration of an individual PAH in sediment

$C_{OC,FCVi}$ = the critical organic carbon-normalized concentration of a PAH in sediment, as determined by the FCV

FCVs presented in the PAH EQP Guidance represent ESB toxicity endpoints for PAHs derived using National Water Quality Criteria Guidelines (Stephan et al. 1985).

The PAH EQP Guidance recognizes that many PAH datasets generated during stie characterization activities do not contain data for each of the 34 parent and alkylated family compounds. As such, the guidance establishes procedures and uncertainty factors for handling PAH datasets with fewer compounds represented. Specifically, these include 13-PAH datasets and 23-PAH datasets.

Consistent with NJDEP regulations, the SI and RI analyses for PAHs focused on the 17-PAH Priority Pollutant analyte list. To this end, the evaluation of historical PAH data relies on the 13-PAH datasets and application of a 95% uncertainty factor (95%UF) to calculate ESBTUs in eight subdrainage areas targeted for further evaluation in the ERAWP (Hercules 2016b) and listed below:

- Duck Pond
- Northeast Ponds
- Unnamed Ponds
- Maintenance – Dynamite Area – East
- Maintenance – Dynamite Area – West
- Maintenance – NG Area
- TNT-PETN-NG Ditches
- Miscellaneous Offsite Stream - Upper

The 95%UF of 11.5 (Table 6-1 of USEPA 2003) used in the 13-PAH ESBTUs is calculated as follows:

$$\frac{\Sigma ESBTU_{FCV,TOT}}{\Sigma ESTBTU_{FCV,13}}$$

Where,

$\sum ESBTU_{FCV,TOT}$ = the summation of FCV-based ESBTUs for a 34-PAH (total) mixture

$\sum ESBTU_{FCV,13}$ = the summation of FCV-based ESBTUs for a 13-PAH mixture

ESBTUs calculated using the 95%UF are presented in the Updated SSRP (**Attachment 9**).

Further, the Updated SSRP back-calculated a 13-PAH ESBTU benchmark of 8.83 that equated to a 34-PAH ESBTU of 1. This value was initially calculated through comparison to the Central Drainage Basin 34-PAH dataset. Initial PAH ESBTUs calculated using the SI/RI dataset were compared to ESBTUs calculated for the Central Drainage Basin, where ESBTUs were calculated using both the full 34 PAH dataset and the 13 PAH dataset with 95%UF to provide context and account for the overestimation of the 95%UF.

During ERASSM implementation (**Appendix C**), sediment samples were collected for analysis of 34 PAHs to refine PAH speciation and exposure estimates within subdrainage areas identified to have uncertain risk in the Updated SSRP. Supplemental sediment sampling for 34-PAH analysis was performed in three SDA subdrainage areas targeted for risk refinement, including:

- Maintenance – Dynamite Area - East
- Maintenance – Dynamite Area - West
- Miscellaneous Offsite Streams – Lower

These samples were used to confirm the benchmark value calculated for the Central Drainage Basin. In subdrainage areas where samples for 34-PAH analysis were not collected, the 13-PAH ESBTU benchmark value is used.

Results of this evaluation are presented in **Appendix C** and summarized in the following table.

Aquatic Exposure Areas Sediment PAHs Equilibrium-Partitioning Ecological Screening Benchmark Toxic Unit (ESBTU)				
Drainage Area	**Subdrainage Area**	**ESBTU Benchmark[a]**	**Maximum ESBTU**	**HQ**
NDA	Unnamed Ponds	8.83	4	≤ 1
	Duck Pond	8.83	4.6	≤ 1
	Northeast Ponds	8.83	2.3	≤ 1
SDA	Central Drainage Basin (ESBTU Benchmark Reference)	8.83 / 1	NA	NA
	Maintenance Dynamite Area - East	1	0.01	≤ 1
	Maintenance Dynamite Area - West	1	0.37	≤ 1
	Maintenance NG Area	8.83	6	≤ 1
	Miscellaneous Offsite Streams – Lower	1	**1.26**	≤ 1
	TNT-PETN-NG Ditches	8.83	5	≤ 1

Notes: ESBTU – Ecological Screening Benchmark Toxic Unit; [a]The ESBTU benchmark of 1 (unitless) represents a 34-PAH benchmark. The ESBTU benchmark of 8.83 (unitless) represents a 13-PAH benchmark with 95% certainty factor, equating to a 34-PAH benchmark of 1.

As shown above, results of these collective EqP PAH mixtures analyses indicate that potential risk to benthic invertebrates is possible (i.e., 34-PAH ESBTU greater than 1) in one subdrainage area (Miscellaneous Offsite Streams – Lower). A dataset evaluation was completed for Miscellaneous Offsite Streams – Lower to better understand the elevated ESBTU. Two 34-PAH samples were collected within this subdrainage area – one at SD-ERA-B16-MOSL-01 with an ESBTU of 1.26, and one at SD-ERA-C15-MOSL-01 with an ESBTU of 0.01. SD-ERA-B16-MOSL-01 is located adjacent to Rt 46, and the elevated ESBTU is likely attributable to run-on from offsite sources. Therefore, this elevated ESBTU is not considered of significant risk for Miscellaneous Offsite Streams – Lower.

5.1.1.1.2.3 Benthic Invertebrates

The ERAWP desktop evaluation identified NDA and SDA subdrainage areas where potential risk to benthic invertebrate communities remained uncertain following the 2016 EE/ERA. In this evaluation, benthic invertebrate EPCs were compared to Lowest Effects Level (LEL) and Severe Effects Level (SEL) criteria (see Section 6.2) considered protective of benthic organisms. These LEL- and SEL-based HQs (HQ_{LELs} and HQ_{SELs}, respectively) were calculated to provide a bounding estimate of potential risk. Where subdrainage HQ_{LELs} were greater than 1, additional LOEs were evaluated, including acid-volatile sulfide/simultaneously extracted metals (AVS/SEM) analyses at 30 sediment sampling locations in six subdrainage areas supplemented with total organic carbon (TOC) surrogate evaluations in seven remaining subdrainage areas (as detailed in the following section).

Further, the Updated SSRP identified NDA and SDA subdrainage areas where potential risk to benthic invertebrate communities remained uncertain following ERAWP implementation in June

2016. Where LOEs indicated potential risk to benthic invertebrates (as detailed in **Attachment 9**), supplemental LOEs were evaluated, including AVS/SEM analyses at 3 sediment sampling locations in an additional subdrainage area (Maintenance Dynamite Area – East) and benthic invertebrate community sampling in five subdrainage areas.

The following sections summarize the results of AVS/SEM analyses, TOC surrogate evaluations, and benthic invertebrate community sampling.

5.1.1.1.2.3.1 AVS/SEM and Total Organic Carbon

In the presence of adequate quantities of sulfide, divalent metals (i.e., Cd, Cu, Pb, Ni, Zn) bind in sulfide complexes and are not bioavailable. In the absence of sufficient sulfide (or excess metals), metals will bind to organic carbon as well. A comparison of sulfide and organic carbon content relative to divalent metals concentrations can be used as an indicator of potential bioavailability, and toxicity, to benthic communities (ITRC 2011). This method gives a better indication of sediment toxicity to benthic organisms than total metals sampling by measuring the bioavailable fraction of metals present. Ratios less than 130 micromoles per gram organic carbon (µmoles/gOC) indicate that toxicity to the benthic community is unlikely; between 130 and 3,000 µmoles/gOC indicate that toxicity is possible, and over 3,000 µmoles/g indicate that toxicity is likely (USEPA 2005).

In subdrainage areas not evaluated via AVS/SEM, percent total organic carbon (TOC%), correlative with AVS/SEM (ITRC 2011), was used as a surrogate. Where TOC% exceeds 0.1%, potential bioavailability, and toxicity, of divalent metals to benthic invertebrate communities is considered unlikely.

Results of AVS/SEM analysis and TOC% surrogate evaluation are detailed further in **Appendix C** and the Updated SSRP (**Attachment 9**) and are summarized in the table that follows.

Sediment AVS/SEM and Total Organic Carbon Summary Statistics							
Drainage Area	Subdrainage Area	Maximum (∑SEM-AVS) fOC	%TOC[b]				
			Min.	Max.	Median	Arithmetic Mean	Frequency ≤0.1% TOC
		µM/gOC	Percent				
NDA	Unnamed Ponds	14.4	11.4	40	22	22.28	0/5
	Duck Pond[a]	--	0.086	37	6.75	10.6	2/44
	Eastern Tributary[a]	--	0.63	7.3	1.55	2.565	0/6
	Western Tributary	--	19.2	24.4	21.8	21.8	0/2
	Northeast Ponds	--	3.95	22.7	10.5	12.38	0/3
SDA	Development Area Stream[a]	--	0.091	5.2	1.55	1.91	1/16
	TNT-PETN-NG Ditches	59	2.89	41.6	22.25	22.25	0/2
	Maintenance NG Area	23.9	0.0695	13.2	4.71	5.99	1/4
	Maintenance -Dynamite Area - West	20	8.34	14.2	10.2	10.91	0/3
	Maintenance -Dynamite Area - East	43.5	0.982	22.6	5.34	7.07	0/7
	Central Drainage Basin	0.24	0.478	45.6	18.2	21.52	0/11
	Miscellaneous Offsite Streams - Upper	**1,100**	0.0767	8.99	2.85	3.47	1/5
	Miscellaneous Offsite Streams - Lower	--	0.42	21.3	5.06	7.96	0/4

Notes: Bolded values indicate (∑SEM-AVS)/fOC exceeding 130 µM/gOC, where benthic invertebrate toxicity is uncertain
µM/gOC - micromoles per gram organic carbon, fOC – fraction organic carbon
[a]TOC data from Duck Pond, Eastern Tributary, and Development Area only available in 0.5-1.0 ft bgs depth intervals.
[b]Where duplicate samples were collected, the lower TOC% of the parent and duplicate sample is used for summary statistics.

The AVS/SEM ratio of 1,100 uM/gOC in Miscellaneous Offsite Steams – Upper is an artifact of both very low sulfide and TOC, and low metals concentrations. The concentrations of each divalent metal at the location of the maximum AVS/SEM ratio were each less than 0.1 mg/kg and less than sediment ESC. As such, despite the high ratio (a relative measure), metals concentrations (an absolute measure) are not expected to cause unacceptable risk at this single sample location. Further, similar results were observed at sample locations proximate to this AVS/SEM sample location. Similarly, the metals concentrations at Duck Pond and Development Streams are below ESB in locations of low TOC. Therefore, risk is unlikely in these areas as assessed by this method.

5.1.1.1.2.3.2 Biodiversity Indices

Flowing and/or non-flowing aquatic habitat in five SDA subdrainage areas were targeted for benthic invertebrate community sampling as shown in the table below. In addition, two samples were collected from each of two on-site reference locations in the Development Area and

Northeast Ponds. These locations occur near the perimeter of the Facility and represent local, ambient conditions beyond the influence of former Facility operations. Reference sample locations targeted similar substrate types and hydrological conditions as the sample locations in the five subdrainage areas.

Subdrainage areas sampled for benthic invertebrate community data are shown in **Figures 3-3** and in the table below.

Benthic Invertebrate Community Sampling		
Drainage Area	**Subdrainage Area**	**No. of Sample Locations**
Flowing Aquatic Habitat		
SDA	Development Area Stream (Reference)	2
	Central Drainage Basin	2[a]
	Maintenance Dynamite Area - West	2
	Maintenance NG Area	2
	TNT-PETN-NG Ditches	1
Non-flowing Aquatic Habitat		
NDA	Northeast Ponds (Reference)	2
SDA	Unnamed Ponds	3
	Central Drainage Basin	2[a]

[a]A total of two benthic community samples were collected in the Central Drainage Basin. This subdrainage area contains habitat representative of both flowing and non-flowing habitat.

August 2019 implementation of the ERASSM field sampling plan and results of benthic invertebrate identification and enumeration are provided in **Appendix C**. These results were used to calculate biodiversity indices for flowing and non-flowing subdrainage areas.

Benthic community analysis of flowing and non-flowing aquatic habitat relied on common statistical metrics and the NJDEP's high gradient macroinvertebrate index (HGMI). Specific information regarding each analysis follows:

- Shannon-Weiner Diversity Index (H') – measures diversity within the benthic invertebrate community. Typical H' values fall between 1.5 and 3.5 and increase as both the richness and the evenness of the community increases. A lower (closer to 0) H' value indicates a lower level of diversity. Inversely, a higher H' value indicates a greater number of species within the community and a more even distribution of the number of individuals across species.

- Pielou's Species Evenness Index (J') – measures evenness within the benthic invertebrate community. The J' value is constrained between 0 and 1. A lower J' value (closer to 0) indicates less evenness between species in communities and the likely presence of a

dominant species. A higher J' (closer to 1) value indicates less variation, and thus greater continuity or evenness, in communities between the species.

- Abundance – measures the number of individuals in each benthic invertebrate community sample. In this case, abundance is calculated by averaging the number of individuals in the replicates across each individual sample location.

- Effective Number of Species (ENS) – measures the number of equally-common species within a community. The ENS represents the real biodiversity and allows for comparison of biodiversity with other communities

The following metrics (Ludwig & Reynolds 1988) were calculated for each benthic invertebrate community sample location as follows:

$$H' = - \sum_{i=1}^{m} (n/N) * \ln(n/N)$$

Where,

n = number of individuals per taxon
N = total number of individuals
m = number of taxa

$$J' = H'/\ln(S)$$

Where,

S = number of species in the benthic invertebrate community sample

And,

$$ENS = e^{H'}$$

The HGMI was calculated at each sample location according to NJDEP's *Standard Operating Procedures Ambient Biological Monitoring Using Benthic Macroinvertebrates* (2007). The HGMI is an indication of water quality that is based on richness and abundance of pollution intolerant and tolerant species.

Calculated biodiversity indices are presented in **Appendix C** and summarized in the following tables.

Benthic Invertebrate Biodiversity Indices						
Drainage Area	Subdrainage Area	HGBI	H'	J'	ENS	Abundance
		Lower Bound				
Flowing Aquatic Habitat						
SDA	Development Area Stream (Reference)	20.1	3.52	0.68	34.0	32.0
	Central Drainage Basin	25.2	**1.45**	**0.35**	**4.26**	65.0
	Maintenance Dynamite Area - West	22.0	**2.46**	**0.57**	**11.6**	178.3
	Maintenance NG Area	**14.1**	**1.64**	**0.39**	**5.22**	74.0
	TNT-PETN-NG Ditches	26.4	3.60	0.77	36.4	54.0
Non-flowing Aquatic Habitat						
NDA	Northeast Ponds (Reference)	19.5	1.93	0.48	6.86	181.7
SDA	**Unnamed Ponds**	**7.65**	**1.72**	**0.37**	**5.59**	**37**
	Central Drainage Basin	25.2	**1.45**	**0.35**	**4.26**	**65**

Notes: Bolded values indicate biodiversity indices below Facility-specific flowing or non-flowing habitat reference lower bound.

Comparison of benthic invertebrate samples identified benthic invertebrate communities with Shannon-Weiner Diversity Index scores lower than those represented by reference locations, including flowing aquatic habitat samples in the Maintenance NG Area, Maintenance Dynamite Area – West, and Central Drainage Basin) and non-flowing aquatic habitat samples in the Central Drainage Basin and Unnamed Ponds, though HGBI scores were lower than reference locations only at Maintenance NG Area within the flowing aquatic habitat.

5.1.1.1.2.3.3 Benthic Invertebrate Community Summary

As detailed in previous sections, implementation of the ERAWP and ERASSM field sampling plans resulted in multiple LOEs regarding potential risk to benthic invertebrates.

Sediment COPECs were initially compared to LELs and SELs considered protective of benthic invertebrates, resulting in HQ_{LELs} and HQ_{SELs}. Where HQ_{LELs} were greater than 1, additional LOEs were evaluated (as shown in the table below). These supplemental LOEs are incorporated in risk characterization of aquatic exposure areas (as discussed in Section 7.2).

The following table summarizes the results of supplemental LOEs for each NDA subdrainage area. **Tables 4-10 and 4-11** additionally track the COPEC progression through the various evaluation methods.

NDA Subdrainage Areas - Benthic Invertebrate Risk Evaluation						
Risk Evaluation Method	**Notes**	**Unnamed Ponds**	**Duck Pond**	**Eastern Tributary**	**Western Tributary**	**Northeast Ponds**
ESC Screen	b	+	+	+	+	+

[a]The AVS/SEM and Surrogate TOC% evaluation method represents a LOE for divalent metals including cadmium, copper, lead, nickel, and zinc.
[b]Evaluated in Appendix F of KJ (2016) (**Attachment 1**)
[c]Evaluated during ERASSM implementation
[d]Evaluated in Updated SSRP (**Attachment 9**)

As shown above, the weight-of-evidence (WOE) in the NDA subdrainage areas indicates acceptable risk within four subdrainage areas. Alternatively, the WOE for the Unnamed Ponds indicates potential unacceptable risk for arsenic and mercury in sediment. Additional investigation into Unnamed Ponds for these COPECs is recommended.

The table that follows summarizes the results of supplemental LOEs for each NDA subdrainage area. **Tables 4-10 and 4-11** additionally track the COPEC progression through the various evaluation methods.

[b]Evaluated in Appendix F of KJ (2016) (**Attachment 1**)
[c]Evaluated during ERASSM implementation
[d]Evaluated in Updated SSRP (**Attachment 9**)

The WOE in SDA subdrainage areas indicates acceptable risk within five subdrainage areas. Alternatively, the WOE for the Central Drainage Basin, Maintenance NG Area, and Maintenance – Dynamite Area - West indicates potential unacceptable risk for arsenic, lead, mercury, and/or silver in sediment. Additional investigation into these SDA subdrainage areas for these COPECs is recommended.

5.1.2 Upper-Trophic Level Wildlife Exposure

To evaluate potential exposure of upper-trophic-level wildlife (e.g., mammals and birds) to COPECs, a food web model is used to estimate the daily dietary dose to each receptor. This equation estimates the dose of a COPEC through dietary ingestion of soil/sediment and prey tissue items.

Generally, only bioaccumulative COPECs (identified in **Table 4-4**) are modeled for upper-trophic-level wildlife, as these constituents accumulate in prey tissue and can be transferred up the food web via ingestion. As a result, chronic effects to survival, growth, and reproduction are the general endpoints of an ERA and are evaluated through the dietary ingestion pathway. Although upper-trophic level wildlife may also be exposed to non-bioaccumulative constituents via other pathways (e.g., inhalation, dermal exposure), these exposure pathways are generally considered *de minimis* and are not quantitatively evaluated in ecological risk assessments (Suter 2007).

For this ERA, E&E constituents (although not considered bioaccumulative) were also run through food web models due to their direct ties to the Facility operational history and presence in soil at the Facility.

The food web model to estimate potential exposure to wildlife is as follows:

$$DDD = \frac{\{[(IR_f \times C_f) + (IR_s \times C_s)] \times AUF\}}{BW}$$

Where:

DDD	=	Daily dietary dose of COPEC (mg/kg per day)
C_f	=	Concentration of a COPEC in food (mg/kg)
IR_f	=	Daily ingestion of food (kilograms per day [kg/day])
C_s	=	Concentration of a COPEC in soil/sediment (mg/kg)
IR_s	=	Daily incidental ingestion rate of soil/sediment (kg/day)
AUF	=	Area use factor (unitless)
BW	=	Body weight (kilograms)

5.1.2.1 Exposure Parameters

Exposure parameters for upper-trophic-level wildlife receptors include body weight, dietary composition, dietary and incidental media (e.g., soil and/or sediment) ingestion rates, bioavailability, bioaccessibility, and area use factors (AUFs). When available, these values are obtained via direct or indirect measurements at the Facility (as detailed in the following sections). Otherwise, values were derived from literature, including the USEPA's *Exposure*

Factors Handbook (USEPA 1993b), Sample and Suter (1994), Nagy (2001), USEPA (2007a, 2007b), and Beyer et al. (1994). Literature-derived exposure parameters were selected from a hierarchy of sources to preferentially select values based on measured data (e.g., Nagy 2001) instead of modeled data, and more recent sources instead of historical information.

Table 5-10 presents the selected exposure parameters for the terrestrial and aquatic receptor species.

5.1.2.1.1 Body Weights

Body weights were selected from Nagy (2001) when available. If unavailable, body weights were calculated as the mean adult and juvenile body weights provided in USEPA (1993b). Incorporating juvenile body weights is a conservative approach because it is protective of the juvenile portion of the population in addition to the adults.

5.1.2.1.2 Dietary Composition

In the 2016 EE/ERA, prey items with a potential to bioaccumulate COPECs were selected to represent the entirety of a receptor's diet. Thus, the American robin's diet was assumed to consist solely of earthworms. However, USEPA (1993b) and Martin et al. (1951) indicate that the diet of American robins consists of both plants and invertebrates. As such, the American robin is re-evaluated using a study-based diet of plants, comprising 62.5 percent of its diet, and invertebrates, comprising 37.5 percent of its diet (USEPA 1993b; Martin et al. 1951).

Tree swallows also have a varied diet of aerial insects, seeds and plants. Tree swallows are the only member of the swallow family that also feed on berries when insects are limited. This trait enables tree swallows to overwinter in harsher climates and make early spring returns to their breeding habitat. Beal (1918) found the following results by analyzing stomach contents of adults collected during different seasons at various locations: 80 percent of diet was animal, 20 percent vegetable. As such, their dietary composition has been modified to reflect 80 percent invertebrates and 20 percent plants (Beal 1918, Robertson et al. 1992).

5.1.2.1.2.1 Prey Tissue Concentrations

The 2016 EE/ERA relied on soil-to-tissue bioaccumulation factors to estimate prey item tissue concentrations from soil data. To reduce uncertainty associated with the modeled relationship between soil and tissue concentrations, aerial insect tissue was collected from specific areas of the Facility and used as a direct measurement of concentrations of copper and lead in dietary matter in aquatic exposure area insectivore models (i.e., tree swallow and little brown bat). The maximum concentration identified across all subdrainage areas within the NDA or SDA, respectively, were used in place of the biota-sediment accumulation factors (BSAFs) for copper and lead within the aquatic food web models for tree swallow (**Tables 7-13 and 7-22**) and little brown bat (**Tables 7-16 and 7-25). Appendix E** presents the full aerial insect tissue dataset.

In the absence of these Facility-specific tissue concentrations, soil bioaccumulation factors (BAFs) and biota-sediment accumulation factors (BSAFs) were used to estimate COPEC concentrations in biological tissue. These factors relate the concentration in environmental medium to which receptors are exposed to a tissue concentration. The bioavailability of each COPEC varies relative to physical and biological Facility-specific conditions; therefore, the use of BSAFs and BAFs introduces considerable uncertainty. BAFs and BSAFs are discussed below and in Section 8. Bioaccumulative compounds were selected from USEPA (2000).

5.1.2.1.2.1.1 Bioaccumulation Factors

BAFs are available for several COPECs to estimate concentrations in terrestrial organisms (i.e., soil invertebrates [earthworms], terrestrial plants, and mammals) based on concentrations in soil. Although bioaccumulation can vary substantially by species and site, these factors provide some bounding estimates of potential bioaccumulation to help assess potential risk and the need for additional Facility-specific bioaccumulation information.

BAFs may either be a simple factor by which the soil EPC is multiplied or based on a linear equation that incorporates the soil EPC.

Sources of BAFs include:

- Screening-Level Ecological Risk Assessment Protocol for Hazardous Waste Combustion Facilities – Appendices C through E (USEPA 1999)
- Guidance for Developing Ecological Soil Screening Levels (Eco-SSLs), including Attachment 4-1 – Exposure Factors and Bioaccumulation Models for Derivation of Wildlife Eco-SSLs (USEPA 2007a)
- Development and Validation of Bioaccumulation Models for Earthworms (Sample et al. 1998a)
- Development and Validation of Bioaccumulation Models for Small Mammals (Sample et al. 1998b)
- Empirical Models for the Uptake of Inorganic Chemicals from Soil by Plants (Bechtel Jacobs 1998)
- Literature-derived Bioaccumulation Models for Energetic Compounds in Plants and Soil Invertebrates (CH2M HILL 2005)
- Ecotoxicology of Explosives (Sunahara et al. 2009).

When multiple BAFs are available, BAFs based on a wide range of studies or a large dataset were preferentially selected over those developed based on more limited information. Terrestrial BAFs are presented in **Table 5-6**; the resulting estimated tissue concentrations are presented in **Table 5-7**.

5.1.2.1.2.1.2 Biota-Sediment Accumulation Factors

BSAFs were available for several COPECs to estimate tissue concentrations in aquatic organisms (i.e., fish and benthic invertebrates) based on concentrations in sediment. While these values vary by species and site, they provide some bounding estimates of potential bioaccumulation to help assess potential risk and the need for additional Facility-specific bioaccumulation information.

Aquatic tissue concentrations estimated with BSAFs incorporate the organic carbon of the sediment and the percent lipid of the organism, according to the following equation:

$$C_{tissue} = \left(\frac{BSAF \times C_{sed} \times f_{lipid}}{f_{oc}}\right)$$

Where:

C_{tissue} = COPEC concentration in tissue (invertebrate or fish) (milligrams per kilogram [mg/kg])

BSAF = Biota-sediment accumulation factor (kilogram organic carbon per kilogram lipid [kg_{oc}/kg_l])

C_{sed} = COPEC concentration in sediment (mg/kg)

f_{lipid} = Fraction of lipid in tissue (kg_{oc}/kg_l)

f_{oc} = Fraction of organic carbon in sediment (kg_{oc}/kg_l)

Sources of BSAFs include:

- USEPA's Mid-Atlantic Ecology Division BSAF database (http://www.epa.gov/med/Prods_Pubs/bsaf.htm) (USEPA 2009)
- U.S. Army Corps of Engineers (USACE) BSAF database (http://el.erdc.usace.army.mil/bsafnew/) (USACE ERDC EL 2011[8])
- Empirical Models for the Uptake of Inorganic Chemicals from Soil by Plants (Bechtel Jacobs 1998)
- Literature-derived Bioaccumulation Models for Energetic Compounds in Plants and Soil Invertebrates (CH2M HILL 2005)
- Screening-Level Ecological Risk Assessment Protocol for Hazardous Waste Combustion Facilities – Appendices C through E (USEPA 1999).

Average lipid content was assumed to be 5% for fish and 3% for invertebrates, based on average lipid values from the USACE's BSAF database (USACE ERDC EL 2011). Average TOC content for the NDA and SDA of 13 and 6 percent, respectively, were used to calculate tissue concentrations.

BSAFs required for fish tissue concentration estimates were unavailable for several COPECs. As a result, BSAFs for invertebrates are used in lieu of BSAFs for fish tissue. Furthermore, BSAFs do not exist for aquatic plants; therefore, terrestrial BAFs were used. In other cases where BSAFs were unavailable, the BAF for soil invertebrates was selected as a conservative factor to estimate aquatic invertebrate and fish tissue concentrations.

The aquatic BSAFs are provided in **Table 5-8**; resulting tissue concentrations are provided in **Table 5-9**.

5.1.2.1.3 Dietary Ingestion Rates

Ingestion rates are generally presented on either a dry or fresh (wet) weight basis. Nagy (2001) presents actual dietary ingestion data for both wet and dry weight dietary tissue. Available values from Nagy (2001) were selected instead of values from other sources presenting only wet or dry weights that require conversion factors to obtain the corresponding wet or dry weight value. When values were not available in Nagy (2001), wet weight ingestion rates were selected from USEPA (1993b) and converted to dry weight ingestion rates using the following equation:

[8] This website is down for construction indefinitely.

$$IR_{dw} = IR_{ww} \times (1 - Percent\ moisture)$$

Where:

IR_{dw}	=	Ingestion rate (dry weight)
IR_{ww}	=	Ingestion rate (wet weight)
Percent moisture	=	Invertebrates: 84 percent, tissue: 68 percent; plants: 85 percent (USEPA 2007a)

5.1.2.1.4 Soil/Sediment Ingestion Rates

In the 2016 EE/ERA, soil/sediment ingestion rates were preferentially selected from Beyer et al. (1994) for muskrat, American robin, northern bobwhite, red fox, and white-tailed deer. Soil ingestion rates for red-tailed hawk and short-tailed shrew are from USEPA (2007a). If literature values less than 2 percent soil ingestion (by weight) were noted, or if no soil/sediment ingestion rate could be found for a particular species, a conservative value of 2 percent was used. The percent of soil/sediment ingested was multiplied by the dry weight ingestion rate to obtain the rate in kg/day.

Recent data indicates that the percentage of soil in the American robin's diet is higher than that assumed in the 2016 EE/ERA (10%), which was based on soil ingestion for a surrogate species, the woodcock. Hansen et al. (2011) concludes that American robins consume approximately 20% of soil in their diets, so a soil ingestion rate of 20% was incorporated into the model.

5.1.2.1.5 Bioaccessibility of Lead

The 2016 EE/ERA conservatively assumed that COPECs are completely absorbed into an organism's gastrointestinal tract and enter the bloodstream where they can cause adverse effects. Kaufman et al. (2007) provide gastric models for both birds and mammals to evaluate the proportion of lead that mobilizes into the digestive juices (bioaccessible fraction) from soil, earthworms, and vegetation collected at a rifle and pistol range.

Results for the avian gastric model suggest that the bioaccessible fraction of lead was 53 and 73 percent in soil and earthworm tissue, respectively Kaufman et al. 2007). For the mammalian model, the bioaccessible fraction of lead was 66, 77 and 50 percent in soils, earthworm tissue, and unwashed vegetation, respectively. As such, results from Kaufman et al. (2007) were incorporated into the upper trophic level food web models (**Attachment 8**).

5.1.2.1.6 Area Use Factor

The area use factor (AUF) is an input parameter representing the fraction of time that a wildlife receptor spends in an area based on factors such as proportion of a receptor's foraging range that is encompassed by the area or migratory patterns.

In the 2016 EE/ERA, each wildlife species was assumed to forage only in the exposure area, incorporating an AUF of 1 (i.e., 100% of the time). However, mammals and birds may forage beyond the boundaries of the exposure areas or the Facility itself. For instance, tree swallows, American robins, red-tailed hawks, and great blue herons migrate from their northerly breeding grounds in the autumn and return in the spring (Sample et al. 1997; USEPA 1993b), reducing the amount of time that could be spent at the Facility.

In addition, birds and mammals have a species- and or sex-specific foraging or home range, which is the distance from their nest or den they will travel to forage for food. Frequently, this area is larger than the exposure area or Facility, which would result in an AUF less than one for birds and mammals using the Facility as part of their foraging territory. Specific habitat types may be avoided when preferrable habitat is available. Such is the case for tree swallows and little brown bats, where open areas are preferrable for foraging activities and flight obstructions (e.g., trees and dense shrubs) are avoided (Sample et al. 1997; USEPA 1993b). Further, foraging range or territory size may also be reduced during breeding periods and/or during incubation and nesting periods in the case of avian receptors.

These different use patterns are accounted for within the AUF calculation. The following equation serves as a general example:

$$Area\ Use\ Factor = \left(\left(\left(\frac{Home\ range_{NB}}{Habitat\ area}\right) * Time_{NB}\right) + \left(\left(\frac{Home\ range_{B}}{Habitat\ area}\right) * Time_{B}\right)\right) * Seasonal\ Use$$

Where:

Habitat area	=	Useable habitat area in the Facility (acres)
Home range$_{NB}$	=	Non-breeding home range or territory (acres)
Time$_{NB}$	=	Non-breeding time (days per year)
Home range$_{B}$	=	Breeding home range or territory (acres)
Time$_{B}$	=	Breeding time (days per year)
Seasonal use	=	Northern range time (days per year); only applicable to migratory receptors

The specifics of this equation vary by receptor. For example, the breeding home range and breeding time parameters may also incorporate periods of reduced home range size associated with incubation, nesting, and/or time spent as a family unit (e.g., northern bobwhite). Where home range or territory size varies by sex, the more conservative of the male and female AUF is used.

The following sections detail literature-derived life history characteristics for upper-trophic-level receptors in terrestrial and aquatic exposure areas and specify how these characteristics were incorporated in AUF calculation.

5.1.2.1.6.1 Terrestrial Exposure Area Receptors

The following sections detail the rationale for receptor-specific AUFs in the terrestrial exposure area. Terrestrial receptor AUFs are also presented in the summary table below.

Terrestrial Receptor Species	Area Use Factor
Birds	
American robin	0.67
Northern bobwhite quail	1
Red-tailed hawk	0.5
Mammals	
Short-tailed shrew	1
White-tailed deer	0.67
Red fox	1

Available habitats considered in the AUF calculations within the terrestrial exposure area are summarized below:

Habitat Type	Size (acres)
Shrubland	11.8
Grassland/Forb Complex	167
Forest	162.5
Total Terrestrial Exposure Area	**341**

5.1.2.1.6.1.1 American robin

For the American robin, an AUF of 0.67 is used. The average territory size of adult American robins is 1 ac (range: 0.3-2.1 ac) with an average reported foraging home range of 0.4 ac while feeding nestlings (USEPA 1993b). Adult robins will incubate for 12.5 days [d] and nest for 13.4 d. (approximately 26 d total). Terrestrial foraging habitat includes forests, open woodlands, orchards, and open areas (USEPA 1993b).

As such, this AUF assumes adult robins forage and nest in shrubland, grassland/forb complex, and forested habitat in the terrestrial exposure area (341 ac) for eight months of the year, incubating and nesting in the Facility for approximately 30 d, but migrate out of the area for the remainder of the year (USEPA 1993b).

5.1.2.1.6.1.2 Northern bobwhite quail

Northern bobwhite quail are non-migratory, anticipated to spend 100% of the year within their breeding and foraging home range. As such, an AUF of 1 is used.

Adult quail have an average pre-incubation and breeding home range of 8.9 and 16.8 ac, respectively (USEPA 1933b). During the breeding season (May-August; 1 clutch/year average), mated males average 18.8 ac, while females average 15.8 ac during nesting and 38.5 ac during post-nesting. Clutches incubate for 23 d and family units, when not lost to predation, remain intact

through the summer. During winter, average adult home ranges are approximately 16.8 ac. Grasslands, fallow, and pastures are preferred nesting habitats. Adult quail forage in open areas, whereas shrubby thickets are used for daytime cover.

As such, this AUF assumes adult quail nest and forage in shrubland and grassland/forb complex habitat in the terrestrial exposure area (179 ac) throughout the year, where adults incubate one clutch for 23 d in May, and nesting and foraging occur as a family unit post-incubation until the end of August (USEPA 1993b).

5.1.2.1.6.1.3 Red-tailed hawk

For the red-tailed hawk, an AUF of 0.5 is used. Breeding adults are reported to have an average territory size of 148 and 4,374 ac in spring and fall, respectively (USEPA 1993b). Terrestrial red-tailed hawk habitat can range from woodlands, pastures, and prairies to deserts, where a mixed landscape of open areas for foraging and woodlands for nesting and perching is preferred.

As such, this AUF assumes that adult red-tailed hawks forage and nest in shrubland, grassland/forb complex, and forested habitat in the terrestrial exposure area (341 ac) for 6 months of the year (i.e., spring and summer). For two months in fall, these usable terrestrial habitat types represent 7.8% of the red-tailed hawk's territory, while the remainder of fall and winter (four months) are spent away from the Facility in their southern migratory range.

5.1.2.1.6.1.4 Short-tailed shrew

For the short-tailed shrew, an AUF of 1 is used, consistent with the 2016 EE/ERA. Short-tailed shrews do not undergo torpor so they are active in their territory year-round (USEPA 1993b). Breeding also occurs year-round, with an average home range size of 0.96 ac across all seasons. Short-tailed shrews occupy a wide variety of terrestrial habitats, nesting underground in the top 10 cm of soil, and are common in areas with abundant vegetative cover.

As such, this AUF assumes that adult short-tailed shrews forage and nest in shrubland, grassland/forb complex, and forested habitat in the terrestrial exposure area (341 ac) throughout the year. In lieu of modeling 351 different 1-acre home ranges, Section 5.1.1.1.2 presents an initial evaluation and framework for assessing risks in areas of higher COPEC concentrations at a scale commensurate with a short-tailed shrew home range.

5.1.2.1.6.1.5 White-tailed deer

For white-tailed deer, an AUF of 0.67 is used. Annual home ranges of sedentary populations average 146 ac (Smith 1991). Northern populations of white-tailed deer have larger and less stable home ranges than southern populations, where seasonal migrations are common and variable according to snow depth, averaging 15.6 to 23.2 km [188,921 - 417,838 ac] (Smith 1991). Females and young move directly between seasonal ranges, while adult males tend to meander. White-tailed deer historically inhabit brushy and woodland areas.

As such, this AUF is based on adult male white-tailed deer, given their tendency to meander during seasonal migrations. It is assumed that browse and breeding grounds include shrubland and forested habitat in the terrestrial exposure area (174 ac), representing 100% of their home range for eight months of the year and less than 0.1% of their seasonal migration range for four months of the year.

5.1.2.1.6.1.6 Red fox

For red foxes, an AUF of 1 used, consistent with the 2016 EE/ERA. Red foxes do not undergo torpor or hibernation, so they are active in their territory year-round, averaging 1,772 and 237 ac for male and female adults, respectively (USEPA 1993b). Red foxes occupy a wide variety of terrestrial habitats, including cropland, brush, pastures, hardwood stands, and coniferous forests, preferring areas with broken and diverse upland habitats.

As such, this AUF is based on adult female red foxes, given their reduced territory size compared to males. It is assumed that red foxes hunt and den in in shrubland, grassland/forb complex, and forested habitat in the terrestrial exposure area (341 ac) throughout the year.

5.1.2.1.6.2 Aquatic Exposure Area Receptors

The following sections detail the rationale for receptor-specific AUFs within the NDA and SDA. AUFs were evaluated for each overall drainage area, then applied to each subdrainage area. Aquatic receptor AUFs are also presented in the summary table below.

Aquatic Receptor Species	Area Use Factor by Drainage Area	
	NDA	SDA
Birds		
Tree swallow	0.004	0.007
Mallard duck	0.17	0.07
Great blue heron	0.04	0.02
Mammals		
Little brown bat	0.25	0.25
Muskrat	1	1
Mink	1	1

Available habitats considered in the AUF calculations within the aquatic exposure areas are summarized below:

Habitat Type	Size (acres)	
	NDA	SDA
Forested Wetlands	15.8	40.7
Emergent Wetlands	16.5	30
Flowing and Non-flowing Aquatic Areas	12.6	4.6
Total Aquatic Exposure Area	**44.9**	**75.3**

5.1.2.1.6.2.1 Tree swallow

For the tree swallow, AUFs of 0.004 and 0.007 were incorporated for the NDA and SDA, respectively. Tree swallows will forage up to 60 kilometers [km] (2,794,696 ac) prior to incubation (Sample et al. 1997). However, during incubation (15 d) and nesting (22 d), foraging range is reduced, where females will travel up to 3 km (6,987 ac) and males up to 5 km (19,408 ac). Tree

swallows require open areas that do not inhibit flight activity, including marshes, bodies of water, and riparian edge habitat (Sample et al. 1997).

As such, these AUFs are based on adult female tree swallows, given their reduced foraging and home range compared to adult males. It is assumed that female adults forage in emergent wetlands and flowing and non-flowing aquatic habitat in the aquatic exposure areas for eight months of the year, incubating and nesting in the Facility for 37 d, but migrate out of the area for the remainder of the year (four months). Calculated AUFs were then multiplied by a factor of ten to account for uncertainty in aquatic habitat patch fidelity.

5.1.2.1.6.2.2 Mallard duck

For the mallard duck, AUFs of 0.17 and 0.07 were incorporated for the NDA and SDA, respectively. Mallards are migratory, arriving from their wintering grounds in March and departing in August through November (USEPA 1993b). Mallards have an average total home range of 1,156 ac for females and 1,532 ac for males, requiring dense grassy vegetation for nesting and preferring seeded cover fields and idle grassland. Nests are usually located within a few kilometers of water (USEPA 1993b).

As such, these AUFs are based on adult female mallard ducks, given their reduced home range compared to adult males. It is assumed that female adults forage in emergent wetlands and flowing and non-flowing aquatic habitat in aquatic exposure areas for eight months of the year (suitable aquatic habitat area; NDA = 19 ac, SDA = 12.1 ac), but migrate out of the area for the remainder of the year (four months). Calculated AUFs were then multiplied by a factor of ten to account for uncertainty in aquatic habitat patch fidelity.

5.1.2.1.6.2.3 Great blue heron

For the great blue heron, AUFs of 0.04 and 0.02 are used for the NDA and SDA respectively. In the northern part of its range, great blue herons are migratory, leaving their breeding grounds by October or November and returning between February and April (USEPA 1993b). For breeding adults, foraging distance from colonies averages 3.1 km (7,460 ac). Great blue herons inhabit a variety of freshwater areas, including freshwater lakes and rivers, occasionally foraging in wet meadows and pastures. Heronries are typically close to foraging grounds, where tall trees are preferred over short trees and bushes for nests.

As such, these AUFs assume that adult herons nest and forage in forested and emergent wetlands and flowing and non-flowing aquatic habitat in aquatic exposure areas for eight months of the year (suitable aquatic habitat area; NDA = 24.4 ac, SDA = 20.2 ac) but migrate out of the area for the remainder of the year (four months). Calculated AUFs were then multiplied by a factor of ten to account for uncertainty in aquatic habitat patch fidelity.

5.1.2.1.6.2.4 Little brown bat

For little brown bats, AUFs of 0.25 are used for the NDA and SDA. In summer, females form maternity colonies, while locations of males are suspected to be solitary and scattered in a variety of roost types. While home range information is limited for little brown bats, a congeneric species, the gray bat, may travel as far as 12 km from roost caves to foraging sites (Sample et al. 1997).

Day and night roosts (e.g., buildings, hollows, trees, caves) are used by active bats in spring, summer, and fall. Little brown bats hibernate for approximately 6 months of the year (Davis and Hitchcock 1965), where hibernation roosts (hibernacula) in caves or abandoned mines are used.

Foraging is opportunistic and occurs in open habitat, frequently over bodies of water, whereas dense vegetation or flight obstructions are avoided. In New Hampshire, Anthony and Kunz (1977) observed bimodal foraging activity; the first feeding period was before midnight (2200-2400 h) while the second was before dawn (0330-0500 h). In contrast, Saunders and Barclay (1992) found activity was greatest within one hour of sunset. As such, foraging time is conservatively assumed to be 4 hours per Anthony and Kunz (1997).

Several abandoned mines are located within 12 km of the Facility, the closest being Burt Mine located approximately 0.5 km from the Facility. Due to relatively limited information on home range size, this AUF assumes foraging in aquatic exposure areas occurs 100% in the Facility for twelve hours per day for six months of the year, while little brown bats hibernate in caves or abandoned mines away from the Facility for six months of the year.

5.1.2.1.6.2.5 Muskrat

For the muskrat, an AUF of 1 is used for the NDA and SDA. Muskrats do not undergo torpor and are active year-round, with a reported home range of 0.27 ac from main dwellings or feeders (USEPA 1993b). Muskrats occupy a variety of freshwater habitats, including creeks, streams, lakes, marshes, and ponds. They prefer to excavate dens in banks or shores of waterways, whereas lodges are constructed in ponded areas.

As such, this AUF assumes that adult muskrats den and forage in flowing and non-flowing aquatic habitat and emergent and forested wetlands in aquatic exposure areas throughout the year.

5.1.2.1.6.2.6 Mink

For the mink, an AUF of 1 is used for the NDA and SDA. Mink do not undergo torpor and are active year-round (USEPA 1993b), with a reported home range of 1,903 and 19.3 ac for male and female adults, respectively. Mink occupy a variety of freshwater habitat, including rivers, streams, lakes, ditches, swamps, marshes, and backwater areas. Den sites are typically constructed in brushy or wooded cover adjacent to the water.

As such, these AUFs are based on adult female mink, given their reduced home range compared to adult males. It is assumed that adult female mink den and hunt in flowing and non-flowing aquatic habitat and emergent and forested wetlands in aquatic exposure areas throughout the year.

Section 6: Ecological Effects Assessment

The ecological effects assessment describes the potential effects associated with the exposure of identified COPECs to ecological receptors and reflects the type of AEs selected. The potential for effects is estimated by comparing COPEC concentrations in receptor species (daily dietary doses) to known effects concentrations from the literature. These benchmark values are concentrations of COPECs that are not expected to cause adverse effects to ecological receptors. ESBs were selected for evaluation of direct contact with lower-trophic-level organisms (i.e., invertebrates, fish, and plants) and wildlife TRVs were selected to evaluate exposure to upper-trophic-level organisms (i.e., birds and mammals, **Table 6-1**).

6.1 Toxicological Properties of COPECs

Brief toxicological profiles for major categories of COPECs (PAHs and metals) identified in Section 5 are presented below.

6.1.1 Polycyclic Aromatic Hydrocarbons

PAHs are composed of two or more aromatic or benzene rings. There is a large number (>10,000) of possible PAH structures that occur in the environment as complex mixtures (USEPA 2003c). PAHs show little tendency for bioconcentration despite their high lipid solubility (Pucknat 1981), likely because most PAHs are rapidly metabolized. PAHs evaluated at the Facility include the 16 priority pollutant PAHs identified by USEPA.

6.1.1.1 Invertebrates

PAHs deposited in sediments can affect benthic invertebrates differently, depending on the individual PAH and species of organisms. For instance, in sediment toxicity tests with the tubificid, *Limnodrilus hoffmeisteri*, Lotufo and Fleeger (1996) observed a median lethal phenanthrene concentration of 298 mg/kg. In the same study, pyrene concentrations up to 841 mg/kg were not acutely toxic. Decreases in tubificid reproduction were observed at lower levels. Bivalve mollusks tend to accumulate high PAH levels due to their inability to metabolize and excrete them (Eisler 1987a).

6.1.1.2 Fish

Most PAHs in aquatic environments are associated with particulate materials; only about 33% are present in dissolved form (Eisler 1987a). Fish have been shown to be capable of metabolizing PAHs better than other aquatic organisms (e.g., invertebrates) (Meador et al. 1995) Varanasi et al. (1985) as cited by the Agency for Toxic Substances and Disease Registry (ATSDR [1995]) ranked the extent of benzo(a)pyrene (BaP) metabolism by aquatic organisms as follows: fish > shrimp > amphipod > crustaceans > mussels. In addition, some fish species have been shown to avoid areas with high PAH concentrations (Rice 1973, Pastorok et al. 1994).

6.1.1.3 Wildlife

In general, PAHs show little tendency to biomagnify in food webs, despite their high lipid solubility, likely because most PAHs are rapidly metabolized. PAH exposure to mammalian and avian laboratory species is reported for both low- and high-molecular-weight PAHs (USEPA 2007b). Juvenile mice orally ingesting 2-methylnaphthalene at a dose of 110 mg/kg-body weight/day for 81 weeks exhibited reduced growth (Murata et al. 1997 in USEPA 2007b). Mice orally exposed

to BaP for 65 weeks (3.07 mg/kg-body weight/day) were found to have lower survival (Culp et al. 1998 in USEPA 2007b).

Sparse data are available on the effects of PAH ingestion to avian species. Patton and Dieter (1980) reported effects on liver function of mallards fed low-molecular-weight PAHs at the dose of 440 mg/kg-body weight/day for 7 months. European starlings (*Sturnus vulgaris*) gavaged with dimethylbenz(a)anthracene at a dose of 20 mg/kg-body weight/day for 5 days experienced reduced growth (Trust et al. 1994 in USEPA 2007b).

6.1.2 Metals

Metals enter the environment from natural processes and through anthropogenic sources. Chemical, physical, and biological factors influence the potential toxicity of metals. Generally, the bioavailable fraction of total metals concentrations can affect ecological receptors. Metals exhibit a range of binding affinities with both organic (e.g., carbon) and inorganic (e.g., other metals) substances, so the concentration of bioavailable fractions of metals varies. The total concentration of metals is generally not predictive of their bioavailability. Key factors that affect the partitioning and speciation, and thus the bioavailability, of metals include redox conditions, pH, hardness, organic carbon content, sulfide availability, and percent fines. These factors influence the sequestration, oxidation state, and species of dissolved ions present.

6.1.2.1 Arsenic

According to Eisler (1988a), most authorities agree on the following five points regarding ecological risk of arsenic in the environment: (1) arsenic is relatively common in air, water, soil, plants, and living tissues; (2) large quantities are released as a result of industrial and agricultural activities, posing risk to ecological receptors; (3) wildlife exposure may occur via air, water, and diet; (4) chronic exposure is associated with liver, kidney, and heart damage, hearing loss, altered brain activity, and impaired resistance to viral infections; and (5) arsenic is carcinogenic to mammals.

Elemental arsenic is rarely found in water, whereas predominant forms include pentavalent arsenic (As(V)) and arsenate compounds, trivalent arsenic (As(III)) and arsenite compounds, and arsenic sulfides. Inorganic species are favored during colder months, while reduced and methylated species are predominant in warmer months (Eisler 1988a). In waters with high dissolved oxygen, As(V) tends to exist as arsenic acid, dihydrogen arsenate, arsenious acid, and arsenate. In reducing environments (e.g., sediments), arsenate is reduced to arsenite species and methylated to methylarsonic acid (MAA) or dimethylarsinic acid (DMA). Though, even in reducing environments, reduction of As(V) to more soluble and toxic As(III) occurs slowly and is readily inhibited by the binding of As(V), while As(III) is rapidly oxidized to As(V) (Brannon 1987, Battelle & Exponent 2000).

6.1.2.1.1 Invertebrates

While As(III) is generally more toxic than As(V) to aquatic invertebrates (Eisler 1988a), experiments in marine and freshwater ecosystems and microcosms indicate that environmental exposure and effects of arsenic are significantly variable across invertebrate species, water/sediment chemistry, and arsenic speciation. For example, cladocerans and amphipods exhibited 50% immobilization after 96-h exposure at doses ranging from 0.63 to 4.3 mg As(III)/L (As(IV) equivalent effect at 7.4 mg/L in cladocerans), while 96 h As(III) LC50 in stoneflies (*Pteronarcys californica*) was 38 mg/L (Eisler 1988a).

6.1.2.1.2 Fish

While fish bioaccumulate arsenic, there is no evidence of biomagnification in aquatic food chains. Tissue concentrations are largely comprised of arsenobetaine, an organoarsenical compound with relatively lower toxicity than inorganic arsenic (Eisler 1988a). Marginal effects on rainbow trout (*Salmo gaidneri*) have been observed at 90 mg dietary As(V)/kg, while greater than or equal to 120 mg/kg of As(V) or As(III) resulted in malaise, food avoidance, and reduced metabolism. However, tolerance is species-specific, where impaired behavior in goldfish has been observed at 100 ug As(V)/L. Alternatively, 8 weeks of 1,600 mg/kg dietary exposure to methylated arsenicals did not elicit toxic effects in rainbow trout (Eisler 1988a).

6.1.2.1.3 Wildlife

Chronic inorganic arsenic exposure in mammals most notably includes adverse effects on the integumentary and nervous systems, and increased risk of skin, liver, bladder, and lung cancer (ATSDR 2007). Alternatively, scant mammalian toxicological information exists regarding organic arsenic compounds, though evidence suggests organic species are less toxic than inorganic species. Adverse effects involving respiratory, gastrointestinal, cardiovascular, and hematopoietic systems range from reversible to cancer and death, depending on the physical and chemical form of arsenic, route of administration, and dose (Eisler 1988a). Arsenic tolerance in birds varies among species, but adverse effects include involvement of neurological and reproductive systems and damage to gut blood vessels (Stanley et al. 1994; Whitworth et al. 1991; Camardese et al. 1990).

6.1.2.2 Copper

Copper is among the most toxic heavy metals to aquatic biota, while birds and mammals are relatively more resistant (Eisler 1997). Copper bioaccumulates and can cause irreversible harm to sensitive species at levels just above those considered essential for normal growth and metabolism. Alternatively, detoxifying mechanisms, particularly metallothionein induction, may allow for excess copper retention or excretion in vertebrates without observable effect. Inorganic copper exists in four oxidation states, of which cupric copper (Cu^{2+}) is the most toxic and readily bioavailable. Free cupric ions generally account for less than 1% of total dissolved copper in freshwater, where dissolved fractions are primarily complexed with carbonate, amino acids, and humic substances (Eisler 1997). In the presence of essential and non-essential trace elements, copper tends to be a disproportionate modifying factor driving synergistic or antagonistic interactions.

6.1.2.2.1 Invertebrates

In aquatic and terrestrial environments, adverse effects of copper to invertebrates may include reduced reproductive success, growth and development, motility, and survival. Gill damage and increased oxygen consumption may also occur in aquatic invertebrates, whereas reduced cocoon production and/or litter breakdown activity has been observed across genera of earthworms. In benthic invertebrate communities, reduced species richness, diversity, and abundance may occur where elevated tissue copper concentrations are observed (Eisler 1997). In general, aquatic and benthic invertebrate toxicity is greatest under conditions of low water hardness, starvation, elevated water temperatures, and among early developmental stages.

6.1.2.2.2 Fish

In fish, the external gill epithelial surface has a relatively low affinity for copper, allowing for greater penetration of intracellular compartments. Sublethal effects of copper may include adverse effects on blood chemistry, liver metabolism, respiration, reduced growth and appetite, inhibition of spawning, and depressed olfactory response (Eisler 1997). At high concentrations, copper may adversely affect osmoregulation, alter gill histopathology and function, and may cause necrosis of the liver parenchyma and/or irreversible damage to the olfactory organ.

6.1.2.2.3 Wildlife

In mammals, subchronic effects at oral doses ranging from 2 to 17 mg/kg-bw include reduced weight gain in rats and pigs and adverse effects on blood chemistry, blood pressure, sperm production and morphology, and squamous cell hyperplasia in rats (ATSDR 2024), while chronic effects include decreased hemoglobin. At oral doses ranging from 6.4 to 198 mg/kg-bw, subchronic mammalian effects may include hemolytic crisis, and/or morphological and histopathological changes in liver, kidney, and brain (ATSDR 2024; Eisler 1997). In birds, anemia, reduced weight gain, and adverse effects on gizzard histopathology were largely observed between 42 and 800 mg/kg-bw over two to 24 weeks (Eisler 1997).

6.1.2.3 Lead

Lead adversely affects survival, growth, reproduction, development, and metabolism of most species under controlled conditions, but its effects are substantially modified by numerous physical, chemical, and biological variables. In general, organic lead compounds are more toxic than inorganic lead compounds, food web biomagnification of lead is negligible, and younger, immature organisms are most susceptible to its adverse effects. Uptake of lead by terrestrial plants is limited by the low bioavailability of lead from soils. Lead concentrations in aquatic and terrestrial vertebrates tend to increase with increasing age of the organism, and to localize in hard tissues such as bone and teeth (Eisler 1988b).

6.1.2.3.1 Invertebrates

In general, the responses of aquatic invertebrate species to lead differ. In sensitive species the following conclusions can be made: dissolved waterborne lead is more toxic than total lead; organic lead compounds are more toxic than inorganic forms; and lead causes adverse effects on daphnid reproduction (Eisler 1988b).

6.1.2.3.2 Fish

Although lead is concentrated by biota from water, no significant biomagnification of lead occurs in aquatic food chains. Increasing waterborne concentrations of lead over 10 ug/l may cause increasingly severe long-term effects on fish and fisheries (Eisler 1988b). Lethal solutions of lead can cause a variety of adverse effects to fish including increased mucous formation, anemia, spinal curvature, degeneration of the caudal fin, muscular atrophy, and growth inhibition (Eisler 1988b).

6.1.2.3.3 Wildlife

In wildlife, lead can modify the function and structure of kidney, bone, the central nervous system, and the hematopoietic system. It can also produce adverse biochemical, histopathological, neuropsychological, fetotoxic, teratogenic, and reproductive effects.

Remedial goals at five Superfund Sites across the country range from 380 mg/kg to 605 mg/kg of lead in soil, based on robins, ground-feeding insectivores, or earthworm-feeding wildlife (Beyer et al. 2013). Field (bioavailability) data suggest that the remedial goals could be set even higher. For instance, Beyer et al. (2013) concluded a lack of effects to songbirds with lead soil concentrations less than 1,000 mg/kg in the southeast Missouri Lead Mining District. Hansen et al. (2011) showed no effects to robins with lead soil concentrations of up to 1300 mg/kg in Idaho's Coeur d'Alene River Basin. In addition, data from the Dutchman Riparian Lands at the Anaconda Superfund Site indicate no adverse effects to robins with lead in soils below 2,000 mg/kg (Texas Tech 2002).

6.1.2.4 Mercury

According to Eisler (1987b), most authorities agree on the following six points regarding mercury in the environment (1) mercury and its compounds have no known biological function, and the presence of the metal in the cells of living organisms is undesirable and potentially hazardous; (2) forms of mercury with relatively low toxicity (e.g., inorganic compounds) can be transformed into forms of mercury with high toxicity (i.e. organomercury compounds, such as methylmercury) through biological and other processes; (3) mercury can be bioconcentrated in organisms and biomagnified through food chains; (4) mercury is a mutagen, teratogen, and carcinogen; (5) some species of fish and wildlife contain high concentrations of mercury that are not attributable to human activities; (6) the difference between tolerable natural background levels of mercury and harmful effects in the environment is small.

6.1.2.4.1 Invertebrates

Mercury at comparatively low concentrations adversely affects the reproduction, growth, behavior, metabolism, blood chemistry, osmoregulation, and oxygen exchange of marine and freshwater organisms. In general, the accumulation of mercury by aquatic biota is rapid, and depuration is slow. It is emphasized that organomercury compounds, especially methylmercury, were significantly more effective than inorganic mercury compounds in producing adverse effects and accumulations.

For sensitive marine invertebrates such as hydroids, protozoans, and mysid shrimp, reproduction was inhibited at concentrations between 1.1 and 2.5 ug Hg^{2+}/l; this range was 5 to 71 ug/l for more resistant species of marine invertebrates (Eisler 1987b).

6.1.2.4.2 Fish

In general, the accumulation of mercury in fish is enhanced at elevated water temperatures, reduced water salinity or hardness, reduced water pH, increased age of the fish, and reduced organic matter content of the medium; in the presence of zinc, cadmium, or selenium in solution; after increased duration of exposure; and in the presence of increased nominal concentrations of protein-bound mercury. Uptake patterns were significantly modified by sex, sexual condition, prior history of exposure to mercury salts, the presence of complexing and chelating agents in solution, dietary composition, feeding niche, tissue specificity, and metabolism; however, trends were not consistent between species and it is difficult to generalize (Eisler 1987b).

6.1.2.4.3 Wildlife

For the protection of sensitive species of birds that regularly consume fish and other aquatic organisms, total mercury concentrations in the prey items should not exceed 100 ug/kg fresh weight. For some birds, adverse effects, predominantly on reproduction, have been associated

with total mercury concentrations of (in fresh weight) of 5,000 ug/kg in feather, 900 ug/kg in egg; and with daily intakes of 640 ug/kg body weight (Eisler 1987b).

The significance of elevated mercury levels in tissues of fish and wildlife is not fully understood; some species of marine pinnipeds, for example, normally contain high concentrations of mercury in various tissues without apparent adverse effects. Mercury concentrations in sensitive mammals in excess of 1,100 ug/kg fresh weight of tissue (liver, kidney, blood, brain, hair) or when daily intakes reach 250 ug/kg body weight can cause adverse effects (Eisler 1987b).

6.1.2.5 Zinc

According to Eisler (1993), most authorities agree on the following points regarding ecological risk of zinc in the environment: (1) elevated concentrations (i.e., greater than 2 g/kg fresh weight [FW]) are normally encountered in some species of oysters, scallops, barnacles, red and brown algae, and terrestrial arthropods; (2) tissue concentrations are usually less than 700 mg/kg dw in fish, less than 210 mg/kg dw in birds, and less than 210 mg/kg dw in mammals; (3) concentrations are higher in animals and plants collected near zinc-contaminated sites than in the same species collected from more distant sites; (4) zinc content in tissue is not proportionate to that of the organism's immediate surroundings; (5) for individual species, zinc concentration varies with age, sex, season, tissue or organ, and other variables; and (6) many species contain zinc loadings far in excess of immediate needs, suggesting active zinc regulation.

Zinc predominantly occurs in the environment as Zn(II), though it is frequently complexed with organic and inorganic ligands. Zinc bioaccumulates in terrestrial and aquatic food chains (but does not biomagnify) and biota appear to represent a relatively minor sink compared to sediment/soil (ATSDR 2005). Though, ecotoxicity in sediment and soil is complex and driven largely by pH, oxidation-reduction potential, organic carbon content, and the presence of acid volatile sulfides, co-occurring metals, and organic ligands.

As with other metals, metallothionein and metallothionein-like protein (MTLP) induction acts as a detoxifying mechanism for zinc in vertebrate and invertebrate species. Additionally, dietary zinc can mediate excess copper toxicity via induction of metallothionein synthesis, whereby metallothionein exhibits a greater binding affinity to copper than zinc, decreasing absorption into plasma and systemic uptake (ATSDR 2005).

6.1.2.5.1 Invertebrates

Reduced earthworm survival and inhibited woodlouse reproduction were observed at soil concentrations above 470 and 1,600 mg/kg, respectively, while reduced growth in slugs occurred above 300 mg/kg dietary intake (Eisler 1993). Representative soil invertebrates have also shown reduced growth at 300-1,000 mg/kg of dietary zinc and reduced survival at soil concentrations of 470-6,400 mg/kg. Acute LC50 (96 h) values have been observed between 32 and 40,930 µg/L for freshwater invertebrates but the most sensitive aquatic species were adversely affected between 10 and 25 µg/L.

6.1.2.5.2 Fish

Excess zinc can disrupt normal metabolism of fish gills, and acute toxicosis in fish may include osmoregulatory failure, acidosis and low oxygen tensions in arterial blood, inhibited immune response, and disrupted gas exchange at the gill surface and internal tissue sites (Eisler 1993).

Zinc is teratogenic to fish embryos, and gill epithelia of fish are the primary target of zinc toxicity, with high concentrations in the water column causing destruction of gill epithelium and tissue hypoxia. Though, acutely toxic doses are significantly variable in freshwater teleosts (96 h LC50 range: 66 to 40,900 µg/L; Eisler 1993).

6.1.2.5.3 Wildlife

In mammals, chronic exposure to excess dietary zinc may result in adverse effects to the gastrointestinal system, pancreas, and bone, and decreased copper absorption leading to anemia (ATSDR 2005). The pancreas and bone are the primary targets of zinc toxicity in mammals and birds. Zinc preferentially accumulates in bone, and excess zinc may cause stimulation of bone resorption and inhibition of bone formation in chicks, osteomalacia. Further, pancreatic abnormalities have been observed in birds and mammals following oral exposure to zinc. Zinc is not considered a mammalian or avian carcinogen by dermal, inhalation, or oral administration. Zinc poisoning in wildlife typically occurs in birds when the liver or kidney residues exceed 2,100 mg/kg dw, and in mammals when concentrations exceed 274, 465, and 752 mg/kg dw in kidney, liver, and pancreas, respectively (Eisler 1993).

6.2 Potential Direct Effects

Direct exposure risks to lower-trophic-level receptors (i.e., plants, terrestrial and aquatic invertebrates, and fish) are evaluated via a comparison of soil, sediment, or surface water EPCs to available ESBs used to represent threshold values below which adverse effects are unlikely.

ESB sources include:

- Plants and terrestrial invertebrates:
  - NJDEP ESC table (NJDEP 2009)
  - USEPA (2007a) EcoSSLs
  - USEPA's Ecotox Database
  - Oak Ridge National Laboratory (e.g., Efroymson et al.1997a, 1997b)
  - Published peer-reviewed journal articles (e.g., Sverdrup et al. 2003; Talmage et al. 1999)
- Benthic invertebrates:
  - NJDEP ESC table (NJDEP 2009)
  - Mid-Atlantic (Region 3 Biological Technical Assistance Group [BTAG]) Freshwater Sediment Screening Values (USEPA 2006)
  - Published peer-reviewed journal articles (e.g., Persaud et al. 1993)
  - USEPA (2003a) Region 5 ESLs
  - Conder et al. (2015)
- Fish:
  - NJDEP ESC table (NJDEP 2009)

- Mid-Atlantic (Region 3 BTAG) Freshwater Screening Values (USEPA 2006)
- National Recommended Water Quality Criteria (USEPA 2009)

Section 7 compares soil, sediment, and surface water EPCs to ESBs to characterize potential risk from direct contact exposures.

6.3 Potential Wildlife Effects

USEPA (2007a) defines a TRV as a dose (based on laboratory toxicological investigations) above which a particular ecologically relevant effect may be expected to occur in an organism following chronic dietary exposure, and below which it is reasonably expected that such effects will not occur. Rather than deriving one point estimate associated with specific biological effects, both high and low TRVs are identified for each COPEC to bracket a threshold effect level.

The low TRV is a conservative value consistent with a chronic no observed adverse effects level (NOAEL). It represents a conservative dose level at or below which adverse effects are unlikely to occur. Conversely, the high TRV is a less conservative estimator of potential adverse effects, representing a dose level at which adverse effects may occur, and is consistent with a chronic lowest observed adverse effects level (LOAEL). As recommended by USEPA (1997a), in the absence of either a NOAEL or LOAEL, the missing value was obtained by extrapolating from the existing value by a factor of 10.

The following literature sources were reviewed for the selection of TRVs for upper-trophic-level wildlife (i.e., birds and mammals):

- USEPA EcoSSLs (USEPA 2003b, 2007a, 2007b)
- Toxicological studies cited in Sample et al. (1996)
- California Department of Toxic Substances Control (DTSC) BTAG TRVs for Birds and Mammals (DTSC 2002)
- Wildlife Toxicity Assessment Program at the U.S. Army Center for Health Promotion and Preventative Medicine (USACHPPM: 2001a, 2001b, 2001c, 2007, 2012)
- Wildlife Toxicity Assessments for Chemicals of Military Concern. (U.S. Army Institute of Public Health [AIPH] 2015).

When reviewing the toxicological literature and selecting the most appropriate study for TRV development, several factors were considered:

- Taxonomic relationship between the test animal and the receptor species.
- Use of laboratory animals or domesticated species, with preference for wildlife species.
- Toxicological studies where the chemical was administered through diet are preferred over studies using other dosing methods, such as oral gavage or intraperitoneal injection.
- Ecological relevance of the study endpoints. Studies with toxicity endpoints such as reproduction, growth, behavior, and developmental endpoints were targeted. Sensitive endpoints such as reproductive or developmental toxicity were preferentially selected because they are closely related to the selected AEs.

- Long-term studies representing chronic exposure were preferentially selected over short-term, acute studies.

Mammalian and avian TRVs are presented in **Table 6-1**. In general, these TRVs are consistent with those used in the 2016 EE/ERA and discussed in the ERAWP.

Notable exceptions are discussed in the following section.

6.3.1 Lead

In the 2016 EE/ERA, TRVs for lead were obtained from the EcoSSL documents (USEPA 2005) which were conservatively developed. For instance, the form of metal used to dose animals in a laboratory study is frequently the most toxic and most bioavailable form to ensure uptake by the animal. While the form of lead in Facility soils is often metallic lead, many of the toxicity studies are based upon toxic lead forms such as lead acetate or lead nitrate (USEPA 2005). This adds additional conservatism into the evaluation.

Furthermore, avian toxicity data used in the development of the TRVs include reproduction data for chickens, a domestic bird species with higher rates of reproduction than wild birds. In fact, TRVs recommended by USEPA (2005) for lead are based exclusively on reproduction in chickens. For this assessment, TRVs based on wild bird data, NOAEL-based TRVs for reproduction range from 0.194 to 125 mg/kg bw/day; LOAEL-based TRVs for reproduction range from 0.11 to 377 mg/kg bw/day, with a geometric mean of 11.4 mg/kg bw/day, were selected.

Sample et al. (1996) reports a similar LOAEL (11.3 mg/kg bw/day) based on a study of Japanese quail (from Edens et al. 1976). This LOAEL was also used by Kaufman et al. (2007) to evaluate the bioaccessibilty of lead to birds and mammals. Edens et al. (1976) reports a NOAEL of 1.13 mg/kg bw/day for lead. As such, 1.13 and 11.3 mg/kg bw/day will serve as the avian TRVs for lead.

For mammals, conservative TRVs used in the 2016 EE/ERA are modified from 4.7 to 8 mg/kg bw/day for the NOAEL and from 8.9 to 80 mg/kg bw/day for the LOAEL. These TRVs are reported in Sample et al. (1996) and are based on a study by Azar et al. (1973) using laboratory rats.

These updated lead TRVs are presented in **Table 6-1**.

Section 7: Ecological Risk Characterization

Risk characterization evaluates potential ecological risk to receptors. For lower-trophic-level terrestrial and aquatic receptors (i.e., terrestrial plants and invertebrates, aquatic invertebrates and fish) potential risks were characterized by comparing soil, sediment, or surface water EPCs to ESBs, which results in an HQ.

For benthic invertebrate communities, EPCs were compared to LEL and SEL criteria considered protective of benthic organisms. These LEL- and SEL-based HQs (HQ_{LELs} and HQ_{SELs}, respectively) were calculated to provide a bounding estimate of potential risk. Where HQ_{LELs} were greater than 1, supplemental LOEs were evaluated (as detailed in Section 5.1.1.2) and incorporated in risk characterization.

For upper-trophic-level avian and mammalian species, resulting dietary doses from the food web models were compared to TRVs to derive the HQs. NOAEL-based HQs (HQ_{NOAEL}) and LOAEL-based HQs (HQ_{LOAEL}) were calculated for both the low and high TRVs, respectively. In general, HQ_{NOAEL} less than one indicate that there are no potential ecological risks and HQ_{LOAEL} less than one suggest that adverse effects are unlikely. With respect to HQ_{LOAEL} greater than 1, USEPA (1994) recommends that HQs be interpreted relative to the assumptions on which the assessment is based. In other words, more conservative exposure and effects assumptions result in a broader range of tolerable HQs. The following sections present both the HQ_{NOAEL} and HQ_{LOAEL} to provide bounding estimates of potential risk to upper-trophic-level receptors.

7.1 Terrestrial Receptors

The following section summarizes HQs for terrestrial receptors at the Facility. **Tables 7-1 through 7-8** present the results of the terrestrial receptor evaluation. **Table 7-9** summarizes the results presented in **Tables 7-1 through 7-8**.

As detailed in Section 5.1.1.1.1.1 (Lead Bioavailability), results of SEP analysis indicate that 24 to 56% of lead in soil is weakly bound and potentially bioavailable. The following summary tables incorporate HQs assuming 24, 56, and 100% bioavailability of lead in soil.

7.1.1 Soil Invertebrates

Table 7-1 presents HQs based on maximum detected constituent concentrations and 95UCL EPCs estimating potential risks to soil invertebrates. The following table summarizes COPECs with HQs greater than one (based on the 95UCL).

COPEC	Soil Invertebrate HQ (95UCL)
Copper	2
Manganese	8
Vanadium	2
Zinc	2

7.1.2 Plants

Table 7-2 presents HQs based on maximum detected constituent concentrations and 95UCL EPCs estimating potential risks to terrestrial plants. The following table summarizes COPECs with HQs greater than one (based on the 95UCL).

COPEC	Terrestrial Plant HQ (95UCL)
Chromium	24
Copper	2
Lead (24 / 56 / 100)[a]	≤1 / 3 / 5
Manganese	3
Mercury	32
Selenium	6
Vanadium	17

[a]Lead HQs assume 24, 56, and 100% bioavailability of lead in soil

7.1.3 Wildlife

Potential ecological risk was evaluated for three avian receptors (**Tables 7-3, 7-4, and 7-5**) and three mammalian receptors (**Tables 7-6, 7-7, and 7-8**). **Table 7-9** summarizes the terrestrial receptor HQs.

7.1.3.1 Birds

The evaluation of potential ecological risks for American robin, northern bobwhite, and red-tailed hawk indicates the following:

- Two COPEC HQ_{NOAELs} and one HQ_{LOAEL} exceeds 1 for American robin.
- COPEC HQ_{NOAELs} and HQ_{LOAELs} are less than or equal to 1 for northern bobwhite.
- COPEC HQ_{NOAELs} and HQ_{LOAELs} are less than or equal to 1 for red-tailed hawk.

The following table summarizes COPECs with HQs greater than 1.

COPEC	American Robin	
	HQ_{NOAEL}	HQ_{LOAEL}
Copper	**2**	≤1
Lead (24 / 56 / 100)[a]	**3 / 5 / 9**	≤1 **/ 3 / 5**

[a]Lead HQs assume 24, 56, and 100% bioavailability of lead in soil

7.1.3.2 Mammals

The evaluation of potential ecological risks for short-tailed shrew, white-tailed deer, and red fox indicates the following:

- One COPEC HQ_{NOAEL} exceeds 1 for short-tailed shrew. HQ_{LOAEL} is less than or equal to 1.
- COPEC HQ_{NOAELs} and HQ_{LOAELs} are less than or equal to 1 for white-tailed deer.
- COPEC HQ_{NOAELs} and HQ_{LOAELs} are less than or equal to 1 for red fox.

The following table summarizes COPECs with HQs greater than 1.

COPEC	Short-Tailed Shrew	
	HQ_{NOAEL}	HQ_{LOAEL}
Lead (24 / 56 / 100)[a]	≤1 / ≤1 / **2**	≤1

[a]Lead HQs assume 24, 56, and 100% bioavailability of lead in soil

7.2 Aquatic Receptors

Sections 7.2.1-2 presents HQs for aquatic receptors in subdrainage exposure areas within the NDA and SDA. HQs were calculated for benthic invertebrates, aquatic life (fish and aquatic invertebrates), tree swallow, great blue heron, mallard duck, little brown bat, mink, and muskrat. **Tables 7-10 through 7-27** present COPEC HQs for each receptor. **Table 7-28** summarizes HQs for aquatic wildlife receptors.

7.2.1 Northern Drainage Area

The NDA encompasses several aquatic habitats, including several ponds and tributaries, across five distinct subdrainage areas. Results of the evaluation for these subdrainage areas are presented in **Tables 7-10 through 7-18**.

7.2.1.1 Benthic Invertebrates

Multiple LOEs were considered during refined risk characterization of benthic invertebrates in NDA subdrainage areas. Benthic invertebrate EPCs were initially compared to LELs and SELs considered protective of benthic invertebrates (**Table 7-10**).

NDA subdrainage areas COPEC HQ_{LELs} and HQ_{SELs} greater than 1 are summarized in the following table.

NDA Subdrainage Areas – Benthic Invertebrate Risk Evaluation										
COPEC	Duck Pond		Eastern Tributary		Northeast Ponds		Unnamed Ponds		Western Tributary	
	HQ_{LEL}	HQ_{SEL}	HQ_{LEL}	HQ_{SEL}	HQ_{LEL}	HQ_{SEL}	HQ_{LEL}	HQ_{SEL}	HQ_{LEL}	HQ_{SEL}
Metals										
Arsenic	**2**	≤1	**2**	≤1	≤1	≤1	**4**	≤1	≤1	≤1
Cadmium	**2**	≤1	≤1	≤1	≤1	≤1	**2**	≤1	**2**	≤1
Copper	**4**	≤1	**12**	≤1	**3**	≤1	**5**	≤1	**5**	≤1
Lead	**6**	≤1	**8**	≤1	**2**	≤1	**9**	≤1	**12**	≤1
Mercury	≤1	≤1	≤1	≤1	≤1	≤1	**8**	≤1	**5**	≤1
Silver	≤1	--	≤1	--	**5**	--	≤1	--	≤1	--
Zinc	**3**	≤1	**2**	≤1	**2**	≤1	**6**	≤1	**3**	≤1
SVOCs										
PAHs[a]	(≤1-**2**)	≤1	≤1	≤1	≤1	≤1	(≤1-**7**)	≤1	≤1	≤1

Notes: [a]The PAH ecological screening benchmark toxic unit (ESBTU) threshold of 1 (unitless) was calculated using a 34-PAH dataset, where available (see Section 5.1.1.1.2.2); otherwise, a ESBTU benchmark of 8.83 (unitless) was used, representing a 13-PAH benchmark with 95% certainty factor and equating to a 34-PAH benchmark of 1.
HQ – hazard quotient
LEL – lowest effect level
SEL – severe effect level
-- = no SEL available

In subdrainage areas where the comparison of COPEC EPCs to SELs and LELs indicated potential unacceptable risk to benthic invertebrates (i.e., HQ_{LEL} greater than 1), additional LOEs were evaluated. Supplemental evaluations identified acceptable risk within four subdrainage areas. In Unnamed Ponds, potentially unacceptable risk was remained for arsenic and mercury in sediment. As such, additional investigation of Unnamed Ponds for these sediment COPECs is recommended.

The table below summarizes the results of these supplemental evaluations for each NDA subdrainage area.

The table below summarizes the results of supplemental LOEs for each NDA subdrainage area.

NDA Subdrainage Areas - Benthic Invertebrate Risk Evaluation						
Risk Evaluation Method	**Notes**	**Unnamed Ponds**	**Duck Pond**	**Eastern Tributary**	**Western Tributary**	**Northeast Ponds**
ESC Screen	b	+	+	+	+	+
Background Arsenic Threshold	d	+	-	NA	NA	NA
Mercury Study Comparison	d	+	-	NA	-	NA
Total and Dissolved MeHg	c	+	NA	NA	NA	NA
EqP PAH Analysis	c,d	-	-	NA	NA	-
AVS/SEM and Surrogate TOC%	a,c,d	-	-	-	-	-
Biological Community Indices*	c	+	NA	NA	NA	R
Risk Drivers	-	As, Hg	None	None	None	None
Additional Assessment? (Y/N)	**-**	**Y**	**N**	**N**	**N**	**N**

Notes: + = potential unacceptable risk, retained as a COPEC; - = acceptable risk. not retained as a COPEC; NA = not analyzed; R = reference location; As = arsenic; Hg = mercury; MeHg = methylmercury
[a]The AVS/SEM and Surrogate TOC% evaluation method represents a LOE for divalent metals including cadmium, copper, lead, nickel, and zinc.
[b]Evaluated in Appendix F of KJ (2016) (**Attachment 1**)
[c]Evaluated during ERASSM implementation
[d]Evaluated in Updated SSRP (**Attachment 4**)

* This evaluation method is weighted more heavily, as the data are from site specific sources

7.2.1.2 Aquatic Plants

Summarizes COPECs with HQs greater than one based on the 95UCL, where applicable. Where the 95UCL could not be calculated, the HQ is based on the maximum concentration [HQ_{max}].

NDA Subdrainage Areas – Aquatic Plant Risk Evaluation					
COPEC	Duck Pond	Eastern Tributary	Northeast Ponds	Unnamed Pond	Western Tributary
	Aquatic Plant HQ_{95UCL}				
Metals					
Arsenic	≤1	≤1[a]	≤1	**4**	≤1
Cadmium	≤1	≤1	≤1	≤1	**2**
Copper	≤1	**3[a]**	≤1	≤1	≤1
Lead	**2**	**2[a]**	≤1	**2**	**3**
Mercury	≤1	≤1	≤1	≤1	**3**
Silver	≤1	≤1	≤1[a]	**6**	≤1
Zinc	**2**	≤1	**2**	**5**	**2**

Notes: [a]HQ_{max}

7.2.1.3 Fish and Aquatic Invertebrates

Table 7-12 presents HQs estimating potential risks to fish and aquatic invertebrates in NDA subdrainage areas. HQ calculations estimate potential risks to fish and aquatic invertebrates. The following table summarizes COPECs with HQs greater than one (based on the 95UCL).

NDA Subdrainage Areas Fish and Aquatic Invertebrate Risk Evaluation		
COPEC	Western Tributary	
Fish and Aquatic Invertebrate $HQ_{95UCL/max}$		
Metals		
Copper, dissolved	**3**	a
Lead, dissolved	**147**	a
Zinc, dissolved	**2**	a

Notes: [a]HQ_{95UCL}; [b]HQmax;
-- = not a COPEC for this subdrainage area

7.2.1.4 Birds

The evaluation of potential ecological risks for tree swallow, great blue heron, and mallard duck using aquatic habitats in NDA subdrainage areas, as presented in **Tables 7-13, 7-14, and 7-15**, indicates the following:

- COPEC HQ_{NOAELs} are less than or equal to 1 for great blue heron.
- COPEC HQ_{NOAELs} are less than or equal to 1 for mallard duck.

- COPEC HQ_{NOAELs} are less than or equal to 1 for tree swallow.

7.2.1.5 Mammals

The evaluation of potential ecological risks for little brown bat, mink, and muskrat using aquatic habitats in NDA subdrainage areas, as presented in **Tables 7-16, 7-17, and 7-18**, indicates the following:

- Three COPEC HQ_{NOAELs} and two COPEC HQ_{LOAELs} exceed 1 for little brown bat.
- Three COPEC HQ_{NOAELs} exceed 1 for mink. HQ_{LOAELs} are less than or equal to 1.
- COPEC HQ_{NOAELs} are less than or equal to 1 for muskrat.

The following table summarizes COPECs with HQs greater than 1.

NDA Subdrainage Areas – Mammal Risk Evaluation				
COPEC	Little Brown Bat		Mink	
	HQ_{NOAEL}	HQ_{LOAEL}	HQ_{NOAEL}	HQ_{LOAEL}
Duck Pond				
Nitroglycerin	≤1	≤1	**5**	≤1

Lead	**5**	**3**	≤1	≤1
Unnamed Ponds				
Arsenic	**2**	≤1	≤1	≤1

7.2.2 Southern Drainage Area

The SDA drains the majority of the former operational area of the Facility. **Tables 7-19 through 7-27** present results of the evaluation for SDA subdrainage areas.

7.2.2.1 Benthic Invertebrates

Multiple LOEs were considered during refined risk characterization of benthic invertebrates in SDA subdrainage areas. Benthic invertebrate EPCs were initially compared to LELs and SELs considered protective of benthic invertebrates (**Table 7-19**).

SDA subdrainage area COPEC HQ_{LELs} and HQ_{SELs} greater than 1 are summarized in the following table.

SDA Subdrainage Area Sediment COPECs								
COPEC	**Central Drainage Basin**		**Development Area Stream**		**Maintenance - Dynamite Area - East**		**Maintenance – Dynamite Area - West**

Notes: [a]The PAH ecological screening benchmark toxic unit (ESBTU) threshold of 1 (unitless) was calculated using a 34-PAH dataset, where available (see Section 4.2.1.1.1); otherwise, a ESBTU benchmark of 8.83 (unitless) was used, representing a 13-PAH benchmark with 95% certainty factor and equating to a 34-PAH benchmark of 1.
HQ – hazard quotient
LEL – lowest effect level
SEL – severe effect level
-- = not a COPEC for this subdrainage area

In SDA subdrainage areas where the EPC comparison to SEL and LELs indicated potentially unacceptable risk to benthic invertebrates (i.e., HQ_{LEL} greater than 1), additional LOEs were evaluated.

Supplemental evaluations identified acceptable risk within seven SDA subdrainage areas. Alternatively, risk characterization across multiple LOEs in the Maintenance NG Area identified potential unacceptable risk to benthic invertebrate communities from sediment COPECs including arsenic, mercury, and silver. Additional investigation in the Maintenance NG Area for these COPECs is recommended.

The following table summarizes the results of the supplemental evaluations for each SDA subdrainage area.

7.2.2.2 Aquatic Plants

Table 7-20 presents HQs estimating potential risks to aquatic plants in SDA subdrainage areas. Metals and PAHs are the primary risk drivers for aquatic plants (i.e., have HQs greater than 1). The following table summarizes COPECs with HQs greater than one based on the 95UCL, where applicable. Where the 95UCL could not be calculated, the HQ_{max} is used.

SDA Subdrainage Areas – Aquatic Plant Risk Evaluation (HQ_{95UCL})

7.2.2.3 Fish and Aquatic Invertebrates

Table 7-21 summarizes potential risks to fish and aquatic invertebrates in SDA subdrainage areas.

No COPECs were retained from the initial ESC screen for the SDA subdrainage areas.

7.2.2.4 Birds

The evaluation of potential ecological risks for tree swallow, great blue heron, and mallard duck using aquatic habitats in SDA subdrainage areas, as presented in **Tables 7-22, 7-23, and 7-24**, indicates the following:

- COPEC HQ_{NOAELs} are less than or equal to 1 for mallard duck.
- COPEC HQ_{NOAELs} are less than or equal to 1 for mallard duck.
- COPEC HQ_{NOAELs} are less than or equal to 1 for tree swallow.

7.2.2.5 Mammals

The evaluation of potential ecological risks for little brown bat, mink, and muskrat in eight subdrainage areas in SDA subdrainage areas, as presented in **Tables 7-25, 7-26, and 7-27**, indicates the following:

- COPEC HQ_{NOAELs} are less than or equal to 1 for little brown bat.
- Three COPEC HQ_{NOAELs} and one COPEC HQ_{LOAEL} exceed 1 for mink.
- Two COPEC HQ_{NOAELs} and two COPEC HQ_{LOAEL} exceed 1 muskrat.

The following table summarizes COPECs with HQs greater than 1 in SDA subdrainage areas.

SDA Subdrainage Areas				
COPEC	Mink		Muskrat	
	HQ_{NOAEL}	HQ_{LOAEL}	HQ_{NOAEL}	HQ_{LOAEL}

7.3 PCDD/F Risk Characterization

The 2016 EE/ERA **(Attachment 1)** presents an ERA specific to PCDD/F in soil in former burning areas of the Facility. General site characterization sampling in the SI/RI did not include analysis for PCDD/F. Focused PCDD/F sampling was conducted in areas of the site that supported historical burning activities and in response to a request by NJDEP. PCDD/F data were evaluated separately given the differences in size and spatial coverage of the datasets (i.e., Facility-wide [more than 1,000 acres] versus four discrete former burning areas totaling less than 10 acres). Food web modeling was conducted for each of the terrestrial receptors evaluated in this ERA using congener-specific 95UCLs for PCDD/F and a toxicity equivalency quotient (TEQ)-based

approach (Van den Berg et al. 1998, 2006). Species-specific exposure factors used in the food web model for PCDD/F remain consistent with those in the overall ERA.

As summarized in the table below, food web models for PCDD/F in soil resulted in HQs less than 1 for each ecological receptor evaluated. These results indicate that potential ecological risk attributable to PCDD/F in soil in former burning areas of the Facility is unlikely.

PCDD/F – Former Burning Area Soil	
Receptors	**HQs**
American robin	≤1
Red-tailed hawk	≤1
Bobwhite quail	≤1
Short-tailed shrew	≤1
Red fox	≤1
White-tailed deer	≤1

7.4 Discussion

The risk characterization compares COPEC concentrations in potential receptors to conservative benchmark values identified in Section 6. To characterize potential ecological risk to populations using the exposure areas, consideration of benchmark values below which significant effects are not expected (i.e., LOAEL-based TRVs) to occur is appropriate.

7.4.1 Terrestrial Exposure Area

Potential risks to terrestrial receptors were evaluated Facility-wide. Soil COPECs, including four metals (lead, chromium, vanadium, and copper), present the highest potential for risk to terrestrial receptors via both direct exposure and food-web transfer.

Metals are commonly associated with historical fill materials (e.g., fly ash, bottom ash, slag), which were byproducts of the local iron mining and processing industry and imported to the Facility as fill to support Facility development in the early 1900s.

Overall, potential risks to terrestrial receptor populations related to COPECs other than lead are low.

Section 5.1.1.1.2. presents an initial evaluation and framework for refining risks attributable to individual sample locations or clusters of sample locations where COPEC concentrations may result in localized risk (e.g., hotspots).

Similarly, Section 3.2.1.3.1. presents an approach to assessing risk to sensitive populations (e.g., bog turtle) in wetland areas.

7.4.2 Aquatic Exposure Areas

Aquatic exposure pathways were evaluated across 13 subdrainage areas.

Due to its earlier development in the Facility's history, the majority of historic fill imported to the Facility was used to raise the ground surface elevation and support development in the SDA, and once developed, this area housed the largest concentration of historical operations and facility

support services (e.g., Maintenance Area, powerhouse). These historical differences are evident in aquatic HQs from these exposure areas, as discussed below.

7.4.2.1 Northern Drainage Area

Four constituents (i.e., arsenic, copper, and lead) emerge as potential risk drivers in NDA subdrainage areas. Copper and lead concentrations yielded HQs greater than 1 for direct contact exposure scenarios (i.e., fish and aquatic plants and invertebrates) as well as aquatic food web modeling for upper-trophic-level mammals (i.e., little brown bat and mink). Arsenic also represents a potential risk to lower- and upper-level aquatic receptors, though elevated risk estimates are confined to the Unnamed Ponds (i.e., aquatic plants, benthic invertebrates, and little brown bat) and the Maintenance - NG Area (i.e., benthic invertebrates) and likely attributable to historical fill.

Potentially elevated risk from six COPECs (i.e., barium, cadmium, mercury, manganese, silver, and zinc), while also exceeding aquatic risk thresholds across multiple subdrainage areas, is restricted to lower-trophic-level receptors (i.e., aquatic plants and benthic invertebrates). Further, nitroglycerin presents a potential risk to piscivorous mammals (i.e., mink), though elevated risk estimates are limited to Duck Pond. Nitroglycerin is assumed to be 100% bioavailable to aquatic receptors in this ERA. In reality, nitroglycerin occurs at the Facility as a component of solid smokeless powder grains and thus is bound in an insoluble matrix with likely limited bioavailability.

Overall, Unnamed Ponds and the Eastern and Western Tributaries emerge as NDA subdrainage areas with the highest potential risk to aquatic receptors. Alternatively, potential risk to birds in each evaluated feeding guild is low in NDA subdrainage areas.

7.4.2.2 Southern Drainage Area

Lead, fluoranthene, pyrene emerge as having the greatest potential for ecological risk in the SDA. Fluoranthene and pyrene are potential risk drivers to herbivorous mammals (i.e., muskrat) and piscivorous mammals (i.e., mink), while lead exceeds aquatic risk thresholds for fish, aquatic plants and invertebrates, and piscivorous mammals across several SDA subdrainage areas.

Potential risk from mercury, frequently co-located with lead, is limited to sediment direct contact in lower-trophic-level receptors (i.e., aquatic plants and benthic invertebrate communities). While bioavailability of mercury to lower-trophic-level receptors via microbial methylation is uncertain, multiple LOEs indicate potential risk to benthic invertebrates from co-located COPECs is limited to the Central Drainage Basin, Maintenance – Dynamite Area – West, and Maintenance – NG Area. While chromium exceeded HQs for lower-trophic-level receptors (i.e., benthic invertebrates and aquatic plants) in the Maintenance - Dynamite Area - East, speciation analysis indicates that sediment conditions favor the less mobile and bioavailable Cr(III).

Arsenic, copper, silver and zinc also present potential risk to lower-trophic level receptors (i.e., fish, aquatic plants and invertebrates, and benthic invertebrates) though elevated risk estimates are more limited in distribution across SDA subdrainage areas. Apart from fluoranthene and pyrene, potential risk is limited to aquatic plants, where the Central Drainage Basin, Maintenance – Dynamite Area – East and West, and Miscellaneous Offsite Streams - Lower represent the highest potential risk areas and most frequent HQ_{95UCL} exceedances for 12 PAH congeners.

The emergence of lead to present potential risk in multiple media and exposure scenarios is not unexpected given the presence of lead in commerce, historical fill, and use of lead in historical Facility operations. Lead possesses non-conductive/non-sparking properties and several buildings were partially lined with lead, as were material conveyances (i.e., pipes, culverts,

vessels). Lead used onsite existed primarily in the inorganic form, which is not readily bioavailable and not expected to bioaccumulate.

Vegetated wetland features make up the majority of aquatic habitat in the SDA with intermittent ditches and other drainage features draining wetlands to the large southern wetland complex. Sediment in these wetland habitats is rich in organics (SDA total organic carbon average of 5.8 percent, with a maximum value of 43 percent and many values between 10 and 30 percent in the southern wetland complex). The breakdown of these organics consumes oxygen and results in

Together, anoxic (reducing) conditions and available organic carbon yield an environment favorable for binding of metals, rendering them unavailable for uptake by organisms (ITRC 2011). Lead (as well as other divalent metals: copper, cadmium, nickel, zinc, and silver) is subject to binding/ sequestration in the presence of acid volatile sulfide (AVS), often found in anoxic wetland sediment. While food web modeling results identify potential risks related to lead in soil and sediment, the conservative assumptions on which the HQs are based, particularly those related to bioavailability, likely overestimate potential risks. The inorganic forms of lead used onsite during historical operations and reducing onsite aquatic habitat conditions likely constrain lead bioavailability, as do other habitat conditions that facilitate metals sequestration (e.g., high organic carbon content).

Historical fill is known to contain PAHs and metals (N.J.A.C. 7:26E – NJDEP TRSR). Historical fill materials were used during early development of the Facility to raise ground surface elevations. The SDA, where both PAHs and metals appear more prevalent in sediment, drains much of the former operational area of the Facility where large amounts of historical fill have been mapped (Hercules 2007, 2016a).

Surface water drains through shallow ditches cut into the filled valley floor. PAHs and metals in SDA sediments may be influenced by non-Facility-related sources as well. The RI has documented these constituents in stormwater runoff from adjacent roadways (i.e., Route 46 and Howard Boulevard) that directly discharge to a series of ditches in the SDA (Hercules 2007). Physical and chemical conditions onsite, like those outlined above for lead, likely limit bioavailability of these potential secondary risk drivers.

The Facility history, previous reports (Hercules 2007), and CSM (Section 3.1) establish links between the terrestrial and aquatic exposure areas used in this ERA. The RIRs (Hercules 2007) identified lead as a “frequent exceedance” constituent in soil, sediment, and surface water. Thus, the appearance of similar constituents (lead in particular) as potential risk drivers confirms historical findings and further informs an understanding of COPEC fate, transport, and exposure pathways.

Section 8: Uncertainty Analysis

In a risk assessment, uncertainty exists. Sources of uncertainty include:

- Natural variability of ecological systems
- Incomplete knowledge of site-specific fate and transport mechanisms and biological processes
- Use of organism-specific TRVs to evaluate potential population level effects
- Use of generic bioaccumulation factors and models to estimate uptake of COPECs at the Facility

Following submission of the 2016 EE/ERA, Hercules conducted multiple focused field sampling events to address uncertainties in the risk assessment process and refine risk characterization results. The results of the activities are incorporated into this document and have supplemented and/or replaced certain generic or theoretical values with site-specific empirical data and reduced the level of uncertainty. Nevertheless, some level of uncertain always exists, and the scale of the Facility and exposure areas lends a degree of uncertainty unique to this risk assessment. The preparers of this updated ERA (**Attachment 12**) have relied on expertise, experience, and technical guidance to identify areas of uncertainty and manage the influence of that uncertainty in the risk characterization.

Uncertainties potentially influencing results of the ERA are briefly described below.

8.1 Complexity of Natural Systems

Natural systems are complex and involve the interaction of several physical, chemical, and biological elements. The ERA uses simplifying assumptions to attempt to model these interactions. Direct measurements of COPEC concentrations are used along with information from scientific literature to model the interactions that may be occurring in natural systems. The assumptions made and models used, and how well or poorly these assumptions and models reproduce the interactions taking place in the natural system, introduce uncertainty in the ERA. An effort has been made to use conservative assumptions to bias potential risk to ecological receptors toward overestimation.

8.2 Data Uncertainty

The ERA makes use of the SI/RI dataset collected between 1999 and 2013. These data were collected in support of general site characterization activities; not specifically to assess ecological risk. As such, certain limitations are inherent in the existing dataset that contribute uncertainty to the results of the ERA.

The overall approach of the ERA focuses the assessment on areas of the Facility where potential ecological risk is uncertain. To achieve this focus, data representative of undeveloped areas outside the Remedial Area boundary and data from areas where Hercules is committed to active remediation (APRAs) to address Facility-related influences were removed from the ERA dataset. The evaluation of potential ecological risk at the Facility using the parsed dataset introduces uncertainty to the process. However, the commitment to implement a remedy protective of human

health and the environment in APRAs addresses ecological risk with a greater degree of certainty than estimating risks via the methods outlined in this ERA.

Samples collected early in the SI/RI process were analyzed for a full constituent list per regulatory requirements. As the investigation progressed, the analyte list was reduced based on previous findings to focus on Facility-related constituents. Presumably, if the constituents were not analyzed for, detections were below screening standards at the time those decisions were made. This situation contributes a degree of uncertainty to the ERA.

Analytical data resulting from a preliminary investigation of free or residual product (i.e., motor oil, diesel fuel, No. 6 fuel oil, gasoline, hydrocarbons as mineral spirits, and total petroleum hydrocarbons) were reported for six samples in the database. Results were non-detect for these analytes (except motor oil). Motor oil has not been carried forward as a COPEC because it represents a combination of individual PAH constituents represented elsewhere in the dataset, and toxicology information specific to motor oil is not available to support food web modeling.

Finally, the SI/RI sediment dataset represents the 0- to 1-foot sample interval. The BAZ in sediment is generally considered the 0- to 0.5-foot interval and occasionally extends to the 1 foot-depth based on geochemical conditions in the sediment (e.g., redox potential). Data from the deeper component of the interval may not represent the most recently deposited sediment and/or the BAZ and may have been deposited decades ago during the Facility's operational history. The correlation of constituent concentrations in sediment between 0.0 to 0.5 and 0.5 to 1 foot is unknown and contributes a degree of conservatism and uncertainty to the ERA. More contemporary sediment analytical data collected in support of the ERA has targeted the surface sediment interval and serves to reduce the above-referenced uncertainties.

8.2.1 COPEC Screening Process

The COPEC screening process involved a sequential analysis of the dataset to retain constituents for consideration in the ERA. Constituents detected in at least five samples and that exceeded their respective benchmark (or lacked a screening benchmark) were retained as COPECs. Constituents that were detected in less than five samples were not retained as COPECs. **Tables 5-1 through 5-5** summarize statistical information for the constituents with low detection frequencies in each exposure medium. Although some of these constituents have detection limits that are higher than associated screening values, many of these constituents are volatile, can be associated with laboratory techniques, are tentatively identified compounds, and/or have limited toxicity. Given the size of the site characterization dataset, elimination of these infrequently detected constituents contributes negligible uncertainty to the assessment.

COPEC screening considered the number of detects and maximum detected concentration. Based on the comprehensive nature of the dataset, non-detect reporting limits were not considered in the COPEC selection process. As such, some constituents that were not retained as COPECs possessed a maximum non-detect reporting limit greater than the associated ESB. Thus, the potential exists for this process to underestimate risk. However, inclusion of these data by relying on assumptions regarding the actual concentration that may be present would also introduce significant uncertainty to the assessment, and the overall size and comprehensive nature of the dataset limit the likelihood of these false negatives.

Potential risk associated with several constituents could not be quantitatively evaluated because screening benchmarks were unavailable. A list of commonly used ESB sources were evaluated, as well as constituent- and class-specific peer-reviewed literature and publicly available

documents, without identifying an appropriate ESB. Little is known about the environmental fate, transport, and/or toxicity for many of these constituents; or the information available indicates that these constituents are unlikely to pose significant risk to ecological receptors. Limited toxicity and/or scientific information for certain constituents results in some uncertainty, and the magnitude of any potential for risk is unknown.

Beyond a comparison of constituent concentrations to ESB, constituent-specific information was used to further refine the list of COPECs carried through the ERA, as presented below:

- As described in Section 4.1.2, some constituents appeared on multiple analyte lists, resulting in multiple data points at the same location. A combination of technical and regulatory information was used to select the more conservative and representative (e.g., accurate and precise) data for use in the ERA.
- The maximum detected concentration of aluminum exceeded its associated generic ESB. Risk guidance (USEPA 2003b) indicates that soluble aluminum in soil can pose a potential risk to ecological receptors, and that soil pH below 5.5 dictates aluminum solubility and therefore bioavailability. As such, information regarding the pH of Facility soil was evaluated prior to retaining aluminum as a COPEC. The 95UCL calculated for Facility soil from field (pH = 5.8) and laboratory samples (pH = 6.1) was greater than 5.5; therefore, aluminum was not retained as a COPEC.

The refined risk characterization presented in this document builds upon the work done in the 2016 EE/ERA, and incorporates site-specific data collected in support of the ERA. This information provides for a shift from generic screening benchmarks to site-specific measures of potential toxicity and/or bioavailability that better inform COPEC retention and associated risk characterization.

8.2.2 Exposure Point Concentrations

The COPEC screen identified COPECs based on the maximum detected constituent concentration. EPCs used in the food web models were calculated using the 95UCL (or maximum detected concentration in the absence of sufficient data for statistical analysis). The size of the available datasets introduces uncertainty to the development of one point concentration representative of exposures across the entire exposure area.

For many COPECs, orders of magnitude differences occur when calculating HQs using the maximum concentration and the 95UCL (**Tables 5-1 through 5-5**). While the direction and magnitude of this uncertainty are not completely measurable across receptor groups, the use of the maximum concentration or the 95UCL may overestimate risk.

8.2.3 Exposure Areas

The habitat quality within each exposure area varies. In general, natural areas and those forested areas that served as buffers between historical operational areas provide higher quality habitat, while the former operational areas consist of disturbed lands with early successional vegetation and provide habitat of lesser quality. The quality of the habitat is often consistent with the quality of the environmental media within. That is, areas of poorer quality habitat often coincide with areas of former Facility operations and influences, resulting in higher COPEC concentrations and a greater characterization sample density. Conversely, COPEC concentrations and sampling

density in buffer areas that often provide higher quality habitat are generally lower. Food web models assume that wildlife receptors spend equal amounts of time in useable habitat areas of the Facility. In reality, wildlife receptors may prefer the higher quality habitat for cover, forage resources, and other ecological advantages that it affords. These assumptions inherent to the food web models may overestimate risk.

Risk assessment requires assumptions regarding the extent to which organisms are exposed to constituents at the Facility. The exposure parameters used to conduct food web modeling for birds and mammals were selected to represent conservative feeding strategies for each of the selected receptors. These exposure parameters are not Facility-specific, although an attempt was made to reflect actual Facility conditions to the extent possible. For example, relevant information about regional diet was considered. Site-specific habitat characteristics (e.g., availability, distribution, and quality of food) influence feeding strategies and, therefore, exposure parameters, resulting in uncertainty attributable to the use of generic exposure parameters. To the extent practicable, the acreage of available habitat types has been incorporated into the AUF calculation to reduce uncertainty.

8.2.4 Uptake Factors

Apart from Facility-specific concentrations of copper and lead in aerial insect tissue in aquatic exposure areas, this ERA uses literature-derived BAFs and BSAFs to estimate tissue concentrations for soil/sediment invertebrates, plants, small mammals, and fish tissue. For soil, literature-based BAF models from USEPA (1999 and 2007) were used. For sediment, BSAF data were obtained from the USACE BSAF database (USACE ERDC EL 2011).

Non-site-specific and modeled accumulation factors introduce a high degree of uncertainty. Furthermore, BSAFs are highly variable and dependent upon the species tested, lipid content of the organism, and organic carbon content of the sediment. Values selected from the USACE BSAF database are based on data collected at different sites and across ranges of species that likely do not reflect uptake under the conditions at the Facility. To date, only non-polar organic compounds have been shown to uphold the relationship between sediment organic content and tissue lipids, and even these constituents show a wide variation in BSAF values (USACE ERDC EL 2011). The direction and magnitude of this uncertainty are not measurable.

8.2.5 Explosive and Energetic Compounds

Despite more than 100 years of E&E material production onsite, potential ecological risks related to E&E compounds are generally low. There are several reasons for this:

- TNT, the most prominent E&E constituent identified in the SI/RI, occurs in one of the Areas of Presumed Remedial Action that will undergo remediation. As such, the TNT data representing the most substantially influenced areas of the Facility were not considered in the ERA. The chemical and biological breakdown of TNT is a source of the DNT and amino-DNT constituents onsite. Thus, these constituents are frequently co-located and, by excluding areas of highest TNT concentrations, the highest concentrations of DNTs and amino-DNTs were removed as well.

- Most E&E compounds will degrade via natural weathering and through time. The Facility was decommissioned between 1996 and 2003; therefore, natural recovery has been occurring at the Facility. In addition, E&E compounds are capable of being metabolized by biological processes. These processes form the basis of the soil bioremediation remedy underway in the TNT APRA.
- Many E&E compounds that were detected at the Facility were screened out of media during the COPEC screen due to their low toxicity (relatively high ESBs).
- Several E&E compounds were carried through the COPEC screen and into the food web models because they lacked ESB. They were then modeled to upper-trophic-level receptors but, because they lack bioaccumulative properties, could not be assessed further.

As a result of the low toxicity/low bioavailability and propensity of E&Es to be metabolized or degraded over time, most E&Es released at the Facility are unlikely to pose potential ecological risk. However, there is some uncertainty for E&E constituents with laboratory detection limits greater than ESB, and/or those for which ESB are unavailable. The effect of this uncertainty on the ERA is unknown.

8.2.6 Toxicity Reference Values

This ERA uses toxicological data that were collected on an individual basis, not at the population level. Therefore, the HQs represent potential risks to single species of organisms, not to a population or community. However, potential risks were extrapolated to include the entire population as a whole. In general, species selected for study are those with a high degree of sensitivity to the chemical exposure being evaluated, resulting in benchmarks that are protective of sensitive species and conservative when used for the general population conditions.

In addition, the majority of evaluated toxicity data, obtained from literature values, were derived from laboratory studies conducted in settings that do not mimic true field conditions. Laboratory studies typically control various factors in order to isolate one particular parameter. Although such controlled experiments make it simpler to interpret isolated parameters or relationships, uncertainty is associated with assuming that laboratory exposure conditions are equivalent to in-field exposure conditions. TRVs are typically based on laboratory dosing studies in which highly soluble forms of the COPECs were used. As a result, these toxicity estimates can overestimate the bioavailability, uptake, and ultimate toxicity of a particular COPEC. However, for the ERA, it is assumed that the TRVs represent actual exposures to the receptors evaluated. As such, potential risks are likely overestimated.

Section 9: Conclusions & Recommendations

This ERA assesses potential ecological risk attributable to historical operational influences in formerly developed areas of the Facility. The risk characterization for lower-trophic-level receptors compares COPEC concentrations in exposure media to ESBs. For upper-trophic-level wildlife receptors, the estimated exposure (i.e., daily dietary dose) of each COPEC to potential wildlife receptors is compared to literature-based TRVs. Where applicable, a weight-of-evidence approach considers multiple lines of evidence to support risk characterization and conclusions.

9.1 Conclusions

An interpretation of HQ values relative to each AE and ME is presented below.

- **AE 1.** *Could direct contact with COPECs in Facility soil affect the structure, function, and/or survival of the terrestrial plant community?*
  - Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to terrestrial plant communities by exposure to COPECs at the Facility are possible.
  - This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.
  - This conclusion is supported by the following ME:
    - ✓ HQs resulting from a comparison of soil COPEC concentrations to ESBs protective of terrestrial plants were greater than 1 for 7 metals; HQs ranged from 2 to 32, with the greatest potential for risk from mercury (32)[9], chromium (24), and vanadium (17).
- **AE 2.** *Could direct contact with COPECs in Facility soil affect the structure, function, and/or survival of the terrestrial invertebrate community*?
  - Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to terrestrial invertebrate communities by exposure to COPECs at the Facility are unlikely.
  - This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

[9] Calculated HQs are presented in parentheses next to each COPEC to show magnitude of potential to cause adverse effects; in other words, the larger the number, the greater the likelihood that adverse effects are possible.

- This conclusion is supported by the following ME:

  - ✓ HQs resulting from a comparison of soil COPEC concentrations to ESBs protective of terrestrial invertebrates were less than 1 for COPECs, with the exception of manganese (8), copper (2), vanadium (2), and zinc (2).

- **AE 3.** *Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of herbivorous avian and mammal populations*?

  - Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to herbivorous avian and mammal populations by exposure to COPECs at the Facility are unlikely.

  - This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

  - This conclusion is supported by the following MEs:

    - ✓ HQ_{NOAELs} and HQ_{LOAELs} for northern bobwhite, an herbivorous bird, are less than 1.

    - ✓ HQ_{NOAELs} and HQ_{LOAELs} for white-tailed deer, an herbivorous mammal, are less than 1.

- **AE 4.** *Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of insectivorous avian and mammal populations*?

  - Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to insectivorous avian populations by exposure to COPECs at the Facility are possible, but adverse effects to mammal populations by exposure to COPECs at the Facility are unlikely.

  - This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk. This conclusion is supported by the following MEs:

    - ✓ HQ_{NOAELs} for American robin, an insectivorous bird, are less than 1, with the exception of lead (9) and copper (2). HQ_{LOAELs} for American robin are less than 1, with the exception of lead (5).

    - ✓ HQ_{NOAELs} for short-tailed shrew, an insectivorous mammal, are less than 1, with the exception of lead (2). HQ_{LOAELs} for short-tailed shrew are less than 1.

- **AE 5.** *Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of carnivorous avian and mammal populations*?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to carnivorous avian and mammal populations by exposure to COPECs at the Facility are unlikely.

  – This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

  – This conclusion is supported by the following MEs:

    ✓ HQ_{NOAELs} and HQ_{LOAELs} for red-tailed hawk, a carnivorous bird, are less than 1.

    ✓ HQ_{NOAELs} and HQ_{LOAELs} for red fox, a carnivorous mammal, are less than 1.

✓ **AE 6.** *Could direct contact with COPECs in sediment in each subdrainage area affect the structure, function, and/or survival of the benthic invertebrate community*?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to benthic invertebrate communities by exposure to COPECs are possible in Unnamed Ponds, Central Drainage Basin, Maintenance – Dynamite Area – West, and Maintenance NG Area; and unlikely in the nine remaining subdrainage areas.

  – This is a reasonable finding based on the evaluation of multiple LOEs evaluated to characterize risk to the benthic invertebrate community, the uncertainty inherent to the exposure and effects assessment process, and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

  – This conclusion is supported by the following MEs:

    ✓ HQ_{LELs} resulting from a comparison of NDA subdrainage area sediment COPEC concentrations to ESBs protective of benthic invertebrates were greater than 1 for eight COPECs.

    ✓ In NDA subdrainage areas, supplemental evaluation of the benthic invertebrate biodiversity LOE identified HGMI (7.65), H’ (1.72), J’ (0.37), ENS (5.59) and abundance (37) metrics in Unnamed Ponds lower than Facility-specific reference thresholds for non-flowing habitat (reference lower bound; HGMI = 19.5, H’ = 1.93, J’ = 0.48, ENS = 6.86, abundance = 181.7), indicating reduced benthic biodiversity in Unnamed Ponds.

- HQ_{LELs} and supplemental evaluation of arsenic background threshold, sediment chemistry, and chemical speciation LOEs in Unnamed Ponds indicate the greatest potential for adverse benthic invertebrate community effects are from arsenic (4) and mercury (8).

✓ HQs resulting from a comparison of SDA subdrainage area sediment COPEC concentrations to ESBs protective of benthic invertebrates were greater than 1 for nine COPECs.

✓ Supplemental evaluation of the benthic invertebrate biodiversity LOE in SDA subdrainage areas evaluated biodiversity indices as follows:

- In the Maintenance NG Area, HGMI (14.1), H' (1.64), J' (0.39), and ENS (5.22) metrics were lower than Facility-specific reference thresholds for flowing habitat (reference lower bound; HGMI = 20.1, H' = 3.52, J' = 0.68, ENS = 34.0), indicating reduced benthic biodiversity in Maintenance NG Area.
  - HQ_{LELs} and supplemental evaluation of arsenic background threshold, sediment chemistry, and chemical speciation LOEs in Maintenance NG Area indicate the greatest potential for adverse benthic invertebrate community effects are from arsenic (2), mercury (11), and silver (3).
- In the Central Drainage Basin, H' (1.45), J' (0.35), and ENS (4.26) metrics are lower than Facility-specific reference thresholds for flowing habitat (reference lower bound; H' = 3.52, J' = 0.68, ENS = 34.0) and non-flowing habitat (H' = 1.93, J' = 0.48, ENS = 6.86). Additionally, abundance (65) in Central Drainage Basin is lower than the Facility-specific threshold for non-flowing habitat (181.7). These metrics indicate reduced benthic biodiversity in the Central Drainage Basin.
  - HQ_{LELs} and supplemental evaluation of arsenic background threshold and chemical speciation LOEs in the Central Drainage Basin indicate the greatest potential for adverse benthic invertebrate community effects are from arsenic (7) and mercury (20).
- In Maintenance Dynamite Area - West, H' (2.46), J' (0.57), and ENS (11.6) metrics are lower than Facility-specific reference thresholds for flowing habitat (reference lower bound; H' = 3.52, J' = 0.68, ENS = 34.0).
  - HQ_{LELs} and supplemental evaluation of arsenic background threshold, sediment chemistry, and chemical speciation LOEs in the Central Drainage Basin indicate the greatest potential for adverse benthic invertebrate community effects are from arsenic (7) and mercury (20).

- **AE 7.** *Could direct contact with COPECs in sediment in each subdrainage area affect the survival and function of aquatic plant populations*?

- Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to aquatic plants in the NDA and SDA subdrainage areas are as follows:

    - ✓ In the NDA, adverse effects to aquatic plants are possible in each of the five subdrainage areas (i.e., Duck Pond, Eastern and Western Tributaries, Northeast Ponds, and Unnamed Ponds).

    - ✓ In the SDA, adverse effects to aquatic plants are possible in eight subdrainage areas (i.e., Central Drainage Basin, Maintenance - Dynamite Areas – East and West, Maintenance – NG Area, Miscellaneous Offsite Streams – Lower and Upper, and TNT-PETN-NG Ditches); and unlikely in the Development Area Stream.

- This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk and considering ESBs for aquatic plants are based on toxicity to terrestrial plants.

    - This conclusion is supported by the following MEs:

        - ✓ HQs resulting from a comparison of NDA subdrainage area sediment COPEC concentrations to ESBs protective of terrestrial plants are greater than 1 for 7 COPECs; HQs ranged from 2 to 6, with the greatest potential for adverse effects from silver.

        - ✓ HQs resulting from a comparison of SDA subdrainage area sediment COPEC concentrations to ESBs protective of terrestrial plants were greater than 1 for 18 COPECs; HQs range from 2 to an HQ_{max} of 46,429, with the greatest potential for adverse effects from pyrene.

- **AE 8**. *Could direct contact with COPECs in surface water in each subdrainage area affect the survival and reproduction of fish and aquatic invertebrate populations?*

    - Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis in the NDA Subdrainage Areas indicate that adverse effects to fish populations by exposure to COPECs are possible but unlikely in Duck Pond, Eastern Tributary, Northeast Ponds, and Unnamed Ponds; and likely in Western Tributary.

    - Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis in the SDA subdrainage areas indicate that adverse effects to fish populations by exposure to COPECs are unlikely in eight subdrainage areas (i.e., Central Drainage Basin, Development Area Stream, Maintenance Dynamite Areas – East and

West, Maintenance – NG Area, Miscellaneous Offsite Streams – Lower and Upper, and TNT-PETN-NG Ditches).

- This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

- This conclusion is supported by the following measurement endpoint:

  - ✓ HQs resulting from a comparison of NDA Subdrainage Area surface water COPEC concentrations (dissolved phase) to ESBs protective of fish populations are as follows:

    - In Duck Pond, Eastern Tributary, Northeast Pond, and Unnamed Ponds, COPEC HQs were less than 1.

    - In Western Tributary, COPEC HQs were less than 1, with the exception of copper (3), lead (2), and zinc (2).

  - ✓ HQs resulting from a comparison of SDA Subdrainage Area surface water COPEC concentrations (dissolved phase) to ESBs protective of fish populations were less than or equal to 1 for all COPECs in all SDA Subdrainage Areas.

- **AE 9.** *Could food-web transfer of COPECs in sediment in each subdrainage area adversely affect reproductive success or survival of herbivorous avian and mammal populations?*

  - Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to herbivorous avian and mammal populations by exposure to COPECs are unlikely in NDA subdrainage areas, and possible in SDA subdrainage areas.

  - This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

  - This conclusion is supported by the following MEs:

    - ✓ NDA subdrainage area HQ_{NOAELs} for mallard duck, an herbivorous bird, are less than 1.

    - ✓ NDA subdrainage area HQ_{NOAELs} for muskrat, an herbivorous mammal, are less than 1.

    - ✓ SDA subdrainage area HQ_{NOAELs} for mallard duck, an herbivorous bird, are less than 1.

- ✓ SDA subdrainage area HQ_{NOAELs} for muskrat, an herbivorous mammal, are less than 1, with the exception of:

  - Pyrene in six subdrainage areas (range; HQ_{NOAEL}: 4 – 8). Of these subdrainage areas, pyrene HQ_{LOAEL} is greater than 1 in one subdrainage area (Central Drainage Basin; HQ_{LOAEL} = 2).

  - Fluoranthene in four subdrainage areas (range; HQ_{NOAEL}: 4 – 9). Of these subdrainage areas, fluoranthene HQ_{LOAEL} is greater than 1 in one subdrainage area (Central Drainage Basin; HQ_{LOAEL} = 2).

- **AE 10.** *Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of insectivorous avian and mammal populations?*

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to insectivorous avian and mammal populations by exposure to COPECs are possible in NDA subdrainage areas and unlikely in SDA subdrainage areas.

  – This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

  – This conclusion is supported by the following MEs:

    - ✓ NDA HQ_{NOAELs} for tree swallow, an insectivorous bird, are less than 1.

    - ✓ NDA subdrainage area HQ_{NOAELs} for little brown bat, an insectivorous mammal, are less than or equal to 1, with the exception of:

      - lead in one subdrainage area (Eastern Tributary; HQ_{NOAEL} = 5). In this subdrainage area, lead HQ_{LOAEL} is greater than 1 (HQ_{LOAEL} = 3).

      - copper in one subdrainage area (Eastern Tributary; HQ_{NOAEL} = 3). In this subdrainage area, copper HQ_{LOAEL} is greater than 1 (HQ_{LOAEL} = 2).

      - arsenic in one subdrainage area (Unnamed Ponds; HQ_{NOAEL} = 2). In this subdrainage area, arsenic HQ_{LOAEL} is less than or equal to 1.

    - ✓ SDA subdrainage area HQ_{NOAELs} for tree swallow, an insectivorous bird, are less than 1.

    - ✓ SDA subdrainage area HQ_{NOAELs} for little brown bat, an insectivorous mammal, are less than or equal to 1.

- **AE 11.** *Could food-chain transfer of COPECs in sediment in each area adversely affect reproductive success or survival of piscivorous avian and mammal populations?*

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to:

    ✓ Piscivorous avian populations by exposure to COPECs in NDA subdrainage areas are unlikely.

    ✓ Piscivorous mammal populations by exposure to COPECs in NDA subdrainage areas are possible but unlikely.

    ✓ Piscivorous avian populations by exposure to COPECs in SDA subdrainage areas are possible but unlikely.

    ✓ Piscivorous mammal populations by exposure to COPECs in SDA subdrainage areas are possible.

  – This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

  – This conclusion is supported by the following MEs:

    ✓ NDA subdrainage area HQ_{NOAELs} for great blue heron, a piscivorous bird, are less than or equal to 1.

    ✓ SDA subdrainage area HQ_{NOAELs} for great blue heron, a piscivorous bird, are less than or equal to 1.

    ✓ NDA subdrainage area HQ_{NOAELs} for mink, a piscivorous mammal, are less than or equal to 1.

    ✓ SDA subdrainage area HQ_{NOAELs} for mink, a piscivorous mammal, are less than or equal to 1, with the exception of:

      ○ Lead in seven subdrainage areas (HQ_{NOAEL}: 2). In these subdrainage areas, lead HQ_{LOAELs} are less than or equal to 1.

      ○ Fluoranthene in one subdrainage area (Central Drainage Basin; HQ_{NOAEL} = 6). In this subdrainage area, fluoranthene HQ_{LOAEL} is less than or equal to 1.

      ○ Pyrene in one subdrainage area (Central Drainage Basin; HQ_{NOAEL} = 4). In this subdrainage area, pyrene HQ_{LOAEL} is less than or equal to 1.

9.2 Recommendations

Section 1.2 outlined the approach to this ERA that focused: A) risk characterization in areas where risk was uncertain, and B) on the identification and assessment of localized areas driving potential risk. These actions segregated the Facility into the following areas:

1. Areas within the Remedial Area not designated as APRAs (the focus of this document)
2. Areas of Presumed Remedial Action
3. Areas Beyond the Remedial Area Boundary

Hercules' site closure strategy relied on through the completion of the SI and RI maintained a similar focus – sitewide characterization to identify areas that pose the greatest potential risk to human health and environment, followed by pre-remedial design work to refine the areal extents and inform remedy selection and design. Hercules acknowledges that closure of the Facility through CSRR requires addressing compliance across each of the three areas noted above.

Recommendations for ecological risk-related activities in each of these areas are presented in the following subsections. Recommendations maintain a focus on the assessment of specific areas (and COPECs) driving risk, with the objectives of supporting a weight-of-evidence approach to refining risk estimates and arriving at a scientifically-based risk management decision regarding the need for and scope of ecologically-based remedial actions.

9.2.1 Areas within the Remedial Area not designated as APRAs

Based on the conclusions presented in Section 9.1, additional ERA activities are recommended in both terrestrial and aquatic exposure areas. Specific risk conclusions and the associated proposed next steps are outlined below.

9.2.1.1 Terrestrial Exposure Area

Recommended action items and next steps in terrestrial exposure areas include:

1. **Spatial analysis of soil COPEC concentrations in terrestrial habitats:** To refine potential risk estimates to upper-trophic-level terrestrial receptors whose smaller home range sizes may lead to spatial exposure variability in the Facility-wide terrestrial exposure area (i.e., short-tailed shrew and northern bobwhite), spatial analysis of soil COPEC concentrations in terrestrial habitat patches and literature-derived population density is recommended. The framework of this approach was initiated in this ERA for northern bobwhite (as detailed in Section 5.1.1.1.2). **Figures 5-2** and **5-4** are a visual representation of anticipated future desktop activities, where Thiessen polygons were calculated for soil data within northern bobwhite habitat, datasets within each home range buffer will be evaluated for ecological risk. This analysis represents the initial step toward spatial analysis of soil COPEC concentrations and an evaluation of COPEC concentrations in home range-specific buffers for upper-trophic-level receptors and prey items.

2. **Invertebrate and plant community field evaluations in localized areas:** To further refine existing conclusions for terrestrial invertebrate and plant communities, a desktop evaluation is recommended to: 1) identify habitat types in which soil COPECs disproportionately influence potential ecological risk to terrestrial plant communities, and in which terrestrial plant community surveys may be warranted, and 2) identify AoEs for four COPECs (i.e., copper, manganese, vanadium, and zinc) driving potential risk to soil invertebrates in the Facility-wide terrestrial exposure area and develop a field program to provide additional LOEs specific to these COPECs and receptors (e.g., bioavailability and toxicity). The spatial analysis (Item 1) will assist in this evaluation.

3. **Invertebrate prey tissue collection and analyses:** To further refine existing conclusions for upper-trophic-level terrestrial insectivores (i.e., American robin and short-tailed shrew), invertebrate tissue collection and analyses are recommended to provide site-specific prey tissue concentrations in terrestrial insectivore food web models (i.e., American robin and short-tailed shrew). Collection locations will be biased across the range of COPEC concentrations and informed via the results of spatial analysis recommended in Item 1.

No further evaluation is warranted for carnivorous bird and mammal receptors in the terrestrial exposure area.

9.2.1.2 Aquatic Exposure Areas

Recommended action items and next steps in aquatic exposure areas include:

7. **Aquatic plant refined risk characterization and growth inhibition bioassays:** To further refine existing conclusions for aquatic plant communities, a stepwise evaluation is recommended to further refine aquatic plant risk characterization in various subdrainage areas. The stepwise evaluation would include a desktop evaluation of ESBs incorporating literature-derived NOEC concentrations, followed by growth inhibition bioassays of field-collected porewater in subdrainage areas where potential risk to aquatic plants remains uncertain following abovementioned desktop refinement.

8. **Sediment porewater COPEC speciation, bioavailability, and toxicity evaluations:** To further refine existing conclusions for benthic invertebrate communities, porewater sample collection is recommended to assess COPEC form, bioavailability and toxicity. Initial efforts will focus on evaluating speciation of arsenic and silver and partitioning of COPECs from sediment to porewater. If necessary, toxicity testing of field-collected porewater would be used as an additional LOE regarding potential benthic invertebrate risk from three sediment COPECs (i.e., arsenic, mercury, and silver).

9. **Desktop evaluation and aquatic invertebrate and fish habitat evaluation:** For dissolved copper, a desktop evaluation incorporating USEPA's (2007) Copper Biotic Ligand Model and site-specific water quality parameters is recommended to refine potential risk estimates to fish and aquatic invertebrates. Variations in hydrology in the Western Tributary subdrainage area throughout the seasons may preclude the ability of the habitat to sustain fish populations. To this end, a hydrology study is recommended to better align receptors with available habitat. The hydrology study could include time-series

surface water sampling for total and dissolved lead and zinc to refine risk estimates for water-column invertebrates.

10. **Probabilistic risk evaluation, aquatic plant surveys, and tissue collection:** To further refine existing conclusions for herbivorous mammals in aquatic exposure areas (i.e., muskrat), aquatic vegetation surveys are recommended to delineate foraging habitat in SDA subdrainage areas. Literature-derived population density and spatial distributions of edible biomass and sediment COPEC concentrations will be incorporated in spatial analysis to evaluate probabilistic risk distributions. In subdrainage areas where risk remains uncertain following probabilistic analysis, aquatic plant tissue collection and analyses may be necessary to refine the muskrat food web model.

11. **Probabilistic risk evaluation and fish tissue collection:** For piscivorous mammals in aquatic exposure areas (i.e. mink), spatial analysis of sediment COPEC concentrations in aquatic habitat patches and literature-derived population density is recommended to evaluate probabilistic risk distributions. In subdrainage areas where risk remains uncertain following probabilistic analysis, fish tissue collection and analyses are recommended to further refine the mink food web model.

12. **Aerial invertebrate tissue collection and analyses:** For insectivorous mammals in aquatic exposure areas (i.e., little brown bat), additional aerial insect tissue collection and analyses for three COPECs (i.e., arsenic, copper, and lead) are recommended to refine insectivorous food web models for certain subdrainage areas.

9.2.2 Areas of Presumed Remedial Action

As presented in **Attachment 2**, Hercules continues to advance pre-design, design, permitting, and implementation activities in APRAs identified through the RI/ERA process. Remedy selection, extents, and remediation goals will incorporate both human health and ecological endpoints and remain protective of human health and the environment. Remedial action work plans for specific APRAs will be submitted to NJDEP via e-portal, consistent with the approach taken for the TNT and PCB remedies to date.

9.2.3 Areas Beyond the Remedial Area Boundary

Additional data collection is ongoing in the Areas Beyond the Remedial Area Boundary exposure area, with a sampling event scheduled for Fall 2025. Following receipt of sampling results, the ERA of this area will be updated as follows: A), COPEC screen using the updated dataset, B) evaluating discontinuous areas as individual exposure areas (e.g., uplands along Rt 46, western ridgeline, eastern ridgeline, northern undeveloped area), C) assessing dataset composition (e.g., outliers) for each exposure area, and D) providing recommendations on an area-by-area basis to address potential ecological risks (e.g., HQ>1), if identified.

Tables

Table 2-1 - Areas of Presumed Remedial Action
Ecological Risk Assessment
Kenvil Works Facility
Kenvil, New Jersey

	Area of Presumed Remedial Action	History	Fate and Transport	Remedial Objective
Tier I	TNT Area (conglomerate of adjacent areas of concern)	One of the earliest developed portions of the Facility as well as the Facility of one of the most powerful explosions in the history of the Facility. This area of the Facility produced explosives for more than a century; during this period operational procedures and incidental release of materials affected soil and groundwater quality. Areas of stressed vegetation, as well as areas devoid of vegetation (former footprint of Building 666 that exploded in 1917) are visible. Stained soil and discolored water have been observed in a former lagoon area (depression in ground surface) where overburden groundwater interacts with surface soil and discharges becoming surface water.	Constituent distribution in this areas occurred primarily during process upsets (e.g., explosions, spills). Following these incidents, the ground surface was leveled and new structures built, these activities further distributed source material (e.g., crystalline TNT, inorganic lead chunks) into the upper few feet of the soil column. Over time, precipitation mobilized constituents in soil to groundwater. TNT in soil influences groundwater quality in this area of the Facility. Groundwater discharges to the southern wetland complex adjacent to the Dynamite/TNT area. The absence of source area constituents in these wetland features is likely related to strong reducing conditions in sediment and associated biological degradation of dissolved phase constituents as groundwater discharges through the sediment. In the southwestern corner of the Facility.	Hercules is evaluating a combination of source removal, bioremediation, and monitored natural attenuation to address constituent concentrations (primarily TNT and its breakdown products) in this area.
Tier II	Ammonium Nitrate Area – Former Burning Ground and intervening areas of concern (H12-237, H13-1, H13-7)	From the beginning of production onsite through the end of WWI, off-specification product and residual materials were transported via rail car to the WWI Burning Grounds (near the AN Area and wastewater treatment plant). The contents of the rail car were emptied down a slope where the materials were incinerated in place on the ground surface. Currently, the area supports sparse vegetation and the ground surface contains a non-combustible fraction of the waste materials (e.g., ceramic, metal) and related constituents in soil (e.g., metals, PAHs).	Given the surficial nature of the activities conducted in this area, debris and constituents in soil do not extend beyond the surface soil. No interaction with groundwater is evident, and would not be expected based on the topography of the area and associated groundwater table elevations. In the absence of vegetation, erosion of surficial soil is possible and may result in localized transport of constituents at/near the perimeter of the area of concern.	The presumptive remedy for this area involves excavation of soil and comingled debris, backfilling with clean fill and restoration of vegetative cover. Excavated material may be disposed of offsite or consolidated and contained elsewhere onsite. Additional study is needed to guide final disposition of the excavated material.
Tier II	B-Line Area – Disposal Area (M8-1)	This area served as a disposal area for solid waste materials during the period of increased production surrounding World War II (WWII). The area currently consists of a low-lying depression with visible surface debris. Vegetation is moderate to sparse and consists of grasses and shrubs. The area occurs between Duck Pond and an emergent/forested wetland complex.	The groundwater table is at or near the ground surface in this areas throughout the year. The material disposed of consists of empty metal containers, concrete debris, and off-spec fiberglass motor housings. This debris, while potentially emplaced below the groundwater table, are not expected to contain constituents that would leach to groundwater. Groundwater monitoring wells in proximity to the disposal area confirm this expectation.	The presumptive remedy will include a combination of removal and offsite disposal, debris consolidation and capping while minimizing disturbance to freshwater wetlands. Pre-design investigation activities will include test pitting to refine the perimeter of the disposal area and further characterize the emplaced material.
Tier II	Development Area – Old Burning Ground and adjacent areas of concern to the southwest (M5-3, L5-2313, L5-10, L5-2275, L5-539)	The burning area was used to dispose off-spec and residual energetic materials and was situated in a low-lying area adjacent to Duck Pond. Duck Pond provided a source of water and a buffer from nearby forested areas. Currently, the area supports sparse vegetation and the ground surface contains a non-combustible fraction of the waste materials (e.g., metal, ceramic).	The topography of the old burning grounds slopes down towards the northern end of Duck Pond. The absence of vegetation creates conditions where stormwater runoff and overland flow can erode surface soil and associated constituents (i.e., metals, PAHs, E&E) into the sediment at the northern end of Duck Pond. Duck Pond bathymetry confirms that deposition is greatest along the northern shoreline adjacent to the burning grounds. Infiltration of precipitation and runoff do not appear to influence local groundwater quality based on recent groundwater quality monitoring results.	The presumptive remedy involves a combination of debris/hot spot removal, and isolation and capping of the remaining material. Given the low-lying topography of the area and proximity to Duck Pond, this area may serve as a consolidation site in the event that sediment is removed from Duck Pond or for similar materials generated elsewhere onsite during remedial activities (e.g., Ammonium Nitrate Area – Former Burning Ground soil).

Table 2-1 - Areas of Presumed Remedial Action
Ecological Risk Assessment
Kenvil Works Facility
Kenvil, New Jersey

	Area of Presumed Remedial Action	History	Fate and Transport	Remedial Objective
Tier III	Storage Area – Disposal Area (N6-1)	This area served as a disposal area for solid waste materials during the period of increased production associated with WWI and the years that followed. Over time, soil has been placed/accumulated at the ground surface and the area has almost entirely revegetated with grasses and shrubs. Miscellaneous debris is present at ground surface in places. A focused removal of large metal debris occurred concurrent with Facility demolition.	This area lies at a topographic high spot onsite, well above the underlying groundwater table. Similar to the B-Line disposal area, the buried waste consists primary of solid, metal containers and similar scrap material. Constituents in soil do not appear mobile and may be related more to the fill material place atop the debris than the debris itself. The area is heavily vegetated, reducing the liklihood of erosion or wind scour of surface soil. Soil and associated constituents in this area appear stable and generally immobile.	Hercules will address the removal and/or containment of these materials during the feasibility study (FS) process. Additional evaluation and assessment of this area may be required to select an appropriate remedy.
	B Line Area - South (conglomerate of adjacent areas of concern)	Various process buildings and structures (e.g., basins, sheds) existed at the southern end of the B-Line Area near the terminus of Powder Mill Road. During decommissioning and demolition activities, residual product was observed in soil at various locations in this area and interim remedial measures (e.g., excavation) implemented. A review of SI/RI sample results identified an aggregation of locations surrounding former structures that share similar Facility-related influences approximately 11 acres in size.	This area does not occur in proximity to surface water features, and constituents detected in this area (i.e., metals and PAHs) do not appear to be influencing groundwater quality. Localized erosion and transport of surface soil and associated constituents may occur, however, the dense vegetation established in this area likely minimizes those influences. Soil and associated constituents in this area appear stable and generally immobile.	Hercules will address removal and/or containment these materials during the FS process. Additional evaluation and assessment of this area is required to refine the extente of Facility-related influences and select an appropriate remedy (where applicable).
	A Line Area - Northwest (conglomerate of adjacent areas of concern)	Historical records indicate that two buildings in the northwestern corner of the A-Line Area were destroyed during a fire and explosion. The buildings were later rebuilt on the Facility of the incident. During the SI/RI investigation and decommissioning and demolition activities, evidence of explosions (e.g., physical debris and residual source material) were identified in the area surrounding the former building locations. A review of SI/RI sample results identified two areas where these historical influences were evident.	This portion of the former operational area is relatively flat and well vegetated. Historical influences occur primarily in surface soil, and do not appear mobile in groundwater based on recent groundwater quality data. The dense vegetation throughout the area preclude erosion or wind scour of surface soils. Soil and associated constituents in this area appear stable and generally immobile.	Hercules will address the removal and/or containment of these materials during the FS process. Additional evaluation and assessment of this area is required to refine the extente of Facility-related influences and select an appropriate remedy (where applicable).
Tier IV	Development Area - Ballistics Range	The Ballistics Range tested propellant (i.e., smokeless powder) formulations to achieve manufacturer-specified projectile velocities, resulting in the introduction of lead shot and bullets to surface soil in discrete areas. During test firing on the range, projectiles impacted a backstop constructed of timber and sand. Historic fill material, imported to reclaim low-lying land during Facility expansion, underlies much of the Development Area, including the Ballistics Range. The SI/RI activities within the Ballistics Range identified metals, PAHs, SVOCs, and E&Es at concentrations exceeding NJDEP SRS.	A toxicological profile of lead completed by the Agency for Toxic Substances and Disease Registry (ATSDR 2007) found that at approximately neutral pH, lead predominately binds to carbon forming organic carbon-lead complexes. This form of lead is not bioavailable if consumed by ecological receptors. Most lead is retained strongly in soil, and very little is transported through runoff to surface water or leaching to groundwater except under acidic conditions. Based on the sources and release mechanisms, the location of lead detected in soil during SI/RI sampling, and evidence observed in the field during the Terrestrial Lead Work Plan (TLWP), lead appears to be present in surface soil as a solid debris (e.g., projectile fragments).	Hercules will remove and dispose of stockpiled lead debris and comingled surface soil in the Ballistics Range to address lead sources and residual debris material. These activities will coincidentally address areas of PAH enrichment indicative of operational influences beyond the PAH concentrations present in historic fill materials.

Table 2-1 - Areas of Presumed Remedial Action
Ecological Risk Assessment
Kenvil Works Facility
Kenvil, New Jersey

	Area of Presumed Remedial Action	History	Fate and Transport	Remedial Objective
Tier IV	Development Area - Experimental Dynamite Area	Established in 1915, the Development Area housed research and quality control activities related to the development and improvement of propellants and explosives produced onsite. The Experimental Dynamite Production Area (EDPA) produced and tested formulations of dynamite within the Development Area. NG, a component of dynamite, was manufactured in the NG Area and transported in small batches to the EDPA. EDPA structures supporting formulation and mixing of dynamite were known to have lead floors, conveyances and equipment	Lead in this area has likely remained in solid form (i.e., lead sheeting in surface soil). Neither historical processes nor current conditions are expected to influence the form or solubility of lead in surface soil. Soil and associated constituents in this area appear stable and generally immobile.	Hercules will remove and dispose of stockpiled lead debris and comingled surface soil in the EDPA to address lead sources and residual debris material.
	PETN/NG - Acid Recovery (conglomerate of adjacent areas of concern)	The Facility manufactured NG in the NG Area from site development in 1871 through Facility closure in 1996. Given NG's sensitivity to static electrical charges, building floors, process equipment and conveyances were typically lined with or constructed of lead. Prior to the 1920s, the Facility generated spent acids during the nitration process, which were then discharged to the Facility's surface water bodies via ditches and culverts. These spent acids likely contained lead derived from contact with process vessels and conveyances. Process upsets likely released these acids to the ground surface in areas outside discharge conveyances. Following the 1920s, a method was developed to recover and process these spent acids, and they were no longer discharged as a waste. Dismantlement and reconstruction of the production line in the NG Area also introduced lead into the environment.	Lead exists in in both solid and potentially dissolved forms, as a result of facility operations. The mobility of lead increases in environments with a low pH due to the enhanced solubility of lead under acidic conditions . Until the late 1800s there was not an established method to recover spent acids from nitrating explosive and energetic constituents. Following the late 1800s an economical method of recovering spent acids was developed and they were no longer considered a waste material. The use of concentrated nitric and sulfuric acid would have slowly eroded (via dissolution) lead equipment and materials, resulting in a spent acid solution containing dissolved lead. Over time, accidental discharges of acid solutions likely contributed to mobilizing lead from solid forms located in surface soil, as well as the transport of dissolved lead from the process stream to the environment. Additionally, acid releases reduced soil pH creating conditions under which lead in solid forms would more readily move into solution. These source – release mechanism combinations may have introduced lead into soil in both a solid, relatively immobile form (lead sheeting), or as more mobile lead particulates entrained in spent acid.	Hercules anticipates focused removal and/or stabilization of lead in soil in the NG Area. Remediation strategy for the remaining constituents will be aligned with redevelopment planning and addressed accordingly (if outside the redevelopment footprint).
	Maintenance Area PCBs	The Maintenance Area-Acid Production Plan was historically utilized to provide operational support including power generation and maintenance shops to the entire Facility. Historical uses of PCBs at the Facility were limited to dielectric fluids contained in electrical transformers and equipment. Wide-spread PCB detections in soil were identified throughout an approximately 13-acre area withing the Maintenance Area.	This area occurs in an area of relatively flat topography at the geographic center of the Facility. Source material (PCB concentrations greater than 10 mg/kg) has been removed, and remaining concentrations do not appear mobile based on recent groundwater quality data. Soil and associated constituents in this area appear stable and generally immobile.	Hercules has removed and disposed of soil containing PCB concentrations greater than 10 mg/kg. Remaining soil containing PCBs has been delineated and will be capped in the context of future Facility redevelopment.

Table 2-1 - Areas of Presumed Remedial Action
Ecological Risk Assessment
Kenvil Works Facility
Kenvil, New Jersey

Area of Presumed Remedial Action	History	Fate and Transport	Remedial Objective
Maintenance Area - Acid Production Plant	The Maintenance Area – Acid Production Plant produced sulfuric and nitric acids used to support various manufacturing processes onsite, as well as supply other nearby manufacturing installations.	Lead debris was not observed on the ground surface during the TLWP activities, indicating that lead likely occurs in a fine particulate or dissolved form. At low pH, dissolved lead in ions and ion pairs were the predominant species identified, and the mobility of lead increases in environments with low pH due to the enhanced solubility of lead under acidic conditions. Lead could be transported through runoff to surface water or leaching to groundwater under acidic conditions. Despite this, dissolved lead has been detected at concentrations less than the NJDEP grounwater quality standards in downgradient groundwater monitoring wells.	The remedial approach for this area will include confirmation and delineation sample to refine the nature and extent of lead in soil and sediment. Source material will then be removed and sent offsite for disposal and remaining soil will be stabilized.
NG Area - Former Ponds (TNT Ponds)	The TNT Ponds are remnant stormwater management features that occupy an area at the base of the hillside on which the NG and PETN production lines sat.	Historical surface water management practices involved the collection and channelization of water, which flowed naturally from the PETN/NG Area hillside to the base of the hill. A series of depressions (unknown origin) exist at the base of the hill into the Formet TNT Ponds. Lead particulates present in surface soil and mobilized as suspended solids may have settled out and accumulated in these depressions. These source – release mechanism combinations may have introduced lead into soil in both a solid, relatively immobile form (lead sheeting), or as more mobile lead particulates entrained in spent acid.	The remedial approach for this area will include confirmation and delineation sample to refine the nature and extent of lead in soil and sediment. Source material will then be removed and sent offsite for disposal and remaining soil will be stabilized.

Notes:

[1] Species observations made during July 2010 and July 2011 habitat characterizations.

X* = Dominant species

USFWS = United States Fish and Wildlife Service

The following are the USFWS hydrophytic classifications for the observed species:

OBL = a plant species generally (>99% of the time) only found in wetlands under natural conditions

FACW = a plant species usually (>66% to 99% of the time) found in wetlands, but which may be found occasionally in uplands under natural conditions

Note: a negative sign (-) indicates a species less frequently found in wetlands, a positive sign (+) indicates a species more frequently found in wetlands, and a star sign (*) indicates a tentative status.

FAC = a plant species sometimes (>33% to 66% of the time) found in wetlands, but which may also be found commonly in uplands

FACU = a plant species seldom (<33% of the time) found in wetlands, but which may also be found commonly in uplands

UPL = a plant species generally (>99% of the time) found only in uplands under natural conditions

NL = a plant species that is not listed

NI = insufficient information was available to determine an indicator status

NA = not available

Kenvil, New Jersey

Exposure Medium	Exposure Areas		Rationale	Receptor Group	Assessment Endpoint	Measurement Endpoint	Target Species
Soil	Terrestrial	Former Operational Areas and Undeveloped Areas	*Former Operational Areas:* Contiguous area of site that has similar historical uses and potential for operational impacts; subject to future redevelopment. *Undeveloped Areas:* Contiguous area of site that remained undeveloped during site's known history; proposed as conservation area during site redevelopment.	Terrestrial Plant Community - Structure, Function, Survival	1. Could direct contact with COPECs in site soil affect the structure, function, and/or survival of the terrestrial plant community?	1. Compare concentrations of COPECs in soil to ESBs protective of plants.	NA
				Terrestrial Invertebrate Community - Survival and Reproduction	2. Could direct contact with COPECs in site soil affect the structure, function, and/or survival of the terrestrial invertebrate community?	2. Compare concentrations of COPECs in soil to ESBs protective of terrestrial invertebrates.	NA
				Herbivorous Avian and Mammal Populations - Survival and Reproduction	3. Could food-web transfer of COPECs in site soil adversely affect reproductive success or survival of herbivorous avian and mammal populations?	3. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for herbivorous birds and mammals.	Northern Bobwhite; White-tailed Deer
				Insectivorous Avian and Mammal Populations - Survival and Reproduction	4. Could food-web transfer of COPECs in site soil adversely affect reproductive success or survival of insectivorous avian and mammal populations?	4. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for insectivorous birds and mammals.	American Robin; Short-tailed Shrew
				Carnivorous Avian and Mammal Populations - Survival and Reproduction	5. Could food-web transfer of COPECs in site soil adversely affect reproductive success or survival of carnivorous avian and mammal populations?	5. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for carnivorous birds and mammals.	Red-Tailed Hawk; Red Fox
Sediment and Surface Water	Aquatic	Northern Drainage Area (Duck Pond, miscellaneous ponds, tributaries)	*Ponds and Tributaries:* Perennial aquatic habitat features onsite, located amidst historic operational areas; miscellaneous ponds are isolated surface-water features that provide semi-aquatic habitat.	Aquatic Plant Populations - Structure, Function, Survival	6. Could direct contact with COPECs in sediment in each area affect the survival and function of aquatic plant populations?	6. Compare concentrations of COPECs in sediment and surface water in the Northern and Southern Drainage Areas to ESBs protective of terrestrial plants.	NA
				Benthic Community - Structure, Function, Survival	7. Could direct contact with COPECs in sediment in each area affect the structure, function, and/or survival of the benthic invertebrate community?	7. Compare concentrations of COPECs in sediment in the Northern and Southern Drainage Areas to ESBs protective of benthic invertebrates.	NA
				Fish and Aquatic Invertebrate Populations - Survival and Reproduction	8. Could direct contact with COPECs in surface water in each area affect the survival and reproduction of fish and aquatic invertebrate populations?	8. Compare concentrations of COPECs in surface water in the Northern and Southern Drainage Areas to ESBs protective of fish and aquatic invertebrates.	NA
				Herbivorous Avian and Mammal Populations - Survival and Reproduction	9. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of herbivorous avian and mammal populations?	9. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for herbivorous birds and mammals in the Northern and Southern Drainage Areas.	Mallard Duck; Muskrat
		Southern Drainage Area (drainage areas and wetland complex)	*Drainage Areas and Wetland Complex:* Linear intermittent drainage features drain historic operational areas to the undeveloped wetland complex, which consists of perennial aquatic habitat consisting of both flowing and non-flowing water bodies.	Insectivorous Avian and Mammal Populations - Survival and Reproduction	10. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of insectivorous avian and mammal populations?	10. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for insectivorous birds and mammals in the Northern and Southern Drainage Areas.	Tree Swallow; Little Brown Bat
				Piscivorous Avian and Mammal Populations - Survival and Reproduction	11. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of piscivorous avian and mammal populations?	11. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for piscivorous birds and mammals in the Northern and Southern Drainage Areas.	Great Blue Heron; Mink

Notes:
COPEC = constituent of potential ecological concern
ESB = ecological screening benchmark
HQ = hazard quotient
NA = not applicable
TRV = toxicity reference value

Notes:
1. New Jersey Department of Environmental Protection (NJDEP) value from Ecological Screening Criteria (ESC) Table (NJDEP 2009
2. Resource Conservation and Recovery Act Region 5 Ecological Screening Level (United States Environmental Protection Agency [U
3. Ecological Soil Screening Value (EcoSSL) (USEPA 2007)
4. Kuperman et al. 2009. In Ecotoxicology of Explosives. Sunahara et al. (eds). CRC Press.
6. Talmage et al. 1999
7. NJDEP Lowest Effects Level value
8. NJDEP Severe Effects Level value
9. Region 3 Biological Technical Assistance Group Freshwater Sediment Screening Benchmarks (USEPA 2006)
10. Verbruggen et al. 2001
11. Pascoe et al. 2010
12. Some constituents were analyzed under multiple analytical methods but are presented once in the table.
13. Metals screening values based on average hardness of 57 milligrams per liter (mg/L) calcium carbonate ($CaCO_3$) in Northern Drain and 120 mg/L CaCO3 in Southern Drainage Area. Values for the Northern Drainage Area designated with an "n" while values for th Southern Drainage Area are designated with an "s"
14. Value calculated as a function of pH based on NJDEP ESC Table.
15. Analyte detected fewer than five times and screens out based on frequency of detection. Screening value not necessary.
16. Schafer et al. 1985
17. Value for nitrobenzene used as a surrogate.
18. Conservative high molecular weight polycyclic aromatic hydrocarbons from EcoSSL Table.
19. Analyte considered an essential nutrient; therefore, a screening level is not necessary.
20. Value for nitroglycerin used as a surrogate.
21. Value for 2-amino-4,6-dinitrotoluene used as a surrogate.
22. Value for benzo(b)fluoranthene used as a surrogate.
23. Mattice et al. 1981
24. Dhawan et al. 1999
25. Value for 2-methylnaphthalene used as a surrogate.
26. Screening value is organic carbon normalized. Converted to site-specific screening value based on an average organic carbon of 13.3% in the Northern Drainage Area and 5.8% in the Southern Drainage Area.
27. Value for saline water in the NJDEP ESC Table used for lack of a freshwater value.
28. Sediment value from NOAA Screening Quick Reference Tables (SQuiRTs).
29. Department of Defense. 1980. Data Summary for Nitrocellulose.

-- = not applicable
CAS = Chemical Abstract Service
mg/kg = milligram per kilogram

Notes:
1. Considered bioaccumulative according to USEPA 2000 and NJDEP 2015
2. Although not considered bioaccumulative, explosive compounds were included in the dose-exposure model based on their direct ties to the site operational histor

% = percent
COPEC = constituent of potential ecological concern
mg/kg = milligram per kilogram
ug/kg = microgram per kilogram
PCB = polychlorinated biphenyl
SVOC = semivolatile organic compound
VOC = volatile organic compound
-- = no sediment ESB available

Notes:
Bolded values indicate a hazard quotient that is greater than 1
COPEC = constituent of potential ecological concern
HQ = hazard quotient
ESB = ecological screening benchmark
Y = yes
N = no
ug/L = micrograms per liter
mg/L = milligram per liter
VOCs = volatile organic compounds
SVOCs = semivolatile organic compounds
Screening Criteria from Ecological Screening Benchmark (ESB) Table 4-2
* only totals metal data available; screen based on total metals in this case
In cases where an ESB is only available for total metals, the dissolved metal data is screened against the total metal ESB

Notes:

Bolded values indicate a hazard quotient that is greater than 1
COPEC = constituent of potential ecological concern
LEL - lowest effects level
SEL = severe effects level
HQ = hazard quotient
ESB = ecological screening benchmark
Sed N = sediment Northen drainage area
Y = yes
N = no
ug/kg = micrograms per kilogram
mg/kg = milligram per kilogram
VOCs = volatile organic compounds
SVOCs = semivolatile organic compounds

Notes:
Bolded values indicate a hazard quotient that is greater than 1
COPEC = constituent of potential ecological concern
LEL - lowest effects level
SEL = severe effects level
HQ = hazard quotient
ESB = ecological screening benchmark
Sed S = sediment Southern drainage area
Y = yes
N = no
ug/kg = micrograms per kilogram
mg/kg = milligram per kilogram
VOCs = volatile organic compounds
SVOCs = semivolatile organic compounds

Notes:

1. EPC = 95UCL when available (i.e., sample size greater than or equal to 8 with a minimum of 5 detections and a discernable distribution).
2. The exposure point concentration is the 95UCL when available (i.e., sample size greater than or equal to 8 with a minimum of 5 detections).
3. Considered bioaccumulative according to USEPA 2000 and NJDEP 2015. (X indicates that the chemical is bioaccumulative)
4. Although not considered bioaccumulative, explosive compounds were included in the dose-exposure model based on their direct ties to the site operational history.

95UCL = 95% upper confidence limit of the mean
COPEC = constituent of potential ecological concern
HQ = hazard quotient
ESB = ecological screening benchmark
EPC = exposure point concentration (if mean > 95UCL, mean was used. If 95UCL couldnt be calculated, max detection was used.)
Y = yes
N = no
FOD = frequency of detection
mg/kg = milligram per kilogram
ug/kg = microgram per kilogram
PCB = polychlorinated biphenyl
SVOC = semivolatile organic compound
VOC = volatile organic compound
HMX = Octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine
LOAEL = lowest observed adverse effects level
NOAEL = no observed adverse effects level
NA = not analyzed

Notes:

1. EPC = 95UCL when available (i.e., sample size greater than or equal to 8 with a minimum of 5 detections and a discernable distribution).
2. Sediment chemistry evaluation includes background threshold comparison for arsenic and a study comparison for mercury
3. Bioavailability/toxicity evaluation includes AVS/SEM for metals and Equilibrium Partitioning for PAHs
4. Onsite benthic community sampling includes both flowing and non-flowing aquatic high gradient benthic index, and Shannon-Weiner Diversity Indices and Abundance; this evaluation method is weighted more heavily than the sediment chemistry and bioavailability/toxicity, as the data are from site specific (SS) sources

Bolded values indicate a hazard quotient that is greater than 1
Gray shaded rows indicate acceptable risk for that specific evaluation method

Definitions:

COPEC = constituent of potential ecological concern
UCL = upper confidence level
HQ = hazard quotient
ESB = ecological screening benchmark
Sed N = sediment Northen drainage area
EPC = exposure point concentration (if mean > 95UCL, mean was used. If 95UCL couldnt be calculated, max detection was used.)
Sed S = sediment Southern drainage area
Y = yes
N = no
ug/kg = micrograms per kilogram
mg/kg = milligram per kilogram
FOD = frequency of detection
VOCs = volatile organic compounds
SVOCs = semivolatile organic compounds
LOAEL = lowest observed adverse effects level
NOAEL = no observed adverse effects level
NA = not analyzed
+ = potential unacceptable risk; not screened out by benthic invertebrate additional risk evaluation analysis method
- = acceptable risk; screened out by benthic invertebrate additional risk evaluation analysis method

Notes:

1. EPC = 95UCL when available (i.e., sample size greater than or equal to 8 with a minimum of 5 detections and a discernable distribution).
2. The exposure point concentration is the 95UCL when available (i.e., sample size greater than or equal to 8 with a minimum of 5 detections).
3. Considered bioaccumulative according to USEPA 2000 and NJDEP 2015. (X indicates that the chemical is bioaccumulative)
4. Although not considered bioaccumulative, explosive compounds were included in the dose-exposure model based on their direct ties to the site operational history.

95UCL = 95% upper confidence limit of the mean
COPEC = constituent of potential ecological concern
HQ = hazard quotient
ESB = ecological screening benchmark
EPC = exposure point concentration (if mean > 95UCL, mean was used. If 95UCL couldnt be calculated, max detection was used.)
Y = yes
N = no
FOD = frequency of detection
mg/kg = milligram per kilogram
ug/kg = microgram per kilogram
PCB = polychlorinated biphenyl
SVOC = semivolatile organic compound
VOC = volatile organic compound
HMX = Octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine
LOAEL = lowest observed adverse effects level
NOAEL = no observed adverse effects level
NA = not analyzed
HMX = Octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine
* only totals metal data available; screen based on total metals in this case
In cases where an ESB is only available for total metals, the dissolved metal data is screened against the total metal ESB

Notes:

1. 95UCLs calculated using ProUCL v5.2 including non-detect values and at a 95% confidence level (α = 0.05). Datasets all had a sample size greater than or equal to 8 and detects greater than or equal to 5. The average of the detected constituents or the minimum detection limit was selected for duplicate samples.
2. The exposure point concentration is the 95UCL when available (i.e., sample size greater than or equal to 8 with a minimum of 5 detections).
3. Considered bioaccumulative according to USEPA 2000 and NJDEP 2015.
4. Although not considered bioaccumulative, explosive compounds were included in the dose-exposure model based on their direct ties to the site operational history.

% = percent
95UCL = 95% upper confidence limit of the mean
COPEC = constituent of potential ecological concern
mg/kg = milligram per kilogram
ug/kg = microgram per kilogram
PCB = polychlorinated biphenyl
SVOC = semivolatile organic compound
VOC = volatile organic compound
-- = no sediment ESB available

Notes:
Bolded values indicate a hazard quotient that is greater than 1
COPEC = constituent of potential ecological concern
UCL = upper confidence level
HQ = hazard quotient
ESB = ecological screening benchmark
Y = yes
N = no
ug/L = micrograms per liter
mg/L = milligram per liter
FOD = frequency of detection
VOCs = volatile organic compounds
SVOCs = semivolatile organic compounds
Screening Criteria from Ecological Screening Benchmark (ESB) Table 4-2
* only totals metal data available; screen based on total metals in this case
In cases where an ESB is only available for total metals, the dissolved metal data is screened against the total metal ESB

Notes:

*The exposure point concentration is the 95UCL when available (i.e., sample size greater than or equal to 8 with a minimum of 5 detections and a discernable distribution).

Bolded values indicate a hazard quotient that is greater than 1

COPEC = constituent of potential ecological concern

LEL - lowest effects level

SEL = severe effects level

UCL = upper confidence level

HQ = hazard quotient

ESB = ecological screening benchmark

Sed N = sediment Northen drainage area

EPC = exposure point concentration (if the mean was greater than the 95UCL, the mean was used. If no 95UCL could be calculated, then the max detection was used.)

Y = yes

N = no

ug/kg = micrograms per kilogram

mg/kg = milligram per kilogram

FOD = frequency of detection

VOCs = volatile organic compounds

SVOCs = semivolatile organic compounds

Notes:

*The exposure point concentration is the 95UCL when available (i.e., sample size greater than or equal to 8 with a minimum of 5 detections and a discernable distribution).

Bolded values indicate a hazard quotient that is greater than 1

COPEC = constituent of potential ecological concern

LEL - lowest effects level

SEL = severe effects level

UCL = upper confidence level

HQ = hazard quotient

ESB = ecological screening benchmark

EPC = exposure point concentration (if the mean was greater than the 95UCL, the mean was used. If no 95UCL could be calculated, then the max detection was used.)

Sed S = sediment Southern drainage area

Y = yes

N = no

ug/kg = micrograms per kilogram

mg/kg = milligram per kilogram

FOD = frequency of detection

VOCs = volatile organic compounds

SVOCs = semivolatile organic compounds

Notes:

a. Nagy 2001

b. USEPA 1993

c. Daily ingestion rates converted to dry weight assuming a moisture content of the following (USEPA 2007):
Invertebrates: 84%
Tissue: 68%
Plants: 85%

d. Beyer et al. 1994 (muskrat based on values for woodchuck; robin based on values for woodcock; bobwhite based on values for wild turkey)

e. USEPA 2007

f. Conservative estimates

g. Aerial insectivore; therefore, soil/sediment ingestion assumed to be neglible (Sample and Suter 1994).

h. Calculated by multiplying the soil ingestion rate times the dry weight daily ingestion rate.

i. Calculated using the allometric equation for non-passerines from USEPA 1993.

% = percent

kg = kilogram

kg/day dw = kilogram per day dry weight

kg/day ww = kilogram per day wet weight

USEPA = United States Environmental Protection Agency

Notes:

a. Ecological soil screening levels (EcoSSLs) (2003-2008). EcoSSLs identify the NOAEL; the is from either the corresponding study, or is extrapolated from the NOAEL using a multiplying facto of 10. USEPA did not identify a TRV for PAHs for birds; therefore, the lowest reported effect level from the studies assigned an Evaluation Score greater than 10 was used.

b. Sample et al. 1996

c. United States Army Center for Health Promotion and Preventative Medicine

-- = not applicable

COPEC = constituent of potential ecological concern

Notes:

*The exposure point concentration is the 95UCL when available (i.e., sample size greater than or equal to 8 with a minimum of 5 detections and a discernable distribution).

Bolded values indicate a hazard quotient that is greater than 1

COPEC = constituent of potential ecological concern

UCL = upper confidence level

HQ = hazard quotient

ESB = ecological screening benchmark

Sed N = sediment Northen drainage area

EPC = exposure point concentration (if the mean was greater than the 95UCL, the mean was used. If no 95UCL could be calculated, then the max detection was used.)

Y = yes

N = no

ug/kg = micrograms per kilogram

mg/kg = milligram per kilogram

VOCs = volatile organic compounds

SVOCs = semivolatile organic compounds

Notes:

Bolded values indicate a hazard quotient based on the 95UCL that is greater than 1.

a. Value for chrysene (HMW PAH) used as surrogate.

b. Efroymson et al. 1997b

c. Ecotox database (value is NOAEL for black poplar [*Populus nigra*] from Wittig et al. 2003).

d. Sverdrup et al. 2003

e. Ecological soil screening levels

-- = dataset too small to calculate 95UCL

95UCL = 95th percentile upper confidence limit of the mean

COPEC = constituent of potential ecological concern

HMW = high molecular weight

mg/kg = milligram per kilogram

µg/kg = micrograms per kilogram

NA = not available

SVOC = semivolatile organic compound

Notes:
Bolded values indicate a hazard quotient that is greater than 1
COPEC = constituent of potential ecological concern
UCL = upper confidence level
HQ = hazard quotient
ESB = ecological screening benchmark
Y = yes
N = no
ug/L = micrograms per liter
mg/L = milligram per liter
FOD = frequency of detection
VOCs = volatile organic compounds
SVOCs = semivolatile organic compounds
Screening Criteria from Ecological Screening Benchmark (ESB) Table 4-2
* only totals metal data available; screen based on total metals in this case
In cases where an ESB is only available for total metals, the dissolved metal data is screened against the total metal ESB

Notes:
Bolded values indicate a hazard quotient that is greater than 1.
C = concentration
COPEC = constituent of potential ecological concern
EPC = exposure point concentration
HQ = hazard quotient
kg = kilogram
kg/day = kilogram per day
LOAEL = lowest observed adverse effects level
mg/kg = milligram per kilogram
mg/kg/d = milligram per kilogram per day
NOAEL = no observed adverse effects level
NA = not available
TRV = toxicity reference value
AUF = area use factor

Notes:

*The exposure point concentration is the 95UCL when available (i.e., sample size greater than or equal to 8 with a minimum of 5 detections and a discernable distribution).

Bolded values indicate a hazard quotient that is greater than 1

COPEC = constituent of potential ecological concern

UCL = upper confidence level

HQ = hazard quotient

ESB = ecological screening benchmark

EPC = exposure point concentration (if the mean was greater than the 95UCL, the mean was used. If no 95UCL could be calculated, then the max detection was used.)

Sed S = sediment Southern drainage area

Y = yes

N = no

ug/kg = micrograms per kilogram

mg/kg = milligram per kilogram

VOCs = volatile organic compounds

SVOCs = semivolatile organic compounds

Table 7-20
Hazard Quotients for Aquatic Plants - Southern Subdrainage Areas
Ecological Risk Assessment
Kenvil Works Facility
Kenvil, New Jersey

COPEC	Units	Screening Value	Note	Exposure Point Concentration		Hazard Quotients	
				Maximum Detected	95UCL	Maximum Detected	95UCL
SVOCs							
Benzo(g,h,i)perylene	µg/kg	10	a	610	346.2	61	**35**
Dibenzo(a,h)anthracene	µg/kg	10	a	290	--	29	**--**
Pyrene	µg/kg	56	e	1300	840	23	**15**

Notes:
Bolded values indicate a hazard quotient based on the 95UCL that is greater than 1.
a. Value for chrysene (HMW PAH) used as surrogate.
b. Efroymson et al. 1997b
c. Value for di-n-butylphthalate used as a surrogate.
d. Ecotox database (value is NOAEL for black poplar [*Populus nigra*] from Wittig et al. 2003).
e. Sverdrup et al. 2003
f. Ecological soil screening levels
g. Sunahara et al. 2009 (Table 12.5 for weathered and aged)
h. Value for acenaphthene used as surrogate
i. Value for TNT used as surrogate (Talmage et al. 1999)
-- = dataset too small to calculate 95UCL
95UCL = 95th percentile upper confidence limit of the mean
COPEC = constituent of potential ecological concern
HMW = high molecular weight
mg/kg = milligram per kilogram
NA = not available
SVOC = semivolatile organic compound

Notes:
Bolded values indicate a hazard quotient that is greater than 1
COPEC = constituent of potential ecological concern
UCL = upper confidence level
HQ = hazard quotient
ESB = ecological screening benchmark
Y = yes
N = no
ug/L = micrograms per liter
mg/L = milligram per liter
FOD = frequency of detection
VOCs = volatile organic compounds
SVOCs = semivolatile organic compounds
Screening Criteria from Ecological Screening Benchmark (ESB) Table 4-2
* only totals metal data available; screen based on total metals in this case
In cases where an ESB is only available for total metals, the dissolved metal data is screened against the total metal ESB
** no COPECs moved on to the fish HQ screen

Notes:
Bolded values indicate a hazard quotient that is greater than 1.
*invertebrate concentration from onsite aerial insect tissue sampling max concentration identified in the southern drainage area
a. Aerial insect tissue in the subdrainage area was all non-detect for this constituent; highest reporting limit was used
b. No aerial insect tissue was collected for this constituent in this subdrainage area; BSAFs used instead

AUF = area use factor
C = concentration
COPEC = constituent of potential ecological concern
EPC = exposure point concentration
HQ = hazard quotient
kg = kilogram
kg/day = kilogram per day
LOAEL = lowest observed adverse effects level
mg/kg = milligram per kilogram
mg/kg/d = milligram per kilogram per day
NA = not available
NOAEL = no observed adverse effects level
TRV = toxicity reference value

Notes:

Bolded values indicate a hazard quotient that is greater than 1.

*invertebrate concentration from onsite aerial insect tissue sampling max concentration identified in the southern drainage area

a. Aerial insect tissue in the subdrainage area was all non-detect for this constituent; highest reporting limit was used

b. No aerial insect tissue was collected for this constituent in this subdrainage area; BSAFs used instead

AUF = area use factor

C = concentration

COPEC = constituent of potential ecological concern

EPC = exposure point concentration

HQ = hazard quotient

kg = kilogram

kg/day = kilogram per day

LOAEL = lowest observed adverse effects level

mg/kg = milligram per kilogram

mg/kg/d = milligram per kilogram per day

NA = not available

NOAEL = no observed adverse effects level

TRV = toxicity reference value

NJDEP's 8 July 2019 Comments & Hercules' Response Matrix

Comment Number	Report Section	Comment	Resolution
General Comment A:	The EE/ERA (RIR Volume F) takes a facility-wide approach in its evaluation of potential COPEC impacts to terrestrial (Section 3.3.3.1, page 31 and Figure 3-2, e-page 215) and aquatic (Section 3.3.3.2, page 32 and Figure 3-3, e-page 216) receptors. This approach does not consider (a) the size of specific habitat patches on the site relative to the home ranges of the receptor species using those patches, (b) specific Environmentally Sensitive Natural Resources (ESNRs) with elevated COPEC (greater than the 95UCL) concentrations, and (c) other specific areas with elevated COPEC concentrations (greater than the 95UCL) that could potentially impact ESNRs. To evaluate the appropriateness of this approach, please note the following comments –		The updated ERA reflects additional work done following submission of the 2016 EE/ERA to refine the risk characterization in specific terrestrial and aquatic habitats. Consistent with NJDEP's July 2019 comments, this work included breaking down the aquatic drainage areas into subdrainage areas (**Section 3.2.4.2 & Attachment 10 –** Aquatic ERA Supplemental Sampling Memorandum), and refining terrestrial area risk estimates via the identification of areas (**Attachment 8** – Terrestrial Lead Work Plan). The updated ERA also refines the exposure areas and area use factors such that upper trophic level models account for home range size, migratory patterns, and habitat preferences (**Section 5.1.2**). **Section 5.1.1.1.1.2** introduces spatial weighting and surface-area weighted average concentrations for certain COPECs to identify samples or clusters of samples with the potential to drive risk at a localized level (including in or proximate to ESNRs), recommendations for additional ERA activities presented in **Section 9.2** build upon this approach. The updated ERA assesses risk across the same geographic footprint as the 2016 EE/ERA, and identifies areas of habitat that meet the definition of ESNRs within the exposure areas. Where appropriate, interpretation of HQs and recommended activities consider habitat quality, ESNR status, and the potential presence of T&E species.
1		The EE/ERA (RIR Volume F) and the RIR Summary (Volume A) do not identify and discuss potential impacts to specific Environmentally Sensitive Natural Resources (ESNRs) on and adjacent to the site as required by NJAC 7:26E-1.16(a), and as specified in Section 5.2.1 of the NJDEP Site Remediation and Waste Management Program Ecological Evaluation Technical Guidance (EETG; Version 2.0, August 2018). RIR Summary (Volume A) Figure A-6 (e-page 101) and RIR Volume F (EE/ERA) Figure 2-2 (e-page 213) provide mapping of selected types of habitat present on the site (including forest, wetlands, and aquatic areas – but not vernal pools). However, RIR Summary (Volume A) Section 2.3.2 (page 2-4) provides a very cursory overview (or none at all) of these habitats; RIR Volume F (EE/ERA) Section 2.6 (and sub-sections; pages 10-15) describes various types of terrestrial, aquatic, and wetlands habitats on the site but does not identify specific ESNRs. RIR Volume F (EE/ERA) Section 2.5 (page 9) discusses the presence of State and federal Threatened and Endangered (T/E) species on the site and states that "[n]one of the T & E species listed as possibly present on or near the Facility have been identified onsite[sic]". However, potential habitat for bog turtle (*Glyptemys muhlenbergii)* has been identified on-site, and species-specific surveys for other T/E species that may be present on the site have apparently not been conducted.	The updated ERA identifies specific ESNRs and migration pathways from general habitat areas to ESNRs as part of conceptual site model (**Section 3.2**). The ERAWP included as an appendix to the 2016 EE/ERA separated the two large aquatic drainage areas into 13 subdrainage areas. The updated ERA identifies these subdrainage areas as specific ESNRs (e.g., surface waters, wetlands), and evaluates risk considering the sensitivity of these habitats and the potential receptors using them. Facility conditions do not influence areas offsite (ESNRs or otherwise). The results of the 2017 Phase I Bog Turtle Habitat Assessment are incorporated into the wetland resource value classification established by NJDEP and inform the identification of ESNRs in the updated ERA (**Section 3.2.1.3.1**).

Comment Number	Report Section	Comment	Resolution
2	RIR Volume F (EE/ERA) Section 3.3.3.1 (page 31):	states the "formerly developed portion of the Facility (the Remedial Area) provides patches of habitat for ecological receptors. Upper-trophic-level [sic] ecological receptors using onsite [sic] terrestrial habitats are likely to move among the habitat patches that share a common list of Facility-related constituents, as well as similarities in habitat type and composition". However, it could be expected that the distribution of lower trophic level receptors/prey would be limited to smaller habitat patches with a variety and range of COPEC concentrations (potentially including concentrations greater than the 95UCL).	**Section 5.1.1.1.1.2** introduces spatial weighting and surface-area weighted average concentrations for certain COPECs to identify samples or clusters of samples with the potential to exceed the 95UCL at a localized level, recommendations for additional ERA activities presented in **Section 9.2** build upon this approach. Please see the discussion of home ranges and area use factors above. The estimation of prey item concentrations across upper trophic level receptor home ranges is discussed in the Updated ERA (**Section 5.1.2.1.6**).
3	RIR Summary (Volume A) Section 4.2.2 (page 4-8):	notes that "natural succession of flora and fauna growth has been allowed to progress uninhibited with vegetative communities expanding" since the completion of facility demolition activities in 2003. RIR Summary (Volume A) Section 5.3.3 (page 5-17) further states that the "combination of increased habitat and decreased activity and disturbance likely increased the number and variety of ecological receptors using the Facility". It appears that field surveys of the site were last conducted in July 2010 and May-July 2011 (RIR Volume F [EE/ERA] Section 2.6, page 10); given the age of these surveys and continuing post-demolition secondary succession occurring on-site, it may be appropriate to conduct additional surveys to develop an updated habitat characterization.	Remediation activities at the site have resulted in a near-continuous presence of staff onsite and associated habitat and wildlife observations. These qualitative observations inform receptor selection in the updated ERA. Habitat succession is ongoing, and the updated ERA incorporates updated mapping based on remote sensing data as well as field verification surveys (**Section 3.2.1**).

General Comment B:	RIR Volume F (EE/ERA) Section 3.3.4.1 (page 33) and Figure 3-2 (e-page 215) identify terrestrial "Areas of Presumed Remedial Action" (including areas where ecological risk is likely/very likely; Executive Summary, page ES-2) that have been excluded from the EE/ERA terrestrial ecological risk evaluations. However, these areas have not been otherwise so identified for remediation in the Phase II RIR. See Comments #4-#8 below – based on these conclusions and recommendations of the Phase II RIR, it appears to be premature/inappropriate for the EE/ERA to identify terrestrial "Areas of Presumed Remedial Action". Further, such a designation appears to potentially pre-judge future decisions regarding the need to conduct remedial activities on the site.		Please refer to **Section 3.4.1, Appendix B, and Attachment 2** Hercules is committed to active remediation in areas where historical operational influences have resulted in conditions that are not protective of human health and/or the environment. In the time elapsed since submission of the Phase II RIR, Hercules has initiated remedial actions in certain Areas of Presumed Remedial Action, implemented pre-design investigations that have refined the spatial extents of certain Areas of Presumed Remedial Action, and conducted ecological field studies to identify additional Areas of Presumed Remedial Action (based in part on the terrestrial risk characterization results of the ERA). The collective progress toward remediation of areas overtly influenced by historical Facility operations is summarized in the updated ERA. With regards to NJDEP comment regarding pre-judging, the identification of Areas of Presumed Remedial Action represents an initial step toward remediation and is based on field observations and the existing dataset. Consistent with NJDEP comments #4 through #8 below, Hercules anticipated completing further work to refine the extents of Facility-related influences and inform the selection and design of the most appropriate remedy for these areas. Additional information generated during these pre-design efforts will provide data at a spatial scale commensurate with the APRA being evaluated, and supplement the larger scale SI/RI dataset used to identify the APRA. Hercules recognizes that, if remedial design activities associated with an Area of Presumed Remedial Action refine its extents (possible) or demonstrates that there is not a need for an active remedy (unlikely), an ERA of that area will need to be conducted to support AOC closure (along with appropriate comparison to SRS protective of human health). Hercules also acknowledges that the list of Areas of Presumed Remedial Action represents a subset of the total area onsite requiring remediation to comply with the TRSR. Hercules intends to rely on the tiered system of prioritized action in Areas of Presumed remedial Action to guide remediation activities onsite. This system prioritizes addressing historical facility-related influences that have potential migration pathways to receptors (i.e., TNT groundwater plume migration), maintaining protection of human health and the environment as a top priority and making the most efficient use of time and resources dedicated to the remediation of the Facility.
4	RIR Volume F (EE/ERA) Section 3.3.4.1 (page 33):	prioritizes the "Areas of Presumed Remedial Action" using a tiered system "to guide the feasibility study process". This tiered system is "based (in part) on elements such as complexity of the remedy, severity of the effects, duration of remedy implementation, and/or alignment with Facility redevelopment planning". This tiered priority system, and the associated data and evaluations used to implement it, were not included in the Phase II RIR. Table 3-1 (e-page 138) of RIR Volume F (EE/ERA) summarizes the "History", "Fate and Transport", and "Remedial Objective" (including presumptive remedies, additional investigations, and the need to conduct additional evaluations during the feasibility study process) for each of the areas. RIR Volume F (EE/ERA) Section 3.2.2 (page 23) notes that "[p]re-design investigations are underway in these areas to support remedy selection and design"; also see the descriptions of these areas in RIR Volume F (EE/ERA) Appendix B, e-page 1984.	See response to General Comment above. **Appendix B** and **Attachment 2** updated the current status of the ARPAs and articulate how Hercules is approaching active remediation in support of AOC closure at the Facility. The EE/ERA is Volume F of the Phase II RIR. As such, statements and conclusions made in the EE/ERA are part of the Phase II RIR. Hercules acknowledges that the level of specificity with which the APRAs were discussed in the EE/ERA was not carried through to the Phase II RIR Summary – Volume A.

5		The Phase II RIR concludes (RIR Summary [Volume A] Section 6, page 6-1) that "refining the extent of certain constituents on an area- or constituent-specific basis is necessary to develop appropriate remedies protective of human health and the environment". Further, additional investigations are recommended that "would inform the preparation of a soil management plan and remedial action selection report (feasibility study), and ultimately remedial action design and implementation. Hercules believes a document focused on remedial action selection … represents a meaningful step in the remedy process given the scale and complexity of the Facility"	See response to General Comment above.
6	RIR Volume B (Soil) Section 6.4 (page 47):	also states "refining the extent of certain constituents on an area- or constituent-specific basis is necessary to develop appropriate remedies protective of human health and the environment". Further, "additional data should be collected as part of pre-design investigation[s] supporting the feasibility study/remedial design process, as they may reduce the footprint and/or quantity of soil subject to remediation and reduce disturbance to ecologically sensitive areas".	See response to General Comment above.
7	RIR Volume D (Sediment) Section 6.4 (page 44):	states the EE/ERA "acknowledges that remedial action is necessary in certain areas of the Facility, prioritizes these areas based on complexity and severity, and outlines presumptive remedies with each area … Hercules is committed to addressing these areas, and other areas identified via ongoing risk assessment activities. Comprehensive remedies addressing both upland source areas and related sediment influences will be developed to address protection of both human health and [the] environment".	See response to General Comment above.
8	RIR Volume E (Surface Water) Section 6.4 (page 30):	states that Hercules will (a) "[c]ollectively evaluate remedial actions related to soil and sediment to identify their influence on surface water quality and incorporate surface water quality remedial goals into the design process", and (b) "[e]valuate Facility-related influences on surface water quality that do not coincide with soil and/or sediment remedies as part of the remedial design process". Further, the "results of the EE/ERA (Volume F) will also influence remedial decision making with respect to ecological endpoints".	See response to General Comment above.
9	RIR Volume F (EE/ERA) Section 3.3.3.2, page 32 and Figure 3-3, e-page 216:	The Southern Drainage Aquatic Exposure Area includes areas/ditches along Route 46 and the southeastern boundary of the site that are outside the established Remedial Area Boundary, but "receive surface water and suspended sediment from the southern wetland complex (within the Remedial Area boundary) that drains operational areas of the Facility. These drainage channels also receive runoff from Howard Boulevard and Route 46". *Are terrestrial/upland parcels in this area also impacted by these discharges?*	Two subdrainage exposure areas (Misc. Offsite Streams – Upper and Misc. Offsite Streams – Lower) were evaluated to address the southern wetland complex. See **Sections 2.4.2**, **3.2.1.1**, & **3.2.4.2.2.** Adjacent upland areas are not influenced by the drainage channels flowing through the southern wetland complex. The flood modeling conducted in association with permitting the TNT bioremediation project resulted in a FHA boundary generally consistent with the wetland/water boundaries delineated in the 2021 Freshwater Wetlands Letter of Interpretation. See **Section 3.2** of the updated ERA.

10		A review and comparison of RIR Volume F (EE/ERA) Figure 3-2 (e-page 215) and RIR Summary (Volume A) Figure A-6 (e-page 101) indicates that the boundaries of the terrestrial "Areas of Presumed Remedial Action" include streams/ditches (particularly in the TNT Area; areas denoted "1" on EE/ERA Figure 3-2), and thus potentially riparian areas and wetlands associated with these waterbodies. Have the extent of wetlands and riparian areas on the site been verified by a NJDEP Land Use Regulation Program Letter of Interpretation? RIR Volume F (EE/ERA) Section 2.6 (page 10) notes that a Facility-wide wetlands assessment was conducted in May-July 2011. Please provide the following information concerning these "Areas of Presumed Remedial Action": (a) the basis for concluding (and prioritizing – see Comment #1 above) that remedial action is needed in these areas, (b) the status/schedule of remedial actions in these areas, (c) the type of remedial actions (to be) completed in these areas, and (d) an evaluation of the potential effects of these remedial actions to eliminate/reduce potential COPEC-related impacts to terrestrial and aquatic receptors (it appears that these areas are within/adjacent to wetlands and/or surface waterbodies).	The updated ERA incorporates delineated wetland boundaries Facility-wide established via a November 2021 FWW Letter of Interpretation, and FHA Verification information developed as part of permitting the TNT remediation project (TNT Area APRA). Hercules' December request for a remedial timeframe extension 2023 (**Attachment 2**) includes information on APRAs, including scope and anticipated schedule. This information has been incorporated into the updated ERA (**Section 3.4.1 & Appendix B**). While the need for a remedy has been identified in APRAs, in certain cases, the type of remedy has not been selected at present. The pre-design investigation and/or remedial action selection/feasibility study processes will inform definition of a remedy protective of human health and the environment that minimizes disturbances to sensitive areas (e.g., ESNRs).
General Comment C:	RIR Volume F (EE/ERA) Section 3.3.4.2 (page 34) discusses "Areas Beyond the Remedial Area Boundary", and notes that these areas were identified in the Site Investigation/Phase I RI by comparing sample results to "criteria protective of human health (i.e., soil remediation goals)". It is also stated that "sample results from the undeveloped areas around the margins of the Facility (outside the Remedial Area) were evaluated in the context of potential ecological risk". This analysis was conducted in RIR Volume F (EE/ERA) Appendix C (e-page 2133) in which the 95UCL of the mean for each COPEC was compared to ecological screening benchmarks. Those COPECs with an HQ $\geq$ 1 that also bioaccumulate were then further evaluated using a food web model to estimate potential impacts to upper trophic level species.		As indicated in **Section 9** of the updated ERA, additional data collection is ongoing in the Areas Beyond the Remedial Area Boundary exposure area, with a sampling event scheduled for Fall 2025 to complete delineation of constituents present at concentrations greater than NJDEP's migration to groundwater soil remediation standards. Following completion of delineation, the ERA of this area will be updated as follows: A), COPEC screen using the updated dataset, B) evaluating discontinuous areas as individual exposure areas (e.g., uplands along Rt 46, western ridgeline, eastern ridgeline, northern undeveloped area), C) assessing dataset composition (e.g., outliers) for each exposure area, and D) providing recommendations on an area-by-area basis to address potential ecological risks (e.g., HQ>1), if identified.
	Table C-1, e-page 2140:	A review of the soil data used in this analysis (indicates that for a number of the COPECs – particularly arsenic, beryllium, chromium, cobalt, copper, lead, manganese, nickel, selenium, zinc, and nitroglycerin – the maximum detected concentration in the soil samples is substantially greater than its 95UCL. Thus, there may be locations in the "Areas Beyond the Remedial Area Boundary" where elevated COPEC concentrations potentially result in adverse ecological impacts.	See response to General Comment C above. This specific comment will be addressed in the updated evaluation.
	RIR Volume F (EE/ERA) Appendix C, Section 3.1, page 2:	identifies seven (7) metals with 95UCL concentrations with an HQ $\geq$ 1 for potential impacts to terrestrial plants and soil invertebrates. However, the conclusions of this evaluation (Section 4, page 3) appear to disregard these results when stating that "potential ecological risks beyond the Remedial Area are unlikely".	See response to General Comment C above. This specific comment will be addressed in the updated evaluation.
	RIR Volume F (EE/ERA) Appendix C, Figure C-1 (e-page 2148):	a wetlands area in the southern portion of the site along Route 46 is included in the "Areas Beyond the Remedial Area Boundary". However, the evaluation of the soil/sediment data collected in this area did not include comparisons to the NJDEP Freshwater Sediment Ecological Screening Criteria to calculate HQs.	See response to General Comment C above. This specific comment will be addressed in the updated evaluation.

General Comment D:	Section 5.3.3.1 of the NJDEP Site Remediation and Waste Management Program Ecological Evaluation Technical Guidance (EETG; Version 2.0, August 2018) specifies that soil (and sediment) samples should be collected from the 0 to 6-inch below ground surface (bgs) depth interval (except for those to be analyzed for VOCs). A cursory review of the collected soil data (RIR Volume B [Soil] Appendix F, e-page 22028), and previous NJDEP November 18, 2010 comments on the Phase I Remedial Investigation (RI; noted below), indicate that very few of the soil samples collected during the Site Investigation (SI), Phase I RI, and Phase II RI work were collected from the 0-6 inch bgs depth interval. The requirement to collect soil (and sediment) samples at this depth interval was previously identified in the following NJDEP November 18, 2010 comments (RIR Volume A-Summary, Attachment 2, e-page 230)		Please see responses to specific comments Nos. 11 through 14 below.
11	Volume B – No. 2: Section 2.4	Soil Sampling" stated "[t]ables indicate that most surface soil samples were collected from [the 6-12 inch interval below ground surface]. This is deficient according to NJAC 7:26E-3.6(a)3 which states that initial characterization of soil samples (except VOC samples) shall be collected at 0-6 inches below grade … ";	This comment pertained to the SI and Phase I RIR soil sampling. Work plans for these efforts were approved by NJDEP and scoping and implementation of the Phase I RI was conducted in cooperation with NJDEP via the triad approach. The deficiency noted in this comment on the Phase I RIR was addressed via sampling conducted in the Phase II RI – see response to comment 14 below. Hercules also notes that the cited text comes from NJDEP's Specific Comments – Volume B – Soil - Comment No. 1 titled Section 2.4 Soil Sampling, rather than No. 2 as indicated.
12	Volume B – No.3: Section 2.4.1.3	stated that "no (0-6") [soil samples] were collected from any of the AOCs";	The referenced comment from NJDEP's 18 November 2010 comments pertains to sampling conducted at 44 areas of concern reserved for the RI during the SI phase. The decisions to reserve these areas for the RI was based on SI analytical data and/or observations indicating that soil in these AOCs would likely exceed NJDEP remediation standards and require remediation. This rationale aligns with the APRA approach used in the ERA (**Table 2-1**), as evidenced by the fact that 35 of the 44 AOCs reserved for the RI occur within APRAs. The data collected and locations assessed occur primarily within APRAs and thus have negligible influence or bias on the dataset used in the ERA. Any sampling necessary to fill data gaps in these areas will be addressed when scoping pre-design investigation activities for APRAs. The remaining nine areas occur in the central core of the Facility where redevelopment planning is occurring. Redevelopment is anticipated to address potential ecological risk by rendering exposure pathways incomplete.
13	Volume A – No. 14 - Section 8.0	Future Actions" (Bullet #3) stated that additional "surface soil sampling from the 0-6" interval from various AOCs throughout the site, particularly … [in] areas where surface discharges may have occurred" may be required;	Hercules has addressed the six bullets associated with the referenced comment from NJDEP's 18 November 2010 comments on the Phase I RIR. Specifically, Hercules has: A) designated the AOCs noted in the first two bullets as APRAs (**Table 2-1**) and is conducting pre-remedial design investigations in these areas, B) conducted supplemental surface soil sampling during the Phase II RI in former burning areas referenced in the third and fourth bullets (**Section 7.3**), C) collected nearly 500 additional soil samples in associated with refined delineation in the TNT area to define excavation areas being addressed in the ongoing TNT soil bioremediation remedy (**Appendix B of the TNT RAWP** [Hercules 2020]) as referenced in the fifth and sixth bullets. With the exception of a potential former burning area assessed during the Phase II RI, the areas identified in the referenced comments occur within APRAs excluded from the risk characterization presented in the updated ERA.
14		In addition, it appears that many/most of the Phase II RI soil samples were not collected at the 0-6 inches below ground surface depth interval (for example, see RIR Volume B (Soil Remedial Investigation), Figure B-3, e-page 163).	The surface sample intervals from samples collected during the Phase II RI reflect the surface of soil and 0.5 ft immediately below. When a sample interval is denoted as 0.3 – 0.8 ft bgs, that is an indication that 0.3 ft of leaf litter, organic debris, gravel, asphalt, or other non-soil material was cleared from the ground surface prior to collecting the sample. The associated analytical data is representative of the first 0.5 ft of soil that an ecological receptor would encounter. Soil boring logs for Phase II RI borings were included as **Appendix B of the Phase II Soil RIR – Volume B** (Hercules 2016).

	Section 3.3.1.1 (page 26 – Footnote 3) of RIR Volume F (EE/ERA)	states that the soil samples used in the EE/ERA were collected "with a starting depth of 0 to 1 foot [bgs] and an end depth of no more than 3 feet bgs … and includes intervals spanning the biologically active zone (BAZ)". However, the EE/ERA (RIR Volume F) soil (and sediment) dataset included samples collected from the 0-12 inch bgs interval, including samples that included any portion of the 0-12 inch bgs interval (Volume F [EE/ERA] Section 4.1.1, page 38). Table 4-1 (e-page 141) of RIR Volume F (EE/ERA) provides a summary of the collected soil (and sediment) data. Of the forty-five (45) depth intervals listed, only four (4) solely encompass the 0-6 inch (0.5 feet) bgs depth interval, with an additional nine (9) depth intervals of 0-12 inches (1.0 foot) bgs and seven (7) depth intervals within the 0-12 inch bgs interval. Thus, twenty-five of the soil sample depth intervals listed extend deeper than the 0-12 inch bgs depth of the BAZ.	As discussed in **Section 4.1.1** of the updated ERA, the sample depths included in the ERA dataset have been revised to be more restrictive and focused on shallow soil/sediment intervals. This approach reduces the number of samples in the dataset in favor of a shallower average depth more reflective of the interval where exposures are expected to occur. Specifically, the dataset has been revised so samples with over 50% of their depth interval within the 0 to 12 inch bss interval were included in the EE/ERA dataset. The dataset was specifically filtered to include samples with a start depth of 0-6 inch bss and an end depth of 0-18 in bss.
15		In order to evaluate the suitability of the soil (and sediment) data used in the EE/ERA, Table 4-1 (e-page 141) of RIR Volume F (EE/ERA) should be revised to indicate (a) the total number of soil (and sediment) samples collected in each of the listed depth intervals, and (b) the total number of samples collected in each of the listed depth intervals within each of the 13 soil AOCs	**Table 4-1** has been revised to show the total number of soil samples collected for each method type in each listed depth interval.
16		In addition, to further evaluate the suitability of the soil (and sediment) data used in the EE/ERA: within each of the 13 soil AOCs, an analysis should be conducted – where the appropriate data are available – comparing COPEC concentrations in samples collected within the 0-12 inch bgs depth interval (i.e., the twenty (20) intervals noted above) with those collected at deeper depths to verify that COPEC concentrations are not elevated in the 0-12 bgs depth interval samples compared to those in the other (i.e., "deeper") depth interval samples. If that were the case, inclusion of these deeper samples in the calculations of the mean, 95UCL, etc. statistics would result in underestimates of the COPEC concentrations in the biologically active zone (0-12 inches bgs).	As discussed in **Section 4.1.1** of the updated ERA, the sample depths included in the ERA dataset have been revised to be more restrictive and focused on shallow soil/sediment intervals. This approach reduces the number of samples in the dataset in favor of a shallower average depth more reflective of the interval where exposures are expected to occur. Specifically, the dataset has been revised so samples with over 50% of their depth interval within the 0 to 12 inch bss interval were included in the EE/ERA dataset. The dataset was specifically filtered to include samples with a start depth of 0-6 inch bss and an end depth of 0-18 in bss.
17		Samples collected outside the 0-12 in bgs depth interval (i.e., three (3) intervals listed in EE/ERA Table 4-1 of 1-1.5 ft bgs, 1-1.6 ft bgs, and 1.08-1.58 ft bgs) are outside what is generally considered to be the biologically active zone and therefore should not be used in the EE/ERA. In addition, some samples (5 depth intervals) were collected to depths extending beyond 3 feet bgs (up to 10 ft bgs) as stated in Section 3.3.1.1 (page 26 – Footnote 3) of RIR Volume F (EE/ERA).	As discussed in **Section 4.1.1** of the updated ERA, the sample depths included in the ERA dataset have been revised to be more restrictive and focused on shallow soil/sediment intervals. This approach reduces the number of samples in the dataset in favor of a shallower average depth more reflective of the interval where exposures are expected to occur. Specifically, the dataset has been revised so samples with over 50% of their depth interval within the 0 to 12 inch bss interval were included in the EE/ERA dataset. The dataset was specifically filtered to include samples with a start depth of 0-6 inch bss and an end depth of 0-18 in bss.
General Comment E:	see General Comment D. RIR Volume F (EE/ERA) Table 4-1 (e-page 141) includes sediment samples collected at a depth interval of 1-1.5 feet bgs; these samples are outside what is generally considered to be the biologically active zone (0-12 inches bgs) and therefore should not be used in the EE/ERA. In addition -		As discussed in **Section 4.1.1** of the updated ERA, the sample depths included in the ERA dataset have been revised to be more restrictive and focused on shallow soil/sediment intervals. This approach reduces the number of samples in the dataset in favor of a shallower average depth more reflective of the interval where exposures are expected to occur. Specifically, the dataset has been revised so samples with over 50% of their depth interval within the 0 to 12 inch bss interval were included in the EE/ERA dataset. The dataset was specifically filtered to include samples with a start depth of 0-6 inch bss and an end depth of 0-18 in bss.

18		A cursory review of the data presented in RIR Volume D (Sediment) Appendix G (e-page 9667) indicates that all of the previous SI and Phase I RI sediment samples were collected at depth intervals of 0.5-1 ft bgs, 1-1.5 ft bgs, and 1.5-2 ft bgs. RIR Volume F (EE/ERA) Table 4-1 (e-page 141) includes sediment samples collected at a depth interval of 0.0-0.5 ft bgs; are these limited to the Phase II RIR sediment samples?	**Appendix E** Fourteen field duplicate sediment samples were collected at the 0.0-0.5 ft bgs depth interval during the SI for VOCs only. All other sediment samples in the 0.0-0.5 ft bgs depth interval were collected in 2013 (Phase II RI) or later. Following submission of the EE/ERA in 2016, Hercules implemented the ERAWP included as an appendix to the EE/ERA. The ERAWP concluded that in aquatic areas, additional evaluation of sediment and surface water and aerial insect tissue sample collection was needed within distinct subareas of aquatic exposure areas to validate and refine modeled dietary exposures. Additional sediment samples were collected from every subdrainage area at the 0-0.5 ft depth interval, to target the biologically active zone. Sample locations are presented in **Figures 4-2** through **4-14**, as well as in **Attachment 10**.
General Comment F:	RIR Volume F (EE/ERA), Section 7, page 66:	for HQ calculation and ecological risk characterization purposes, concludes that the HQ-LOAEL "provides a more representative indicator of potential ecological risk to upper-trophic-level [sic] receptors than the HQ-NOAEL"; also see Section 7.4, page 75. Section 6.1.33 of the NJDEP EETG states that both "NOAEL-based and LOAEL-based HQs should be developed to bound the risk estimates". Tables 7-3 to 7-9 (e-pages 181-186), Tables 7-13 to 7-18 (e-pages 191-196), and Tables 7-22 to 7-28 (e-pages 201-207) include HQs calculated using both NOAELs and LOAELs. Section 7.1.3 (and subsections; pages 68-69) should also present and discuss the NOAEL-based HQs.	**Section 7** of the updated ERA discusses HQ interpretation across the bounded range provided by the NOAEL- and LOAEL-based HQs. Tables continue to provide both NOAEL- and LOAEL-based HQs, consistent with the 2016 EE/ERA.

Appendix B

Areas of Presumed Remedial Action – Area Descriptions

Appendix B: Areas of Presumed Remedial Action

Based on a review of the CSM, historical Facility information, and current analytical data, several process/disposal areas within the Remedial Area were identified as areas where remedial action is warranted, irrespective of the outcome of the EE/ERA. The locations, composition, and/or constituents present in these areas align with historical Facility practices and records from the Facility (e.g., disposal areas, explosions).

In the time elapsed since submission of the Phase II RIR, Hercules has initiated remedial actions in certain Areas of Presumed Remedial Action (APRA), implemented pre-design investigations that have refined the spatial extents of certain Areas of Presumed Remedial Action, and conducted field studies to identify additional APRAs (based in part on the terrestrial risk characterization results of the EE/ERA).

The purpose of this appendix is to summarize each of the APRAs that have been omitted from evaluation since identification in the EE/ERA or identified as new APRAs since submittal of the EE/ERA. The ensuing sections address each of the APRAs and provide a brief status update in the form of:

- Relevant background information.
- Action taken up to the present time that contribute to remedy development.
- An outline of the planned remedial approach and estimated timeframe within which it will occur given the current status of the Facility (i.e., redevelopment timeframe, other ongoing remedial actions that may expedite or impede progress of the remedy).

Similarly, the Remedial Timeframe Notification Form includes information on APRAs and is included in **Attachment 2** of the ERA.

Acknowledging the assumed remedial actions in these APRAs, data from these areas are not included in this EE/ERA. **Table 2-1** provides information regarding the history, constituent fate and transport, and presumptive remedy for each area. **Figure 3-2** notes these areas on a site plan. The following sections provide detail on each APRA.

1.1 TNT Area – TNT Soil Bioremediation Project Area

The TNT Area is the largest independent project area (80 acres) within the Facility (**Figure 3-2**) and presents the greatest source of target constituent[1] mass in soil (approximately 69,000 cubic yards) resulting in ongoing impacts to groundwater.

Historically, the TNT Area produced explosives from 1917 to 1919. Processing and operational activities, movement of materials throughout the Facility, incidental releases (e.g., explosions, spills), and ground surface leveling (i.e., demolition of facility buildings) and reconstruction of new facility buildings contributed to the presence of visible TNT in shallow surface soil.

Since 2014, a series of steps have been taken to develop the remedial strategy for the TNT Area. These steps, presented in more detail in the *TNT Project Area Soil Remedial Action Work Plan* (RAWP) (KJ 2020), include:

[1] Target constituents refers to TNT, 2,4-dinitrotoluene (2,4-DNT), 2,6-DNT, 2-amino-4,6-DNT (2-ADNT), and 4-amino-2,6-DNT (4-ADNT)

- Bench scale treatability study [2014].
- Field scale pilot study [2015].
- Refined delineation soil sampling [2017].

In general, these steps allowed for the evaluation of the feasibility and effectiveness of enhanced ex-situ bioremediation as a remedy for target constituents in TNT Area soil. Study results informed the design of a multi-phase remedy involving three primary processes with the following objectives:

- Soil processing (i.e., excavation, blending, and processing in a soil processing plant) to make target constituent source mass present in crystalline forms accessible and amenable to bioremediation (increased surface area-to-volume ratio).
- Ex-situ enhanced bioremediation in constructed treatment cells (bio cells) to degrade target constituent mass (greater than 95 percent [%] reduction in concentrations) over a short period of time (8 to 12 months) to at or less than their respective NJDEP Non-Residential Direct Contact Soil Remediation Standards (DCSRS) via ex-situ bioremediation.
- In-situ biodegradation addresses residual target constituent mass (over approximately 5 years) to facilitate corresponding target constituent concentration reductions in groundwater supporting a monitored natural attenuation groundwater remedy.

The complete remedy development and design is presented in the *TNT Project Area Soil RAWP* (KJ 2020).

As an APRA, ERA activities were incorporated into the TNT Area remedial design to ensure that the proposed remedy remained protective of ecological receptors. ERA findings associated with the *TNT Project Area Soil RAWP* (KJ 2020) identify that the proposed remedy is protective of ecological receptors currently exposed to target constituents in the TNT Area soil. Appendix A of the *TNT Project Area Soil RAWP* (KJ 2020) presents the complete TNT Project Area ERA and its findings in more detail.

Excavation and treatment of TNT Area soil in accordance with the RAWP began in 2024 and will require 5 years to complete the ex-situ treatment phase. In 2029, following the estimated 5 years of annual treatment cycles and backfilling of excavation areas, long term monitoring will begin to document the continued degradation of residuals in soil under in-situ conditions and the anticipated reduction in constituent concentrations in groundwater over time absent a constituent source in soil. Long term monitoring of soil is expected to occur over 5 years (2029 through 2033), with groundwater monitoring to support a monitored natural attenuation (MNA) remedy occurring concurrent with this phase of soil monitoring. Hercules anticipates submitting a TNT Area RAR, updated CEA, and groundwater RAP application in 2034.

1.2 Ammonium Nitrate Area – Former Burning Ground

Historically, the Ammonium Nitrate Area - Former Burning Ground and intervening AOCs [H12-237, H13-1, H13-7] (referred to herein as Former Burning Ground) supported the incineration of off-specification and residual materials. These activities resulted in residual chemical concentrations and physical debris (e.g., ceramic, metal) in surface soil and the observation of only sparse vegetation present within the Former Burning Ground.

In 2013, Hercules initiated pre-design investigation (PDI) activities for the purpose of refining vertical and horizontal extent of debris materials related to historical incineration activities in the Former Burning Ground. Test pits were excavated at approximately 50-foot intervals along the

perimeter and within the Former Burning Ground vicinity in 1-foot lifts, to allow for adequate inspection, to a maximum depth of 10 feet bgs. Test pit locations were biased toward field observations (i.e., visible surface debris, areas of sparse vegetation). PDI activities concluded that debris and constituent (i.e., metals, PAHs, energetics, and dioxins/furans) impacts are limited to surface soil. Such surface soil impacted by debris and constituent concentrations is estimated to measure approximately 1,600 cubic yards in volume. Soil investigated in the Former Burning Ground was found to be non-hazardous. No influence on groundwater quality was observed..

Additional investigation and delineation of dioxins/furans in the Former Burning Ground was completed in 2024. Remedial approach will be assessed in the context of Facility redevelopment in 2026 and will likely involve capping of impacted soil.

1.3 B-Line Area – WWII Disposal Area (M8-1)

The B-Line Area - World War II (WWII) Disposal Area (referred to herein as the WWII Disposal Area) was used as a historical disposal area for drum carcasses, large concrete debris (e.g., block, slab, footings), and other solid waste materials during the period of increased production surrounding WWII. As a result of these activities, the WWII Disposal Area consists of visible surface debris with only moderate to sparse vegetation present on the ground surface. Historic fill is also present throughout the WWII Disposal Area, used as fill to level the debris surface and facilitate debris placement in wet areas. The WWII Disposal Area occupies approximately 6.5 acres between Duck Pond and an emergent/forested freshwater wetland. Freshwater wetlands and associated transition areas make up the majority of the WWII Disposal Area. This designation makes intrusive investigation and remediation activities complex.

Environmental investigations (SI/RI and PDI activities) focused on identifying the composition of the debris, characterizing related chemicals in soil (e.g., energetics, metals, PAHs, PCBs), and defining horizontal and vertical extent of debris in soil. A geophysical survey and test pitting revealed production-related debris (e.g., drum carcasses and pipes) present from 0.0 to 3.5 feet bgs, generally. The production-related debris material was estimated to occupy an estimated volume of 16,000 cubic yards of debris covered with soil. WWII Disposal area soil was found to be non-hazardous. Debris was emplaced both at and below the groundwater table; however, groundwater monitoring sampling results in proximity to the WWII Disposal Area indicate that these solid materials are not impacting groundwater quality.

The remedial approach for the WWII Disposal Area involves debris removal and/or consolidation in combination with capping. This approach provides the least intrusive remedy to address constituents identified in soil and historic fill material while also enhancing/expanding freshwater wetlands. Additional investigation and remediation of the debris material in this area and adjacent wetland areas is anticipated to occur between 2026 and 2030.

1.4 Development Area – Old Burning Ground (M5-3 and AOCs to the Southwest)

Historically, the Development Area - Old Burning Ground and AOCs to the southwest [M5-3, L5-2313, L5-10, L5-2275, L5-539] (referred to herein as Old Burning Ground) was used to incinerate off-speciation product and residual energetic materials. The Old Burning Ground occupies 5.5 acres in a low-lying area that abuts Duck Pond. Old Burning Ground and an adjacent bulk lead processing

operation both drain directly into Duck Pond, which provided a source of water to control burning activities in Old Burning Ground. Incomplete combustion and comingled non-combustible materials resulted in residual chemical constituents as well as physical debris (e.g., ceramic, metal) in surface and shallow subsurface soil. Currently, there is only sparse vegetation present and non-combustible waste materials visible on the ground surface. The former operation area is an open Resource Conservation and Recovery Act (RCRA) Operable Unit (OU).

Environmental investigations identified debris in soil to a depth of approximately 7 feet bgs and COCs (e.g., lead, DNT, PCBs, etc.) in soil to a depth of approximately 10 feet bgs. While soil conditions in Old Burning Ground do not influence nearby surface-water quality, erosion of surface soil from the unvegetated ground surface in Old Burning Ground into surface water and subsequent deposition influenced adjected Duck Pond sediment. And although historical groundwater sampling identified lead in shallow groundwater at concentrations greater than NJDEP GWQS, more recent sampling results do not indicate an influence on groundwater.

Remediation of Toxic Substances Control Act (TSCA)-regulated polychlorinated biphenyls (PCBs) was completed in 2022 in the Old Burning Ground via excavation as part of a sitewide PCB remediation.

PDI work plan development, implementation and remedial design is projected to occur in 2026 through 2028. Remedy implementation will consider that Old Burning Ground is an open RCRA OU, managing the corrective action and closure of this OU.

1.5 Storage Area – WWI Disposal Area (N6-1)

The Storage Area – Disposal Area (N6-1) (referred to herein as World War I [WWI] Disposal Area) occupies approximately 6.5 acres in the Storage Area and was used for disposal during the period of increased production associated with WWI and subsequent years. This area contained materials and solid debris such as steel process vessels, drum carcasses, and large reinforced concrete block. Removal of large metal debris occurred concurrent with Facility demolition. Although WWI Disposal Area mostly revegetated, some debris remains visible at the ground surface.

Hercules has completed environmental investigations and geophysical surveys to characterize debris and soil conditions. The remedial approach will likely include debris consolidation and capping and begin with further environmental investigation and remedial design occurring in 2027 through 2030.

1.6 B-Line Area – South (conglomerate of AOCs)

Historically, various facility process-related buildings and structures (e.g., basins, sheds) stood at the southern end of the B-Line Area near the terminus of Powder Mill Road (**Figure 3-2**). During decommissioning and demolition activities, residual product (e.g., concrete slab) was observed in surface and shallow subsurface soil at various locations in this area. As such, interim remedial measures (e.g., excavation) were implemented.

Currently, the southern end of the B-Line Area is densely vegetated and likely minimizes localized erosion and transport of surface soil and associated constituents into other abutting areas of the Facility.

Hercules will address the removal and/or containment of these materials during the FS process. Additional evaluation and assessment of this area is required to refine the extent of Facility related influences and select an appropriate remedy (where applicable). FS activities are expected to occur in 2027-2030.

1.7 A-Line Area – Northwest (conglomerate of AOCs)

Initially, the A-Line Area – Northwest (referred to herein as the A-Line Area) was used as a dynamite packaging area but was converted to manufacture nitrocellulose-based smokeless powder during Facility expansion in WWI. The A-Line Area was also the origin of a large explosion in 1940. As such, decommissioning/demolition and SI/RI activities identified physical debris, residual source material and explosives in soil surrounding the former building locations. Further environmental investigations indicated that COCs (E&E compounds, metals, PAHs, and SVOCs) occur primarily in surface soil and do not appear mobile in groundwater.

Remedy development includes ongoing AOC closure assessment activities and a refined delineation work plan to refine the extent of potential E&E compounds in the A-Line Area. These activities have been in progress since 2019. Delineation and removal of residual source material is the next step in the remedial approach with final action (i.e., capping) to be assessed and completed in the context of Facility redevelopment in 2026.

1.8 Development Area – Ballistics Range

The Development Area - Ballistics Range (referred to herein as Ballistics Range) was composed of structures associated with testing propellant (i.e., smokeless powder) formulations to achieve manufacturer-specified projectile velocities. These activities resulted in the lead enrichment of Ballistics Range soil via the introduction of lead shot and bullets to surface soil in discrete areas.

Environmental investigations identified lead in soil at concentrations requiring active remediation. Lead pieces are present in surface soil as a solid debris (e.g., projectile fragments). The *Ecological Risk Assessment: Terrestrial Lead Work Plan* (KJ 2018) assesses the physical size of lead particles present in surface soil, nature and extent, and mobility and bioavailability to ecological receptors. Results of this investigation show potential excess risk to upper trophic level avian receptors (e.g., American Robin) via ingestion of lead particles in surface soil. These results were presented to NJDEP during a technical consultation in 2019. Groundwater sampling results support the fate and transport model indicating that elemental lead in surface soil is insoluble and not influencing groundwater.

The remedial approach will target source material removal including soil screening to remove large lead particles, followed by the amendment of remaining soil to bind lead and reduce mobility in the soil column. Further remedial action (i.e., capping) will be assessed in the context of Facility redevelopment. Additional investigation and remediation of soil in this area is anticipated between 2027 and 2029.

1.9 Development Area - Experimental Dynamite Production Area

The Experimental Dynamite Production Area (EDPA) produced and tested formulations of dynamite within the Development Area. NG, a component of dynamite, was manufactured in the NG Area and transported in small batches to the EDPA. EDPA structures supporting formulation and mixing of dynamite were known to have lead floors, conveyances and equipment.

Environmental investigations identified lead in soil at concentrations requiring active remediation. Lead pieces are present in surface soil as a solid debris. The *Ecological Risk Assessment: Terrestrial Lead Work Plan* (KJ 2018) assesses the physical size of lead particles present in surface soil, nature and extent, and mobility and bioavailability to ecological receptors. Results of this investigation show potential excess risk to upper trophic level avian receptors (e.g., American Robin) via ingestion of lead particles in surface soil. These results were presented to NJDEP during a technical consultation in 2019.

Environmental investigations also identified similar constituents in the sediment of an isolated pond adjacent to the area. Additional investigation and remediation of soil in this area is anticipated to occur between 2026 and 2029, with components of the work potentially coordinated with the closure of the Old Burning Ground.

1.10 PETN/NG Area – Acid Recovery

The PETN/NG Area - Acid Recovery (referred to herein as Acid Recovery) was composed of structures associated with the production of NG, and later PETN, from site development in 1871 through Facility closure. Both NG and PETN production processes relied heavily on concentrated nitric acid solutions. Given the sensitivity of NG to static electrical charges, building floors, process equipment and conveyances were typically lined with lead.

Previous environmental investigations discovered lead sheeting and lead debris on the ground surface of the Acid Recovery (AOC B11-11) and areas of stressed vegetation (AOCs C11-4, C11-8, D10-1).

Based on field observations and Facility knowledge, lead exists in the Acid Recovery area in both solid and potentially dissolved forms (e.g., mobile lead particulates entrained in spend acid). During a 2006 sampling event, groundwater samples were collected from an adjacent monitoring well (MW-38) and two addition wells in the NG Area (MW-39 and MW-43). Total lead was not detected in these historical samples. During a 2016 sampling event, one groundwater samples was collected from MW-38. Total lead was detected above NJDEP Groundwater Quality Standards (GWQS).

Hercules anticipates focused removal and/or stabilization of lead in soil in the NG Area. Additional investigation and remediation of soil in this area is anticipated between 2026 and 2028

1.11 Maintenance Area – PCBs

The Maintenance Area – PCBs (referred to herein as Maintenance Area), located in an area of relatively flat topography at the geographic center of the Facility, was optimally located to provide operational support (i.e., power generation, maintenance shops) to the entire Facility. Historically, PCB use at the Facility was limited to dielectric fluids contained in electrical transformers and equipment. The majority of PCB detections in soil occur throughout an approximately 13-acre area in the northeastern portion of the Maintenance Area adjacent to the former powerhouse where the majority of electrical transformers were located. Therefore, PCB impacts in the Maintenance Area soil are thought to be associated with historical maintenance, power generation, and power transmission activities, and regrading/distribution of soil following plant explosions and/or production line retrofits.

Environmental investigations identified total PCB concentrations in soil to generally range between 0.2 and 10 milligrams per kilogram [mg/kg], with three detections in close proximity to each other exceeding TSCA's high-occupancy use threshold concentration (10 mg/kg). Refined delineation

activities occurred between 2018 and 2020 (under a self-implementing plan [SIP] and RAWP) to define those areas where PCBs in soil exceed TSCA's high-occupancy use threshold concentration. Source material (PCB concentrations greater than 10 mg/kg) has been removed, and remaining concentrations do not appear mobile based on recent groundwater quality data. Soil and associated constituents in this area appear stable and generally immobile.

PCB-containing soil (with impacts below TSCA-regulated concentrations) have been delineated and will be capped in the context of future Facility redevelopment.

1.12 Maintenance Area – Acid Production Plant

The Maintenance Area – Acid Production Plant produced sulfuric and nitric acids used to support various manufacturing processes onsite, as well as supply other nearby manufacturing installations.

Environmental investigations identified lead in soil at concentrations requiring active remediation, however lead debris has not been observed on the ground surface. The *Ecological Risk Assessment: Terrestrial Lead Work Plan* (KJ 2018) assesses the physical size of lead particles present in surface soil, nature and extent, and mobility and bioavailability to ecological receptors. Results of this investigation show potential excess risk to upper trophic level avian receptors (e.g., American Robin) via ingestion of lead particles in surface soil. These results were presented to NJDEP during a technical consultation in 2019. Despite this, dissolved lead has been detected at concentrations less than the NJDEP groundwater quality standards in downgradient groundwater monitoring wells.

The remedial approach for this area will include confirmation and delineation sampling to refine the nature and extent of lead in soil. Further remedial action (i.e., capping) will be assessed in the context of Facility redevelopment. Additional investigation and remediation of soil in this area is anticipated between 2027 and 2029.

1.13 NG Area – Former Ponds

The remnant stormwater management features that occupy an area at the base of the hillside on which the NG and PETN production lines sat. Particulates present in stormwater runoff from these manufacturing areas accumulated and settled in the Stormwater Catchment Area. Site demolition altered the drainage and conveyances, and this feature no longer functions as a stormwater catchment.

The *Ecological Risk Assessment: Terrestrial Lead Work Plan* (KJ 2018) assessed the physical size of lead particles present in surface soil, nature and extent, and mobility and bioavailability to ecological receptors. Results of this investigation show potential excess risk to upper trophic level avian receptors (e.g., American Robin) via ingestion of lead particles in surface soil. These results were presented to NJDEP during a technical consultation in 2019.

Environmental investigations identified lead in soil at concentrations requiring active remediation in this feature. Additional investigation and remediation of this feature is anticipated between 2027 and 2029 and will potentially be coordinated with Former Acid Recovery remediation.

Appendix C

Aquatic Ecological Risk Assessment Supplemental Sampling
Memo Implementation

Appendix C: Aquatic ERASSM Implementation

This document, included as an appendix to the Ecological Risk Assessment (ERA), presents and evaluates environmental data collected during implementation of the *Aquatic ERA Supplemental Sampling Memo (ERASSM)* (**Attachment 10** to the ERA) at the Hercules Kenvil Works Facility, located in Kenvil, Morris County, New Jersey (the Facility; **Figure 1-1**). Aquatic ERASSM implementation occurred in July and August 2019 following initial ERAWP implementation and characterization activities in 2016 and 2018.

1.1 Sampling Plan Objectives

The objective of the Aquatic ERASSM field sampling plan was to provide additional lines of evidence (LOEs) in the evaluation of potential risks to benthic invertebrate communities in the seven subdrainage areas where risk remained uncertain following ERAWP implementation. The Aquatic ERASSM (**Attachment 10** to the ERA) targeted seven subdrainage areas of the Facility for supplemental sampling, including additional collection and analyses of sediment, surface water, and/or benthic invertebrate community composition to support refined risk characterization.

Sediment sampling provided:

- Polycyclic aromatic hydrocarbon (PAH) data (list of 34 parent PAHs and alkylated families) for the calculation of equilibrium partitioning sediment benchmark toxicity units (ESBTUs) to evaluate the bioavailability and potential toxicity of PAHs in subdrainage area sediment

- Chromium speciation data to evaluate the mobility and toxicity of chromium in subdrainage area sediment

Surface water sampling provided an additional LOE regarding the form and bioavailability of mercury (Hg) in two subdrainage areas.

Benthic community surveys were conducted in five subdrainage areas. Sample locations were compared to applicable reference locations to help refine understanding of potential risks to benthic invertebrate communities.

The following table outlines sample locations proposed in the ERASSM (**Attachment 10** to the ERA) and constituents of potential ecological concern (COPECs) within each targeted subdrainage area.

Drainage Area	Subdrainage Area	COPEC	Sample Type	No. of Locations	Appendix Figure
NDA	Unnamed Ponds	Hg	• Benthic community survey • Surface water	3	Fig C.1
	Maintenance – Dynamite Area - West	PAHs, Hg	• Benthic community survey • Sediment • Surface water	2	Fig C.2
	Maintenance – Dynamite Area - East	Metals, PAHs	• Sediment	3	Fig C.3
	Maintenance - NG Area	Hg, Ag	• Benthic community survey	2	Fig C.4
	TNT-PETN-NG Ditches	Hg, DNT	• Benthic community survey	3	Fig C.5
	Misc. Offsite Steams - Lower	PAHs	• Sediment	2	Fig C.6
	Central Drainage Basin	Hg	• Benthic community survey	2	Fig C.7
	Development Area Stream	--	• Benthic community survey (reference location)	2	Fig C.9
SDA	Northeast Ponds	--	• Benthic community survey (reference location)	2	Fig C.8

1.2 Sampling Plan Implementation

KJ implemented Aquatic ERASSM field sampling activities from 30 July to 1 August 2019. The following sections detail implementation of and deviations from the Aquatic ERASSM field sampling plan (**Attachment 10** to the ERA).

1.2.1 Sampling Plan Deviations

During Aquatic ERASSM implementation, samples were collected from the most downstream sampling locations to upstream. Locations were geolocated by the field team using a handheld GPS unit.

Sample collection, processing, and analysis followed the procedures outlined in the Aquatic ERASSM (**Attachment 10** to the ERA) with the following noted exceptions:

1. One sediment sample in the Miscellaneous Offsite Streams – Lower (i.e., SD-ERA-C15-MOSL-01[0.0-0.5]) could not be collected at the proposed location due to deep sediment/surface water up to the sampler's waist. This sample was re-located near the proposed location and is identified in **Figure C.6**.

2. One benthic invertebrate community sample in the Central Drainage Basin (i.e., BC-ERA-D14-CDB-01) could not be collected at the proposed location due to deep open water. This sample was re-located and is identified as BC-ERA-D14-CDB-01A in **Figure C.7**.

3. One proposed benthic invertebrate community sample in the TNT-PETN-NG Ditches (i.e., BC-ERA-C12-TPND-01) could not be collected at the proposed location due to a lack of water/habitat. A second attempt was made at sediment sampling location SD-R-C11-04, but the sample could not be collected again due to a lack of water/habitat. A third attempt was made at sampling location SD-R-D13-11, but this location could not be accessed to dense vegetation and poison ivy.

1.2.2 Surface Water Sampling

Five surface water samples, one field blank, and one field duplicate were collected from two subdrainage areas in accordance with NJDEP Field Sampling Procedures Manual (FSPM) (NJDEP 2005) and including:

- Unnamed Ponds (**Figure C.1**)
- Maintenance Dynamite Area – West (**Figure C.2**)

Surface water samples were collected via bottle transfer. Surface water sample locations were collocated with proposed sediment and/or benthic community samples in each area and represented locations where methylmercury (MeHg) analysis was proposed in 2017 but not conducted due to an analytical laboratory error.

Prior to sample collection, in-situ water quality parameters were recorded from six inches above the sediment surface at each sample location. In-situ parameters included temperature, pH, dissolved oxygen, oxidation-reduction potential, turbidity, conductivity, and salinity and results were documented in the field book.

Surface water samples were collected and submitted to Eurofins Lancaster Laboratories Environmental (Eurofins) in Lancaster, PA, a New Jersey Environmental Laboratory Accreditation Program (NJELAP)-accredited laboratory.

1.2.3 Sediment Sampling

Seven sediment samples, two field blanks, and one field duplicate were collected from three subdrainage areas in accordance with the NJDEP FSPM (NJDEP 2005) and including:

- Maintenance Dynamite Area – West (**Figure C.2**)
- Maintenance Dynamite Area – East (**Figure C.3**)
- Miscellaneous Offsite Streams – Lower (**Figure C.6**)

Samples were collected from 0-0.5 ft below ground surface [bgs] after recording in-situ water quality parameters from six inches above the sediment surface. In-situ parameters included temperature, pH, dissolved oxygen, oxidation-reduction potential, turbidity, conductivity, and salinity, and results were documented in the field book.

Sediment samples were collected by driving polycarbonate tubing to desired collection depth using manual techniques (i.e., rubber mallet). At each sediment sampling location, water depth, sediment core recovery and description were measured and recorded in the field book.

Sediment samples were submitted to Eurofins in Lancaster, PA, a NJELAP-accredited laboratory and analyzed for pH, grain size, TOC, and PAHs using USEPA Methods 9040C, D422 ASTM, Lloyd Kahn, and 8270SIM, respectively. AVS/SEM and chromium speciation analyses were conducted in accordance with EPA-821-R-100 and USEPA Methods 6010D and 7196A, respectively.

1.2.4 Benthic Community Sampling

Flowing and/or non-flowing aquatic habitat in five Southern subdrainage areas were targeted for benthic invertebrate community sampling. Target subdrainage areas are as follows:

- Unnamed Ponds (**Fig C.1**)
- Maintenance – Dynamite Area – West (**Fig C.2**)
- Maintenance - NG Area (**Fig C.4**)
- TNT-PETN-NG Ditches (**Fig C.5**)
- Central Drainage Basin (**Fig C.7**)

In addition, two samples were collected from each of two on-site reference locations in the Development Area and Northeast Ponds (**Figures C.8 and C.9**, respectively). These locations occur near the perimeter of the Facility and represent local, ambient conditions beyond the influence of former Facility operations. Reference sample locations targeted similar substrate types and hydrological conditions as the sample locations in the five subdrainage areas.

A Petite Ponar dredge was used due to slow moving and/or standing water habitat with soft sediment or hard bottom (i.e. sand, clay) substrates.

Three replicates per sample were collected at each sampling location from the biologically active zone (BAZ) and composited to create a single sample to reduce biases attributable to spatial variability within the sampling area. The area and volume of each sampler was recorded such that community metrics could be calculated on a per square meter basis to facilitate comparison.

Samples were preserved using isopropyl alcohol and transferred under chain-of-custody procedures to Normandeau Associates in Stowe, Pennsylvania for identification to the lowest practicable taxon and enumeration.

1.3 Data Summary and Results

The following sections present a summary of ERASSM implementation results. Analytical results of sediment and surface water analyses are provided in **Tables C.1 and C.2**, respectively. **Attachment C.1** presents the case narrative and benthic invertebrate identification and enumeration results as prepared by Normandeau. Analytical laboratory reports are provided in **Attachment C.2**.

1.3.1 Methylmercury

In subdrainage areas where potential risk from mercury remained uncertain following ERAWP implementation, supplemental surface water samples were collected and analyzed for total and dissolved MeHg. These subdrainage areas include:

- Unnamed Ponds (**Figure C.1**)
- Maintenance Dynamite Area – West (**Figure C.2**)
- Maintenance Dynamite Area – East (**Figure C.3**)

Results of total and dissolved MeHg analyses in surface water are provided in **Table C.2** and summarized in the table below.

Drainage Area	Subdrainage Area	Methylmercury (ng/L)			
		Total		Dissolved	
		Min.	Max.	Min.	Max.
NDA	Unnamed Ponds	0.49	3.1	ND	0.24
SDA	Maintenance – Dynamite Area – West	0.17	0.38	ND	
	Maintenance – Dynamite Area - East	0.05		ND	

As shown above, total MeHg across subdrainage areas ranged from 0.05 to 3.1 ng/L. Dissolved MeHg was not detected above reporting limits apart from one sample (0.24 ng/L) in Unnamed Ponds, suggesting low potential MeHg mobility and bioavailability to aquatic life in Maintenance – Dynamite Areas – East and West.

While no formal MeHg ESC are available for direct comparison, NJDEP's surface water ESC of 0.77 µg/L for total mercury is greater than three orders of magnitude above the sample result and represents a bioavailable MeHg fraction (dissolved:total MeHg) of approximately half (49.3%), as compared to its paired total MeHg sample. Alternatively, while total and dissolved MeHg in overlying water provides an additional LOE regarding potential risk to aquatic and benthic invertebrates, uncertainty arises when translating potential benthic risk from dissolved concentrations in overlying water to potential risk from direct porewater exposure. Thus, additional investigation of mercury in Unnamed Ponds is recommended despite this LOE.

1.3.2 Chromium Speciation

Potential risk to benthic invertebrates from sediment chromium remained uncertain (i.e., HQ_{LEL} greater than 1) in Maintenance - Dynamite Area - East following ERAWP implementation. Three sediment samples were collected and analyzed in July 2019 for total, trivalent [Cr(III)], and hexavalent chromium [Cr(VI)] in this subdrainage area (**Fig C.3**). Chromium toxicity to aquatic life is dependent on valence state, with Cr(VI) being considerably more toxic and bioavailable.

As shown in **Table C.1**, Sediment Cr(III) concentrations (range: 6.42 – 31.6 mg/kg) were equivalent to total chromium and Cr(VI) was not detected. Results of chromium speciation analysis indicated that sediment conditions in Maintenance - Dynamite Area – East favor the less toxic and less mobile Cr(III). As such, no further investigation of chromium is warranted in this subdrainage area.

1.3.3 Polycyclic Aromatic Hydrocarbons

Consistent with *Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: PAH Mixtures* (USEPA 2003), equilibrium partitioning (EQP) analysis was used to evaluate the bioavailability of PAHs in sediment under given sediment conditions. EQP analysis requires analysis of 17 parent and 17 alkylated family

PAHs (34 total constituents) to develop ESB toxic units (ESBTUs) to predict constituent concentrations in sediment interstitial (pore) water based on equilibrium partitioning between sediment organic carbon and water (USEPA 2003).

The 34-PAH ESBTU is calculated as follows:

$$\sum ESBTU_{FCV} = \sum_{i} \frac{C_{OC,PAHi}}{C_{OC,PAHi,FCVi}}$$

Where,

FCV = Final Chronic Value

$C_{OC,PAHi}$ = organic carbon-normalized concentration of an individual PAH in sediment

$C_{OC,FCVi}$ = the critical organic carbon-normalized concentration of a PAH in sediment, as determined by the FCV

FCVs presented in USEPA (2003) represent ESB toxicity endpoints for PAHs derived using National Water Quality Criteria Guidelines (Stephan et al. 1985).

The historical SI/RI dataset contained results only for 13 priority pollutant PAHs (parent PAHs) and required the application of a 95% uncertainty factor (95%UF) to calculate ESBTUs in eight subdrainage areas targeted for further evaluation in the ERAWP (KJ 2016a).

The 95%UF of 11.5 (Table 6-1 of USEPA 2003) used in the 13-PAH ESBTUs is calculated as follows:

$$\frac{\Sigma ESBTU_{FCV,TOT}}{\Sigma ESTBTU_{FCV,13}}$$

Where,

$\sum ESBTU_{FCV,TOT}$ = the summation of FCV-based ESBTUs for a 34-PAH (total) mixture

$\sum ESBTU_{FCV,13}$ = the summation of FCV-based ESBTUs for a 13-PAH mixture

ESBTUs calculated using the 95%UF are presented in the Updated SSRP (**Attachment 9**).

Further, the Updated SSRP back-calculated a 13-PAH ESBTU benchmark of 8.83 that equated to a 34-PAH ESBTU of 1. This value was initially calculated through comparison to the Central Drainage Basin 34-PAH dataset. Initial PAH ESBTUs calculated using the SI/RI dataset were compared to ESBTUs calculated for the Central Drainage Basin, where ESBTUs were calculated using both the full 34 PAH dataset and the 13 PAH dataset with 95%UF to provide context and account for the overestimation of the 95%UF.

During ERASSM implementation, sediment samples were collected for analysis of 34 PAHs to refine PAH speciation and exposure estimates within subdrainage areas identified to have uncertain risk in the Updated SSRP. Supplemental sediment sampling for 34-PAH analysis was performed in three Southern subdrainage areas targeted for risk refinement, including:

- Maintenance – Dynamite Area – East (**Fig C.3**)
- Maintenance – Dynamite Area – West (**Fig C.2**)

- Miscellaneous Offsite Streams – Lower (**Fig C.6**)

These samples were used to confirm the benchmark value calculated for the Central Drainage Basin. In subdrainage areas where samples for 34-PAH analysis were not collected, the 13-PAH ESBTU benchmark value is used.

Results of this evaluation are presented in **Tables C.3 through C.5** and summarized in the table below.

Aquatic Exposure Areas Sediment PAHs Equilibrium-Partitioning Ecological Screening Benchmark Toxic Unit (ESBTU)			
Drainage Area	**Subdrainage Area**	**ESBTU Benchmark[a]**	**Maximum ESBTU**
SDA	Central Drainage Basin (ESBTU Benchmark Reference)	8.83 / 1	NA
	Maintenance Dynamite Area - East	1	0.01
	Maintenance Dynamite Area - West	1	0.37
	Miscellaneous Offsite Streams – Lower	1	**1.26**

As shown above, results of EqP PAH mixtures analyses indicate that potential risk to benthic invertebrates is possible (i.e., 34-PAH ESBTU greater than 1) in Miscellaneous Offsite Streams – Lower. A dataset evaluation was completed for Miscellaneous Offsite Streams – Lower to better understand the basis for this ESBTU. Two 34-PAH samples were collected within this subdrainage area – one at SD-ERA-B16-MOSL-01 with an ESBTU of 1.26, and one at SD-ERA-C15-MOSL-01 with an ESBTU of 0.01. SD-ERA-B16-MOSL-01 is located adjacent to Rt 46, and the elevated ESBTU appears attributable to run-on from offsite sources. Therefore, this localized elevated ESBTU is attributable to offsite sources and PAHs in sediment throughout the Miscellaneous Offsite Streams – Lower subdrainage area do not warrant further evaluation.

1.3.4 AVS/SEM

In the presence of adequate quantities of sulfide, divalent metals (i.e., Cd, Cu, Pb, Ni, Zn) bind in sulfide complexes and are not bioavailable. In the absence of sufficient sulfide (or excess metals), metals will bind to organic carbon as well. A comparison of sulfide and organic carbon content relative to divalent metals concentrations can be used as an indicator of potential bioavailability, and toxicity, to benthic communities (ITRC 2011). This method gives a better indication of sediment toxicity to benthic organisms than total metals sampling by measuring the bioavailable fraction of metals present. Ratios less than 130 micromoles per gram organic carbon (µmoles/gOC) indicate that toxicity to the benthic community is unlikely; between 130 and 3,000 µmoles/gOC indicate that toxicity is possible, and over 3,000 µmoles/g indicate that toxicity is likely (USEPA 2005).

During the July 2019 sampling event, three sediment samples and one duplicate sample in the Maintenance Dynamite Area – East were analyzed for AVS/SEM. Results of AVS/SEM analysis are provided in **Tables C.1 and C.6** and summarized in the table below.

Sediment Acid-Volatile Sulfide/Simultaneously Extracted Metals Summary		
Drainage Area	Subdrainage Area	Maximum (∑SEM-AVS)/fOC
		µM/gOC
Southern	Maintenance Dynamite Area - East	43.5

Notes: µM/gOC - micromoles per gram organic carbon, fOC – fraction organic carbon

Results of AVS/SEM analysis provide an additional LOE regarding potential risk to benthic invertebrate communities in Maintenance Dynamite Area – East, indicating that potential toxicity to benthic communities is unlikely in this subdrainage area. Thus, no further evaluation is warranted.

1.3.5 Benthic Invertebrate Community Diversity Indices

Benthic community analysis of flowing and non-flowing aquatic habitat relied on common statistical metrics and the NJDEP's high gradient macroinvertebrate index (HGMI). Specific information regarding each analysis follows:

- Shannon-Weiner Diversity Index (H') – measures diversity within the benthic invertebrate community. Typical H' values fall between 1.5 and 3.5 and increase as both the richness and the evenness of the community increases. A lower (closer to 0) H' value indicates a lower level of diversity. Inversely, a higher H' value indicates a greater number of species within the community and a more even distribution of the number of individuals across species.

- Pielou's Species Evenness Index (J') – measures evenness within the benthic invertebrate community. The J' value is constrained between 0 and 1. A lower J' value (closer to 0) indicates less evenness between species in communities and the likely presence of a dominant species. A higher J' (closer to 1) value indicates less variation, and thus greater continuity or evenness, in communities between the species.

- Abundance – measures the number of individuals in each benthic invertebrate community sample. In this case, abundance is calculated by averaging the number of individuals in the replicates across each individual sample location.

- Effective Number of Species (ENS) – measures the number of equally-common species within a community. The ENS represents the real biodiversity and allows for comparison of biodiversity with other communities

The following metrics (Ludwig & Reynolds 1988) were calculated for each benthic invertebrate community sample location as follows:

$$H' = -\sum_{i=1}^{m} (n/N) * \ln(n/N)$$

Where,

n = number of individuals per taxon
N = total number of individuals
m = number of taxa

$$J' = H'/\ln(S)$$

Where,

S = number of species in the benthic invertebrate community sample

And,

$$ENS = e^{H'}$$

The HGMI was calculated at each sample location according to NJDEP's *Standard Operating Procedures Ambient Biological Monitoring Using Benthic Macroinvertebrates* (2007). The HGMI is an indication of water quality that is based on richness and abundance of pollution intolerant and tolerant species. As such, the greater the HGMI score, the higher the quality of the waterbody is expected to be. The assessment rating system is as follows:

HGMI Assessment Rating	Score
Excellent	≥63
Good	<63 - 42
Fair	<42 - 21
Poor	<21

Calculated benthic invertebrate biodiversity indices for flowing and non-flowing aquatic habitat are provided in **Tables C.7 and C.8**, respectively. The table below presents benthic invertebrate community metrics and HGMI scores for flowing and non-flowing aquatic habitat, as applicable**.**

Benthic Invertebrate Biodiversity Indices						
Drainage Area	Subdrainage Area	HGBI	H'	J'	ENS	Abundance
		Lower Bound				
Flowing Aquatic Habitat						
SDA	Development Area Stream (Reference)	20.1	3.52	0.68	34.0	32.0
	Central Drainage Basin	25.2	**1.45**	**0.35**	**4.26**	65.0
	Maintenance Dynamite Area - West	22.0	**2.46**	**0.57**	**11.6**	178.3
	Maintenance NG Area	**14.1**	**1.64**	**0.39**	**5.22**	74.0
	TNT-PETN-NG Ditches	26.4	3.60	0.77	36.4	54.0
Non-flowing Aquatic Habitat						
NDA	Northeast Ponds (Reference)	19.5	1.93	0.48	6.86	181.7
SDA	**Unnamed Ponds**	**7.65**	**1.72**	**0.37**	**5.59**	**37**
	Central Drainage Basin	25.2	**1.45**	**0.35**	**4.26**	**65**

Notes: Bolded values indicate biodiversity indices below Facility-specific flowing or non-flowing habitat reference lower bound.

Comparison of benthic invertebrate samples identified benthic invertebrate communities with Shannon-Weiner Diversity Index scores lower than those represented by reference locations, including flowing aquatic habitat samples in the Maintenance NG Area, Maintenance Dynamite Area – West, and Central Drainage Basin) and non-flowing aquatic habitat samples in the Central

Drainage Basin and Unnamed Ponds, though HGBI scores were lower than reference locations only at Maintenance NG Area within the flowing aquatic habitat. These results provide an additional LOE regarding potential risk to benthic invertebrates.

1.4 Conclusions

Results of the 2016 EE/ERA (Hercules 2016a), ERAWP desktop evaluation (Hercules 2016b), and Updated SSRP (**Attachment 9** to the ERA) guided development of the Aquatic ERASSM (**Attachment 10** to the ERA) and subsequent implementation. As such, results of Aquatic ERASSM implementation supplemented multiple LOEs regarding potential risk to benthic invertebrates. Lines of evidence evaluated from 2016 to 2025 are incorporated in EE/ERA exposure assumptions, where applicable (see Section 5 of the EE/ERA), and risk characterization of benthic invertebrate communities (see Section 7 of the EE/ERA).

Tables 4-10 and 4-11 of the EE/ERA track COPEC progression through the various evaluation methods and the weight-of-evidence (WOE) for risk to benthic invertebrate communities in each subdrainage area are summarized in the following sections.

1.4.1 Northern Subdrainage Area Results Summary

The table below summarizes the results of multiple LOEs for each NDA subdrainage area.

NDA Subdrainage Areas - Benthic Invertebrate Risk Evaluation						
Risk Evaluation Method	**Notes**	**Unnamed Ponds**	**Duck Pond**	**Eastern Tributary**	**Western Tributary**	**Northeast Ponds**
ESC Screen	a	+	+	+	+	+
Background Arsenic Threshold	c	+	-	NA	NA	NA
Mercury Study Comparison	c	+	-	NA	-	NA
Total and Dissolved MeHg	b	+	NA	NA	NA	NA
EqP PAH Analysis	b,c	-	-	NA	NA	-
AVS/SEM and Surrogate TOC%	b,c	-	-	-	-	-
Biological Community Indices	b	+	NA	NA	NA	R
Risk Drivers	-	As, Hg	None	None	None	None
Additional Investigation? (Y/N)	**-**	**Y**	**N**	**N**	**N**	**N**

+ = potential unacceptable risk, retained as a COPEC; - = acceptable risk, not retained as a COPEC; NA = not analyzed; R = reference location; As = arsenic; Hg = mercury; MeHg = methylmercury
[a]Evaluated in Appendix F of KJ (2016) (**Attachment 1**)
[b]Evaluated during ERASSM implementation
[c]Evaluated in Updated SSRP (**Attachment 9**)

As shown above, the WOE in the NDA subdrainage areas indicates acceptable risk within four subdrainage areas. Alternatively, the WOE for the Unnamed Ponds indicates potential unacceptable risk for arsenic and mercury in sediment. Additional investigation into Unnamed Ponds for these COPECs is recommended.

1.4.2 Southern Subdrainage Area Results Summary

The table below summarizes the results of supplemental LOEs for each SDA subdrainage area.

SDA Subdrainage Areas - Benthic Invertebrate Risk Evaluation					
Risk Evaluation Method	**Notes**	**Central Drainage Basin**	**Development Area Stream**	**Maintenance Dynamite Area - East**	**Maintenance Dynamite Area - West**
ESC Screen	a	+	+	+	+

AVS/SEM and Surrogate TOC%	b,c	-	-	-	-
Biological Community Indices	b	+	R	NA	+
Risk Drivers	-	As, Pb, Hg	None	None	As, Pb, Hg
Additional Investigation? (Y/N)	**-**	**Y**	**N**	**N**	**Y**

+ = potential unacceptable risk, retained as a COPEC; - = acceptable risk, not retained as a COPEC; NA = not analyzed; R = reference location; As = arsenic; Pb = lead; Hg = mercury; MeHg = methylmercury
[a]Evaluated in Appendix F of KJ (2016) (**Attachment 1** to the ERA)
[b]Evaluated during ERASSM implementation
[c]Evaluated in Updated SSRP (**Attachment 9** to the ERA)

SDA Subdrainage Areas - Benthic Invertebrate Risk Evaluation Cont.					
Risk Evaluation Method	**Notes**	**Maintenance NG Area**	**Misc. Offsite Streams - Lower**	**Misc. Offsite Streams - Upper**	**TNT-PETN-NG Ditches**
ESC Screen	a	+	+	+	+
Background Arsenic Threshold	c	+	NA	-	+
Mercury Study Comparison	c	+	NA	-	-
EqP PAH Analysis	b,c	-	-	NA	-
AVS/SEM and Surrogate TOC%	b,c	-	-	-	-
Biological Community Indices	b	+	NA	NA	-
Risk Drivers	-	As, Ag, Hg	None	None	None
Additional Investigation? (Y/N)	**-**	**Y**	**N**	**N**	**N**

+ = potential unacceptable risk, retained as a COPEC; - = acceptable risk, not retained as a COPEC; NA = not analyzed; As = arsenic; Ag = silver; Pb = lead; Hg = mercury; MeHg = methylmercury
[a]Evaluated in Appendix F of KJ (2016) (**Attachment 1** to the ERA)
[b]Evaluated during ERASSM implementation
[c]Evaluated in Updated SSRP (**Attachment 9** to the ERA)

The WOE in SDA subdrainage areas indicates acceptable risk within five subdrainage areas. Alternatively, the WOE for the Central Drainage Basin, Maintenance NG Area, and Maintenance – Dynamite Area - West indicates potential unacceptable risk for arsenic, lead, mercury, and/or silver

in sediment. Additional investigation into these SDA subdrainage areas for these COPECs is recommended.

CASE NARRATIVE

SUBJECT: Benthic Macroinvertebrate Sample Analysis: Hercules LLC-Kenvil Works Facility Project
(Normandeau Associates, Inc. Project Number 24368.000)

Dear Ms. Sterner:

On 5 August 2019 Normandeau Associate's Stowe, Pennsylvania Laboratory received a set of 42 sediment samples collected by Kennedy/Jenks for a benthic macroinvertebrate taxonomic analysis. Quantitative samples were collected with a Petite Ponar Grab, from a series of ponds and streams near the Kenvil Works Site in New Jersey. Fourteen sample locations were visited and three replicate grabs were taken from each location. These were analyzed under an Analytical Subcontractor Agreement dated: July 15,2019 (K/J Project No.: 1540001*64).

Methodology

The samples were analyzed according to Normandeau procedures:

- EA 5 – *Sorting of Macroinvertebrates from Sample Residue.*
- EA 6 – *Identification and Enumeration of Macroinvertebrates.*
- EA 9 – *Macroinvertebrate Subsampling.*

In the lab the sample matrices were rinsed through a 500-micron sieve and distributed into a gridded pan partially filled with water. Invertebrate specimens were then removed from the matrices under magnification and sorted by type into glass vials.

The sample matrices was processed in entirety and any sub-sampling required limited to abundant (i.e., > 100 individuals) taxonomic groups. To accomplish this, the matrices were first processed in entirety to remove specimens from all non-abundant taxa. Following this, the matrices were placed into a Folsom Splitter and divided into quarter fractions. A fraction was selected at random and specimens from abundant taxa also removed. The counts for abundant taxa were then estimated according to the amount of matrix re-processed.

The invertebrates were identified to the genus/species taxonomic end point, as their age and condition allowed using dissecting and compound microscopes. Results were entered into report-ready data tables in Excel and submitted to Kennedy/Jenks for review.

Quality Assurance/Quality Control

According to protocol, Quality Assurance/Quality Control was applied to selected samples for both the processing and taxonomic identification phases of the analysis.

For processing, randomly selected samples were independently re-sorted to determine the efficiency of both taxa and specimen removal. The results were considered acceptable if a standard of 90 percent was attained. Quality Control results are shown below:

Sample Processing (sorting):

Sample	Sample Date	Taxa	Specimens
BC-ERA-I5-REF-02-02	29 July 2019	100.0%	100.2%
BC-ERA-Q4-REF-01-01	29 July 2019	100.0%	93.8%

In addition, a Quality Assurance check was applied to nine samples where sub-sampling was conducted. This was accomplished by tallying any specimens found within non-abundant groups, from the re-sorted fraction, and then estimating the number of taxa and specimens missed according to the amount of matrix re-processed. Quality Assurance results are shown here:

Sample Processing:

Sample	Sample Date	Taxa	Specimens
BC-ERA-D13-MDW-01-01	30 July 2019	100.0%	98.3%
BC-ERA-D13-MDW-02-01	30 July 2019	100.0%	96.4%
BC-ERA-N7-UP-02-01	30 July 2019	100.0%	100.0%
BC-ERA-N7-UP-02-03	30 July 2019	100.0%	95.9%
BC-ERA-N7-UP-05-01	30 July 2019	90.9%	96.1%
BC-ERA-N7-UP-05-02	30 July 2019	100.0%	94.1%
BC-ERA-N7-UP-05-02	30 July 2019	100,0%	97.5%
BC-ERA-Q4-REF-01-02	29 July 2019	100.0%	98.0%
BC-ERA-R4-REF-01-03	29 July 2019	100.0%	100.0%

For taxonomy, selected samples were re-analyzed by a second Biologist to determine the accuracy of the identifications. The results were considered acceptable if 90 percent or more of the identifications were confirmed. Quality Control results are given here:

Sample Analysis (taxonomy):

Sample	Sample Date	Taxa	Gross Count
BC-ERA-D13-MDW-01-01	30 July 2019	100.0%	98.3%
BC-ERA-E13-CDB-01-02	1 Aug. 2019	94.7%	97.4%
BC-ERA-I5-REF-01-02	29 July 2019	100.0%	96.3%

Normandeau taxonomists are certified by the Society for Freshwater Science.

Results

A cumulative total of 120 discrete taxa was identified from the sample set (all stations/reps. combined). The data from individual stations were condensed to three metrics: 1) Richness; 2) Density; and 3) Shannon Diversity (base e).

The metric calculations produced the following ranges at individual stations (three reps. combined):

- Richness: 12 taxa at Station BC-ERA-M7-UP-01 to 37 taxa at Station BC-ERA-I5-REF-01.
- Density: 1,391/m^2 at Sta. BC-ERA-I5-REF-02 to 16,841/m^2 at Sta.BC-ERA-D13-MDW-02.
- Diversity: 0.93 at Sta. BC-ERA-D14-CDB-01A to 2.49 at Sta. BC-ERA-C13-TPND-01.

Respectively Submitted,

George M. Christian
(Senior Scientist/Laboratory Manager)

RE: Low Level Mercury

Enclosed are the analytical results for samples received by Eurofins Frontier Global Sciences. All quality control measurements are within established control limits and there were no analytical difficulties encountered with the exception of those listed in the case narrative section of this report.

If you have any questions concerning this report, please feel free to contact me.

Sincerely,

Amy Goodall
Project Manager

Eurofins Lancaster Environmental, LLC	Project: Low Level Mercury	
2425 New Holland Pike	Project Number: 2056384	**Reported:**
Lancaster PA, 17601	Project Manager: Hannah Cottman	21-Aug-19 10:10

SAMPLE RECEIPT

Samples were received at Eurofins Frontier Global Sciences (EFGS) on 02-Aug-19 11:25. The samples were received intact, on-ice within a sealed cooler at

Cooler	Temp C°
Default Cooler	0.4

Sample 9H00033-16, 'BD073019A Dissolved' was received unpreserved. Sample was preserved on the day of receipt, but it was preserved outside the 48 hour holding time. Client was notified via email.

SAMPLE PREPARATION AND ANALYSIS

Samples were prepared and analyzed for methyl mercury by cold vapor gas chromatography atomic fluorescence spectrometry (CV-GC-AFS) in accordance with EPA 1630 (EFGS-070). Samples 9H00033-01 and 9H00033-02 were used as the source QC samples for the Matrix Spike (MS) and the Matrix Spike Duplicate (MSD).

ANALYTICAL AND QUALITY CONTROL ISSUES

Method blanks were prepared for every preparation to assess possible blank contribution from the sample preparation procedure. The method blanks were carried through the entire analytical procedure. All blanks fell within the established acceptance criteria with the exception of any items narrated above or flagged and described in the notes and definitions section of the report.

Liquid spikes, certified reference material (CRM) or a quality control samples (QCS) were prepared for every preparation as a measure of accuracy. All liquid spikes, CRMs and/or QCS samples fell within the established acceptance criteria with the exception of any items narrated above or flagged and described in the notes and definitions section of the report.

As an additional measure of the accuracy of the methods used and to check for matrix interference, matrix spikes (MS) and matrix spike duplicates (MSD) were digested and analyzed. All of the matrix spike recoveries fell within the established acceptance criteria with the exception of any items flagged and described in the notes and definitions section of the report.

A reasonable measure of the precision of the analytical methods is the relative percent difference (RPD) between a matrix spike recovery and a matrix spike duplicate recovery and between laboratory control sample recovery and laboratory control sample duplicate recoveries. All of the relative percent differences fell within established acceptance criteria with the exception of any items flagged and described in the notes and definitions section of the report.

Eurofins Lancaster Environmental, LLC	Project: Low Level Mercury	
2425 New Holland Pike	Project Number: 2056384	**Reported:**
Lancaster PA, 17601	Project Manager: Hannah Cottman	21-Aug-19 10:10

Notes and Definitions

U	Analyte was not detected and is reported as less than the LOD or as defined by the client. The LOD has been adjusted for any dilution or concentration of the sample.
QM-07	The spike recovery was outside control limits for the MS and/or MSD. The batch was accepted based on LCS and LCSD recoveries within control limits and, when analysis permits, acceptable AS/ASD.
DET	Analyte DETECTED
ND	Analyte NOT DETECTED at or above the method detection limit if reported to the MDL or above the reporting limit if reported to the MRL.
NR	Not Reported
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference

Eurofins Frontier Global Sciences, LLC

The results in this report only apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

Amy Goodall, Project Manager

Explanation of Symbols and Abbreviations

The following defines common symbols and abbreviations used in reporting technical data:

BMQL	Below Minimum Quantitation Level	**mL**	milliliter(s)
C	degrees Celsius	**MPN**	Most Probable Number
cfu	colony forming units	**N.D.**	non-detect
CP Units	cobalt-chloroplatinate units	**ng**	nanogram(s)
F	degrees Fahrenheit	**NTU**	nephelometric turbidity units
g	gram(s)	**pg/L**	picogram/liter
IU	International Units	**RL**	Reporting Limit
kg	kilogram(s)	**TNTC**	Too Numerous To Count
L	liter(s)	**µg**	microgram(s)
lb.	pound(s)	**µL**	microliter(s)
m3	cubic meter(s)	**umhos/cm**	micromhos/cm
meq	milliequivalents	**MCL**	Maximum Contamination Limit
mg	milligram(s)		

<	less than
>	greater than
ppm	parts per million - One ppm is equivalent to one milligram per kilogram (mg/kg) or one gram per million grams. For aqueous liquids, ppm is usually taken to be equivalent to milligrams per liter (mg/l), because one liter of water has a weight very close to a kilogram. For gases or vapors, one ppm is equivalent to one microliter per liter of gas.
ppb	parts per billion
Dry weight basis	Results printed under this heading have been adjusted for moisture content. This increases the analyte weight concentration to approximate the value present in a similar sample without moisture. All other results are reported on an as-received basis.

Analytical test results meet all requirements of the associated regulatory program (i.e., NELAC (TNI), DoD, and ISO 17025) unless otherwise noted under the individual analysis.

Measurement uncertainty values, as applicable, are available upon request.

Tests results relate only to the sample tested. Clients should be aware that a critical step in a chemical or microbiological analysis is the collection of the sample. Unless the sample analyzed is truly representative of the bulk of material involved, the test results will be meaningless. If you have questions regarding the proper techniques of collecting samples, please contact us. We cannot be held responsible for sample integrity, however, unless sampling has been performed by a member of our staff.

This report shall not be reproduced except in full, without the written approval of the laboratory.

Times are local to the area of activity. Parameters listed in the 40 CFR Part 136 Table II as “analyze immediately” are not performed within 15 minutes.

WARRANTY AND LIMITS OF LIABILITY - In accepting analytical work, we warrant the accuracy of test results for the sample as submitted. THE FOREGOING EXPRESS WARRANTY IS EXCLUSIVE AND IS GIVEN IN LIEU OF ALL OTHER WARRANTIES, EXPRESSED OR IMPLIED. WE DISCLAIM ANY OTHER WARRANTIES, EXPRESSED OR IMPLIED, INCLUDING A WARRANTY OF FITNESS FOR PARTICULAR PURPOSE AND WARRANTY OF MERCHANTABILITY. IN NO EVENT SHALL EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL, LLC BE LIABLE FOR INDIRECT, SPECIAL, CONSEQUENTIAL, OR INCIDENTAL DAMAGES INCLUDING, BUT NOT LIMITED TO, DAMAGES FOR LOSS OF PROFIT OR GOODWILL REGARDLESS OF (A) THE NEGLIGENCE (EITHER SOLE OR CONCURRENT) OF EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL AND (B) WHETHER EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL HAS BEEN INFORMED OF THE POSSIBILITY OF SUCH DAMAGES. We accept no legal responsibility for the purposes for which the client uses the test results. No purchase order or other order for work shall be accepted by Eurofins Lancaster Laboratories Environmental which includes any conditions that vary from the Standard Terms and Conditions, and Eurofins Lancaster Laboratories Environmental hereby objects to any conflicting terms contained in any acceptance or order submitted by client.

eurofins | Lancaster Laboratories Environmental

Data Qualifiers

Qualifier	Definition
C	Result confirmed by reanalysis
D1	Indicates for dual column analyses that the result is reported from column 1
D2	Indicates for dual column analyses that the result is reported from column 2
E	Concentration exceeds the calibration range
K1	Initial Calibration Blank is above the QC limit and the sample result is ND
K2	Continuing Calibration Blank is above the QC limit and the sample result is ND
K3	Initial Calibration Verification is above the QC limit and the sample result is ND
K4	Continuing Calibration Verification is above the QC limit and the sample result is ND
J (or G, I, X)	Estimated value >= the Method Detection Limit (MDL or DL) and < the Limit of Quantitation (LOQ or RL)
P	Concentration difference between the primary and confirmation column >40%. The lower result is reported.
P^	Concentration difference between the primary and confirmation column > 40%. The higher result is reported.
U	Analyte was not detected at the value indicated
V	Concentration difference between the primary and confirmation column >100%. The reporting limit is raised due to this disparity and evident interference.
W	The dissolved oxygen uptake for the unseeded blank is greater than 0.20 mg/L.
Z	Laboratory Defined - see analysis report

Additional Organic and Inorganic CLP qualifiers may be used with Form 1 reports as defined by the CLP methods.
Qualifiers specific to Dioxin/Furans and PCB Congeners are detailed on the individual Analysis Report.

Quality Control Summary

Client Name: Hercules Incorporated
Group Number: 2056219
Reported: 09/17/2019 16:37

Matrix QC may not be reported if insufficient sample or site-specific QC samples were not submitted. In these situations, to demonstrate precision and accuracy at a batch level, a LCS/LCSD was performed, unless otherwise specified in the method.

All Inorganic Initial Calibration and Continuing Calibration Blanks met acceptable method criteria unless otherwise noted on the Analysis Report.

Explanation of Symbols and Abbreviations

The following defines common symbols and abbreviations used in reporting technical data:

BMQL	Below Minimum Quantitation Level	**mL**	milliliter(s)
C	degrees Celsius	**MPN**	Most Probable Number
cfu	colony forming units	**N.D.**	non-detect
CP Units	cobalt-chloroplatinate units	**ng**	nanogram(s)
F	degrees Fahrenheit	**NTU**	nephelometric turbidity units
g	gram(s)	**pg/L**	picogram/liter
IU	International Units	**RL**	Reporting Limit
kg	kilogram(s)	**TNTC**	Too Numerous To Count
L	liter(s)	**µg**	microgram(s)
lb.	pound(s)	**µL**	microliter(s)
m3	cubic meter(s)	**umhos/cm**	micromhos/cm
meq	milliequivalents	**MCL**	Maximum Contamination Limit
mg	milligram(s)		

<	less than
>	greater than
ppm	parts per million - One ppm is equivalent to one milligram per kilogram (mg/kg) or one gram per million grams. For aqueous liquids, ppm is usually taken to be equivalent to milligrams per liter (mg/l), because one liter of water has a weight very close to a kilogram. For gases or vapors, one ppm is equivalent to one microliter per liter of gas.
ppb	parts per billion
Dry weight basis	Results printed under this heading have been adjusted for moisture content. This increases the analyte weight concentration to approximate the value present in a similar sample without moisture. All other results are reported on an as-received basis.

Analytical test results meet all requirements of the associated regulatory program (i.e., NELAC (TNI), DoD, and ISO 17025) unless otherwise noted under the individual analysis.

Measurement uncertainty values, as applicable, are available upon request.

Tests results relate only to the sample tested. Clients should be aware that a critical step in a chemical or microbiological analysis is the collection of the sample. Unless the sample analyzed is truly representative of the bulk of material involved, the test results will be meaningless. If you have questions regarding the proper techniques of collecting samples, please contact us. We cannot be held responsible for sample integrity, however, unless sampling has been performed by a member of our staff.

This report shall not be reproduced except in full, without the written approval of the laboratory.

Times are local to the area of activity. Parameters listed in the 40 CFR Part 136 Table II as “analyze immediately” are not performed within 15 minutes.

WARRANTY AND LIMITS OF LIABILITY - In accepting analytical work, we warrant the accuracy of test results for the sample as submitted. THE FOREGOING EXPRESS WARRANTY IS EXCLUSIVE AND IS GIVEN IN LIEU OF ALL OTHER WARRANTIES, EXPRESSED OR IMPLIED. WE DISCLAIM ANY OTHER WARRANTIES, EXPRESSED OR IMPLIED, INCLUDING A WARRANTY OF FITNESS FOR PARTICULAR PURPOSE AND WARRANTY OF MERCHANTABILITY. IN NO EVENT SHALL EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL, LLC BE LIABLE FOR INDIRECT, SPECIAL, CONSEQUENTIAL, OR INCIDENTAL DAMAGES INCLUDING, BUT NOT LIMITED TO, DAMAGES FOR LOSS OF PROFIT OR GOODWILL REGARDLESS OF (A) THE NEGLIGENCE (EITHER SOLE OR CONCURRENT) OF EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL AND (B) WHETHER EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL HAS BEEN INFORMED OF THE POSSIBILITY OF SUCH DAMAGES. We accept no legal responsibility for the purposes for which the client uses the test results. No purchase order or other order for work shall be accepted by Eurofins Lancaster Laboratories Environmental which includes any conditions that vary from the Standard Terms and Conditions, and Eurofins Lancaster Laboratories Environmental hereby objects to any conflicting terms contained in any acceptance or order submitted by client.

Data Qualifiers

Qualifier	Definition
C	Result confirmed by reanalysis
D1	Indicates for dual column analyses that the result is reported from column 1
D2	Indicates for dual column analyses that the result is reported from column 2
E	Concentration exceeds the calibration range
K1	Initial Calibration Blank is above the QC limit and the sample result is ND
K2	Continuing Calibration Blank is above the QC limit and the sample result is ND
K3	Initial Calibration Verification is above the QC limit and the sample result is ND
K4	Continuing Calibration Verification is above the QC limit and the sample result is ND
J (or G, I, X)	Estimated value >= the Method Detection Limit (MDL or DL) and < the Limit of Quantitation (LOQ or RL)
P	Concentration difference between the primary and confirmation column >40%. The lower result is reported.
P^	Concentration difference between the primary and confirmation column > 40%. The higher result is reported.
U	Analyte was not detected at the value indicated
V	Concentration difference between the primary and confirmation column >100%. The reporting limit is raised due to this disparity and evident interference.
W	The dissolved oxygen uptake for the unseeded blank is greater than 0.20 mg/L.
Z	Laboratory Defined - see analysis report

Additional Organic and Inorganic CLP qualifiers may be used with Form 1 reports as defined by the CLP methods.
Qualifiers specific to Dioxin/Furans and PCB Congeners are detailed on the individual Analysis Report.

The recovery for the method blank surrogate(s) is outside the QC acceptance limits as noted on the QC Summary. The recovery for a target analyte(s) in the Laboratory Control Spike(s) is outside the QC acceptance limits as noted on the QC Summary. The LCS/LCSD surrogate(s) recovery is outside the QC acceptance limits as noted on the QC Summary. Sufficient sample was not available to repeat the analysis.

*=This limit was used in the evaluation of the final result

The recovery for the sample surrogate(s) is outside the QC acceptance limits as noted on the QC Summary. The following action was taken: The sample was re-extracted outside the method required holding time and the QC is compliant. All results are reported from both trials.

Metals	**SW-846 6010D Rev.4, July 2014**		**mg/kg**	**mg/kg**	**mg/kg**	
06951	Chromium	7440-47-3	6.42	0.180	1.28	1
02829	Trivalent Chromium soils[1]	16065-83-1	6.4	0.18	1.3	1

The Trivalent Chromium result is calculated by subtracting Hexavalent Chromium from Total Chromium.

The recovery for the sample surrogate(s) is outside the QC acceptance limits as noted on the QC Summary. The following action was taken: The sample was re-extracted outside the method required holding time and the QC is compliant. All results are reported from both trials.

Metals	**SW-846 6010D Rev.4, July 2014**		**mg/kg**	**mg/kg**	**mg/kg**	
06951	Chromium	7440-47-3	31.6	0.828	5.91	1
02829	Trivalent Chromium soils[1]	16065-83-1	31.6	0.83	5.9	1

The Trivalent Chromium result is calculated by subtracting Hexavalent Chromium from Total Chromium.

Wet Chemistry	**Lloyd Kahn**		**mg/kg**	**mg/kg**	**mg/kg**

Sample Comments

State of New Jersey Lab Certification No. PA011

[1] = This analyte was not on the laboratory's NJ DEP Scope of Accreditation at the time of analysis.

B (for Inorganic tests) = estimated value: The result is >/= the Method Detection Limit (MDL) and < the Limit of Quantitation (LOQ).
Note: LOQ = PQL

Quality Control Summary

Client Name: Hercules Incorporated Group Number: 2056546
Reported: 09/17/2019 16:36

Matrix QC may not be reported if insufficient sample or site-specific QC samples were not submitted. In these situations, to demonstrate precision and accuracy at a batch level, a LCS/LCSD was performed, unless otherwise specified in the method.

All Inorganic Initial Calibration and Continuing Calibration Blanks met acceptable method criteria unless otherwise noted on the Analysis Report.

Explanation of Symbols and Abbreviations

The following defines common symbols and abbreviations used in reporting technical data:

BMQL	Below Minimum Quantitation Level	**mL**	milliliter(s)
C	degrees Celsius	**MPN**	Most Probable Number
cfu	colony forming units	**N.D.**	non-detect
CP Units	cobalt-chloroplatinate units	**ng**	nanogram(s)
F	degrees Fahrenheit	**NTU**	nephelometric turbidity units
g	gram(s)	**pg/L**	picogram/liter
IU	International Units	**RL**	Reporting Limit
kg	kilogram(s)	**TNTC**	Too Numerous To Count
L	liter(s)	**µg**	microgram(s)
lb.	pound(s)	**µL**	microliter(s)
m3	cubic meter(s)	**umhos/cm**	micromhos/cm
meq	milliequivalents	**MCL**	Maximum Contamination Limit
mg	milligram(s)		

<	less than
>	greater than
ppm	parts per million - One ppm is equivalent to one milligram per kilogram (mg/kg) or one gram per million grams. For aqueous liquids, ppm is usually taken to be equivalent to milligrams per liter (mg/l), because one liter of water has a weight very close to a kilogram. For gases or vapors, one ppm is equivalent to one microliter per liter of gas.
ppb	parts per billion
Dry weight basis	Results printed under this heading have been adjusted for moisture content. This increases the analyte weight concentration to approximate the value present in a similar sample without moisture. All other results are reported on an as-received basis.

Analytical test results meet all requirements of the associated regulatory program (i.e., NELAC (TNI), DoD, and ISO 17025) unless otherwise noted under the individual analysis.

Measurement uncertainty values, as applicable, are available upon request.

Tests results relate only to the sample tested. Clients should be aware that a critical step in a chemical or microbiological analysis is the collection of the sample. Unless the sample analyzed is truly representative of the bulk of material involved, the test results will be meaningless. If you have questions regarding the proper techniques of collecting samples, please contact us. We cannot be held responsible for sample integrity, however, unless sampling has been performed by a member of our staff.

This report shall not be reproduced except in full, without the written approval of the laboratory.

Times are local to the area of activity. Parameters listed in the 40 CFR Part 136 Table II as “analyze immediately” are not performed within 15 minutes.

WARRANTY AND LIMITS OF LIABILITY - In accepting analytical work, we warrant the accuracy of test results for the sample as submitted. THE FOREGOING EXPRESS WARRANTY IS EXCLUSIVE AND IS GIVEN IN LIEU OF ALL OTHER WARRANTIES, EXPRESSED OR IMPLIED. WE DISCLAIM ANY OTHER WARRANTIES, EXPRESSED OR IMPLIED, INCLUDING A WARRANTY OF FITNESS FOR PARTICULAR PURPOSE AND WARRANTY OF MERCHANTABILITY. IN NO EVENT SHALL EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL, LLC BE LIABLE FOR INDIRECT, SPECIAL, CONSEQUENTIAL, OR INCIDENTAL DAMAGES INCLUDING, BUT NOT LIMITED TO, DAMAGES FOR LOSS OF PROFIT OR GOODWILL REGARDLESS OF (A) THE NEGLIGENCE (EITHER SOLE OR CONCURRENT) OF EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL AND (B) WHETHER EUROFINS LANCASTER LABORATORIES ENVIRONMENTAL HAS BEEN INFORMED OF THE POSSIBILITY OF SUCH DAMAGES. We accept no legal responsibility for the purposes for which the client uses the test results. No purchase order or other order for work shall be accepted by Eurofins Lancaster Laboratories Environmental which includes any conditions that vary from the Standard Terms and Conditions, and Eurofins Lancaster Laboratories Environmental hereby objects to any conflicting terms contained in any acceptance or order submitted by client.

eurofins | Lancaster Laboratories Environmental

Data Qualifiers

Qualifier	Definition
C	Result confirmed by reanalysis
D1	Indicates for dual column analyses that the result is reported from column 1
D2	Indicates for dual column analyses that the result is reported from column 2
E	Concentration exceeds the calibration range
K1	Initial Calibration Blank is above the QC limit and the sample result is ND
K2	Continuing Calibration Blank is above the QC limit and the sample result is ND
K3	Initial Calibration Verification is above the QC limit and the sample result is ND
K4	Continuing Calibration Verification is above the QC limit and the sample result is ND
J (or G, I, X)	Estimated value >= the Method Detection Limit (MDL or DL) and < the Limit of Quantitation (LOQ or RL)
P	Concentration difference between the primary and confirmation column >40%. The lower result is reported.
P^	Concentration difference between the primary and confirmation column > 40%. The higher result is reported.
U	Analyte was not detected at the value indicated
V	Concentration difference between the primary and confirmation column >100%. The reporting limit is raised due to this disparity and evident interference.
W	The dissolved oxygen uptake for the unseeded blank is greater than 0.20 mg/L.
Z	Laboratory Defined - see analysis report

Additional Organic and Inorganic CLP qualifiers may be used with Form 1 reports as defined by the CLP methods.
Qualifiers specific to Dioxin/Furans and PCB Congeners are detailed on the individual Analysis Report.

Appendix D

Terrestrial Lead Work Plan Implementation

Appendix D: Terrestrial Lead Work Plan Implementation

This document, included as an appendix of the Ecological Risk Assessment (ERA), presents and evaluates environmental data collected during implementation of the *Terrestrial Lead Work Plan* (TWLP) (**Attachment 8**) at the Hercules Kenvil Works Facility, located in Kenvil, Morris County, New Jersey (the Facility; Figure 1-1). TLWP implementation activities occurred in December 2018.

D.1 Field Sampling Plan Objectives

The TLWP established a field sampling program to refine existing conclusions regarding lead in Facility soil and its potential risk to terrestrial receptors (i.e., American Robin) and provide additional lines of evidence related to terrestrial assessment endpoints.

The objective of the TLWP field sampling plan was to evaluate bioavailability, chemical speciation, and physical form of lead in soil of areas of enrichment (AoEs) and the potential for upper trophic level receptor prey items to bioaccumulate lead.

D.2 Areas of Enrichment

Historical information regarding uses of lead during operations at the Facility indicates that lead was most commonly used in elemental form as an anti-static, non-sparking material in various stages/structures in manufacturing processes. Based on operational layout and specific process-related uses, lead was limited to distinct areas where raw, intermediate, and final products remained sensitive to electrical charges and/or concentrated acids were used in the production processes.

Acknowledging that lead was used in discrete areas, the TLWP identified five AoEs where lead concentrations in surface soil (i.e., samples with all or a portion of the sample interval between 0 and 2 feet below ground surface [ft bgs]) disproportionately influenced potential ecological risk and merit further evaluation.

These targeted AoEs included:

- **AoE-1** - Development Area – Experimental Dynamite Production Area [EDPA]
- **AoE-2** - Development Area – Ballistics Range
- **AoE-3** - PETN/NG Area – Acid Recovery
- **AoE-4** - NG Area – Former Ponds
- **AoE-5** - Maintenance Area – Acid Production Plant

The boundaries of these AoEs are presented in **Figure 3-2** of the ERA.

In the ERAWP (KJ 2016) and TLWP (**Attachment 8**), approximately 210 acres of the Facility were targeted for redevelopment during TLWP development and implementation. During this period, AoE-5 occurred within the redevelopment footprint, and an engineering control (i.e., remedial cap)

was planned that would eliminate potential ecological exposure pathways in this AoE. Thus, AoE-5 was not included in 2018 field sampling plan.

The following sections detail implementation of and deviations from the TLWP field sampling plan (KJ 2018). Results of TLWP implementation relevant to the portions of the Remedial Area where the potential for ecological risk is uncertain are incorporated in the ERA as follows:

Section 5.1.1.1.1.1 - Sequential Extraction Procedure (SEP) Analysis Results.

D.3 Field Sampling Plan Implementation

KJ implemented TLWP field sampling activities in December 2018. Proposed sample locations in each AoE were focused on historical site investigation/remedial investigation [SI/RI] sample locations with elevated lead concentrations. In general, the primary sample location was that of the historical SI/RI sample and step-out locations (eight total) were collected, where possible (see Section D.3), at 15 and 30 feet [ft] from the primary sample location in four cardinal directions. The sample location selection process and rationale are detailed in the TLWP (**Attachment 8**).

Soil samples were collected from the top 6-inch interval (0 to 0.5 ft bgs) via stainless steel hand trowel, dried and sieved in accordance with the TLWP.

Figures D.1 through D.3 illustrate primary and step-out sample locations in each of three AoEs, distinguishing them by color based on status (i.e., sampled/not sampled, analyzed/not analyzed). The following table summarizes the number of samples collected and analyzed within each AoE.

Area of Enrichment	No. of Sample Locations					
	Primary		Step-Out		Total	
	Collected	Analyzed	Collected	Analyzed	Collected	Analyzed
AoE-1	5	2	38	5	43	7
AoE-2	4	2	29	4	33	6
AoE-3	4	2	31	4	35	6

D.4 Field Sampling Plan Deviations

As mentioned above, sample collection, processing, and analysis followed the procedures outlined in the TLWP with the following noted exceptions:

1. During TLWP implementation, AoE-4 (i.e., NG Area – Former Ponds) contained standing water and therefore prohibited terrestrial investigation. AoE-4 is known to be a transitional habitat (terrestrial and aquatic depending on the time of year, seasonal rainfall, etc.). Due to the inaccessibility of the area and the known high lead concentrations in soil and sediment, NG Area – Former Ponds was designated as an Area of Presumed Remedial Action (APRA; **Appendix B**) and does not require additional investigation as part of the TLWP.

2. Although eight step-out locations were proposed around each primary sample location, a total of six step-out locations were inaccessible due to field conditions (e.g., concrete piles, uneven terrain, vegetation) and therefore not sampled. The total number of step-out

samples taken around each primary sample location is shown in the in-text table above and sample locations are presented in **Figures D.1** through **D.3**.

D.5 Laboratory Analysis

Dried and sieved samples were screened for the presence of lead via X-ray fluorescence spectrophotometry (XRF) analysis. Samples selected for laboratory analysis based on XRF-screening results were then shipped to Eurofins Lancaster Laboratories Environmental (ELLE) consistent with procedures outlined in the TLWP. Soil sample locations selected for analysis based on XRF-screening were analyzed for the following:

- Lead via USEPA SW 846 Method 6020A
- pH via USEPA SW 846 Method 9040C
- Total Organic Carbon (TOC) via USEPA SW 846 Method 5310C
- Grain size via ASTM International Method D422

Upon receipt of sample analytical results from ELLE, total lead results from laboratory confirmation samples were evaluated to identity samples on which to perform sequential extraction procedure (SEP) analysis. Samples with total lead concentrations less than site specific environmental screening criteria of 488 mg/kg were not considered for SEP analysis (**Attachment 8**). For remaining samples with total lead concentrations exceeding 488 mg/kg, three samples from each AoE were selected. The selected samples represent the maximum detected concentration, lowest concentration exceeding 488 mg/kg, and a sample nearest to the arithmetic average of those two samples. The sample selection process and rationale for SEP analysis are shown in **Table D.1.**

SEP reports the concentration of lead partitioned across seven fractions. Extractants are applied in a stepwise process so that each successive fraction obtained corresponds to trace lead associated with lesser mobility fractions. In general, this analysis provides detailed information about mobility and bioavailability of lead in solid samples to upper trophic level receptors.

Selected samples were shipped to TestAmerica in Knoxville, Tennessee for SEP analysis via USEPA 6010B. Analytical laboratory reports are provided in **Attachment D.1**.

D.6 Data Summary and Results

Table D.1 provides a results summary indicating good correlation between field XRF-screening results and confirmation samples analyzed for total lead via USEPA SW 846 Method 6020A.

Nineteen soil samples were submitted to ELLE for analysis of total lead, pH, TOC, and grain size. Associated analytical results are not incorporated into the ERA dataset as they represent areas of presumed remedial action (APRAs). However, results of SEP analysis (as discussed below) are incorporated into the ERA exposure assumptions of lead bioavailability.

General chemistry and total lead results of samples selected for SEP analyses are presented in **Table D.2** for reference. Laboratory data packages and confirmation of electronic data deliverable (EDD) submittals is included in **Attachment D.1**.

Interpretation of the SEP results relies on the following information about each step and the associated complexation/binding of lead.

Step 1 - Exchangeable Phase: This extraction includes trace elements that are reversibly sorbed to soil minerals, amorphous solids, and/or organic material by electrostatic forces.

Step 2 - Carbonate Phase: This extraction targets trace elements that are sorbed or otherwise bound to carbonate minerals.

Step 3 – Non-Crystalline Materials Phase: This extraction targets trace elements that are complexed by amorphous minerals (e.g. iron).

Step 4 - Metal Hydroxide Phase: Trace elements bound to hydroxides of iron, manganese, and/or aluminum.

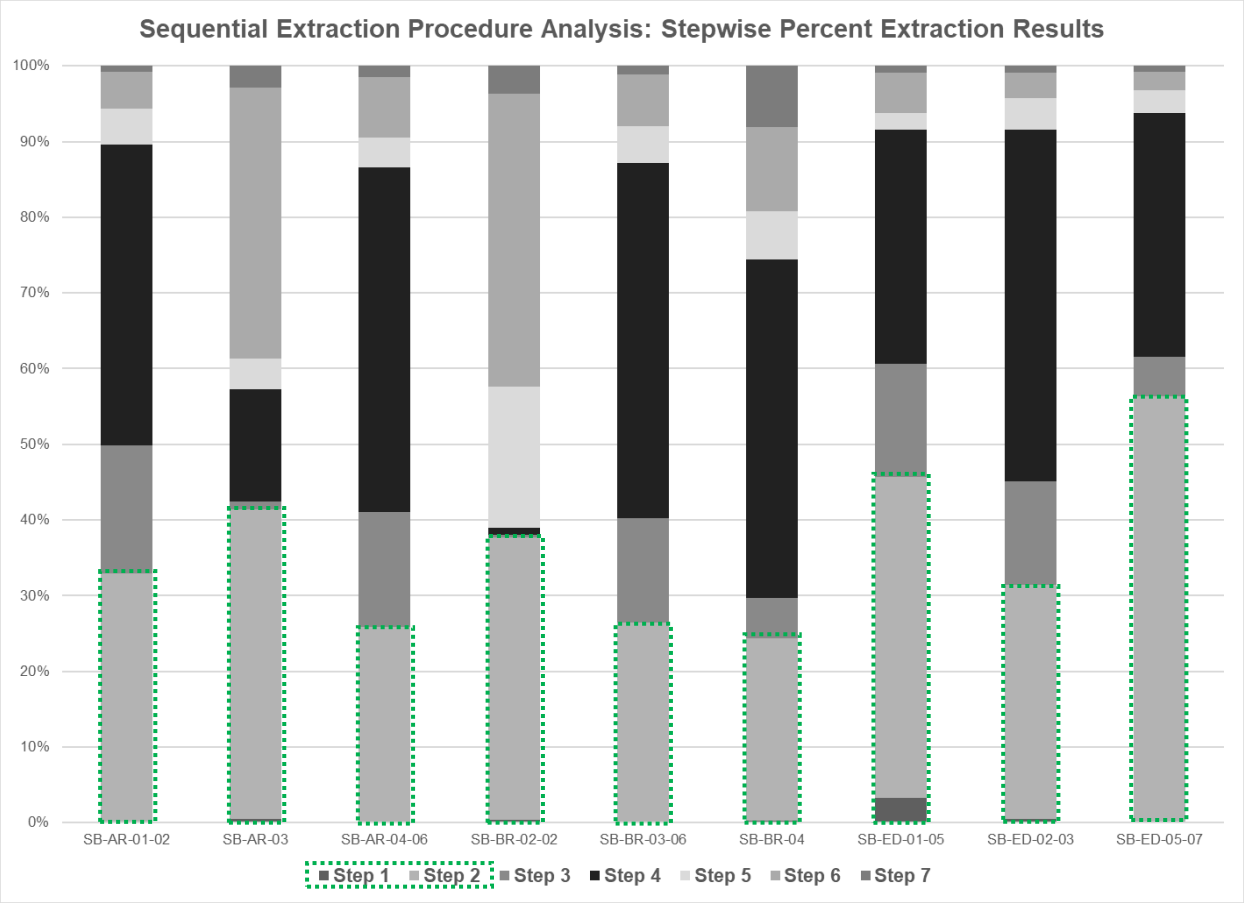
Step 5 - Organic Phase: This extraction targets trace elements strongly bound via chemisorption to organic material.

Step 6 - Acid/Sulfide Fraction: The extraction is used to identify trace elements precipitated as sulfide minerals.

Step 7 - Residual Fraction: Trace elements remaining in the soil after the previous extractions will be distributed between silicates, phosphates, and refractory oxides.

The chart below presents SEP analysis results broken down by stepwise percent extraction.

Table D.2 provides analytical results of SEP analysis. The chart below presents SEP analysis results broken down by stepwise percent extraction.



The fraction of total lead extracted in Steps 1 and 2 of SEP analysis represent the exchangeable and carbonate phases, respectively. The exchangeable phase is associated with the potentially bioavailable fraction where variations in soil chemistry can influence sorption and desorption. The carbonate phase represents a fraction where lead is associated with carbonates, whereby bioavailability and mobility are a function of pH. These two phases collectively comprise the weakly bound fraction of lead (Tessier et al. 1979) and are most readily bioavailable to ecological receptors. As such, results of SEP analysis indicate that 24 to 56% of total lead concentrations in soil are weakly bound and potentially bioavailable.

As presented in the following chart, percent bioavailable fractions were evaluated using Risk Assessment Code (RAC) classifications developed by Perin et al. (1985), where 1-10% indicates low risk, 11-30% indicates medium risk, 31-50% indicates high risk, and greater than 50% indicates very high risk. Results of SEP analysis and RAC classification indicate that areas within AoE-1, AoE-2, and AoE-3 are likely to present unacceptable risk to ecological receptors, driven by bioavailable fractions of total lead in soil, and merit remediation. Consistent with the Facility-specific approach (as detailed in Section 1.2 of the ERA), these AoEs are designated as APRAs and will not be proposed for terrestrial invertebrate tissue sampling in accordance with the TLWP or further evaluated in the ERA (**Appendix B**).

D.7 Lead Bioavailability in the Terrestrial Exposure Area

In the ERA terrestrial exposure area where the potential risk from lead is uncertain, potential risk to lower- and upper-trophic-level receptors were evaluated under three bioavailability assumptions (24, 56, and 100%) to illustrate the influence on soil direct contact exposure point concentrations (EPCs) and terrestrial food web modeling (as detailed below).

Terrestrial lead bioaccumulation factors (BAFs) are presented in **Table D.3**; the resulting estimated tissue concentrations of total lead and upper and lower bound bioavailable lead fractions are presented in **Table D.4**.

Table D.5 presents HQs based on maximum detected total lead concentrations and upper and lower bound bioavailable lead fractions and 95% upper confidence limit of the mean (95UCL) EPCs estimating potential risk to soil invertebrates. Based on the 95UCL, HQs for soil invertebrates are less than or equal to 1 under 24, 56, and 100% bioavailability assumptions.

Table D.6 presents HQs based on maximum detected total lead concentrations and upper and lower bound bioavailable lead fractions and 95UCL EPCs estimating potential risk to terrestrial plants. The following table summarizes terrestrial plant HQs greater than or equal to 1.

COPEC	Bioavailable Fraction (%)	Terrestrial Plants
		$HQ95_{UCL}$
Lead	24	≤1
	56	**3**
	100	**5**

Table D.7 presents selected exposure parameters for upper-trophic-level terrestrial receptor species. Potential ecological risk from total lead concentrations and upper and lower bound bioavailable lead fractions were evaluated for three avian receptors (**Tables D.7, D.8, and D.9**) and three mammalian receptors (**Tables D.10, D.11, and D.12**) in the terrestrial exposure area.

Table D.13 summarizes the no observed adverse effect level [NOAEL-] and lowest observed adverse effect level [LOAEL]-based HQs (HQ_{NOAELs} and HQ_{LOAELs}, respectively) for total lead and upper and lower bound bioavailable lead fractions. The following table summarizes upper-trophic-level terrestrial receptor HQs greater than or equal to 1.

COPEC	Bioavailable Fraction (%)	American Robin		Short-Tailed Shrew	
		HQ_{NOAEL}	HQ_{LOAEL}	HQ_{NOAEL}	HQ_{LOAEL}
Lead	24	**3**	**1**	≤1	≤1
	56	**5**	**3**	≤1	≤1
	100	**9**	**5**	**2**	≤1

Results of this comparative risk analysis are incorporated in terrestrial risk characterization in Section 7.1 of the ERA.

Notes:
a. USEPA 1993
b. Daily ingestion rates converted to dry weight assuming a moisture content of the following (USEPA 2007):
Invertebrates: 84%
Tissue: 68%
Plants: 85%
c. Beyer et al. 1994 (muskrat based on values for woodchuck; robin based on values for woodcock; bobwhite based on values for wild turkey)
d. USEPA 2007
e. Calculated by multiplying the soil ingestion rate times the dry weight daily ingestion rate.
% = percent
kg = kilogram
kg/day dw = kilogram per day dry weight
kg/day ww = kilogram per day wet weight
USEPA = United States Environmental Protection Agency

ANALYTICAL REPORT

Job Number: 140-13725-1

Job Description: Ashland - Kenvil Plant

Contract Number: No Number - No Expiration Date

For:
Kennedy/Jenks Consultants
214 Carnegie Center
Suite 103
Princeton, NJ 08540

Attention: Scott Larew

Approved for release.
Ryan Henry
Project Manager I
1/10/2019 4:16 PM

Ryan Henry, Project Manager I

Job Narrative
140-13725-1

Receipt
The samples were received on 12/19/2018 at 10:15am and arrived in good condition, properly preserved and, where required, on ice. The temperature of the cooler at receipt was 0.4° C.

Receipt Exceptions
Method(s) 9045D, Lloyd Kahn: The following samples were received outside of holding time: SB-ED-01-04 (00.0-00.5) (140-13725-1), SB-ED-01-05 (00.0-00.5) (140-13725-2), SB-ED-02-01 (00.0-00.5) (140-13725-3), SB-ED-02-03 (00.0-00.5) (140-13725-4), SB-ED-03 (00.0-00.5) (140-13725-5), SB-ED-04 (00.0-00.5) (140-13725-6), SB-ED-05-07 (00.0-00.5) (140-13725-7), SB-AR-01-02 (00.0-00.5) (140-13725-8), SB-AR-01-07 (00.0-00.5) (140-13725-9), SB-AR-02 (00.0-00.5) (140-13725-10), SB-AR-03 (00.0-00.5) (140-13725-11), SB-AR-04-03 (00.0-00.5) (140-13725-12), SB-AR-04-06 (00.0-00.5) (140-13725-13), SB-BR-02-02 (00.0-00.5) (140-13725-14), SB-BR-02-03 (00.0-00.5) (140-13725-15), SB-BR-03 (00.0-00.5) (140-13725-16), SB-BR-04 (00.0-00.5) (140-13725-17), SB-BR-04-06 (00.0-00.5) (140-13725-18), SB-BR-03-06 (00.0-00.5) (140-13725-19) and BD112718 (140-13725-20).

Metals
Method(s) 6020A: The method blank for preparation batch 680-552742 and analytical batch 680-553600 contained lead above the method detection limit (MDL). Associated sample(s) were not re-extracted and/or re-analyzed because results were greater than 10X the value found in the method blank.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

General Chemistry
Method(s) Lloyd Kahn: All of the samples were received outside of the 14 day holding time.

Method(s) 9045D: This analysis is normally performed in the field and has a method-defined holding time of 15 minutes. The samples have been qualified with the "HF" flag to indicate analysis was performed in the laboratory outside the 15 minute timeframe.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Qualifiers

Metals

Qualifier	Qualifier Description
B	Compound was found in the blank and sample.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

General Chemistry

Qualifier	Qualifier Description
H	Sample was prepped or analyzed beyond the specified holding time
HF	Field parameter with a holding time of 15 minutes. Test performed by laboratory at client's request.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
PQL	Practical Quantitation Limit
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)

The pound sign (#) in the amount added field denotes that the reagent was used undiluted. All calculations are performed using the stated concentration for this reagent.

METALS BATCH WORKSHEET

Lab Name: TestAmerica Savannah Job No.: 140-13725-1

SDG No.:

Batch Number: 552742 Batch Start Date: 12/21/18 07:50 Batch Analyst: Dixon, Charles D

Batch Method: 3050B Batch End Date: 12/27/18 12:31

Lab Sample ID	Client Sample ID	Method Chain	Basis	InitialAmount	FinalAmount	MS_Ag_LCS_SPK 00078	MS_LCS1_WK 00077	MS_LCS2_wk 00241	
140-13725-A-15	SB-BR-02-03 (00.0-00.5)	3050B, 6020A	T	1.15 g	500 mL				
140-13725-A-10	SB-AR-02 (00.0-00.5)	3050B, 6020A	T	1.19 g	500 mL				

Batch Notes	
Balance ID	27
Blank Soil Lot Number	5727510
Temperature - Corrected - End	95 Degrees C
Temperature - Corrected - Start	95 Degrees C
Digestion Unit ID	HB12
Digestion Tube/Cup ID	5831739
Hydrogen Peroxide ID	5691239
Hydrochloric Acid ID	5859877
Nitric Acid ID	5873968
Pipette/Syringe/Dispenser ID	ME16/ME22
Sufficient Volume for Batch QC	YES
Thermometer ID	MEPREP19
Temperature - Uncorrected - End	94 Degrees C
Temperature - Uncorrected - Start	94 Degrees C

Basis	Basis Description
T	Total/NA

The pound sign (#) in the amount added field denotes that the reagent was used undiluted. All calculations are performed using the stated concentration for this reagent.

The pound sign (#) in the amount added field denotes that the reagent was used undiluted. All calculations are performed using the stated concentration for this reagent.

GENERAL CHEMISTRY BATCH WORKSHEET

Lab Name: TestAmerica Savannah Job No.: 140-13725-1

SDG No.:

Batch Number: 552921 Batch Start Date: 12/22/18 10:07 Batch Analyst: Sharpe, Evan H

Batch Method: Moisture Batch End Date: 12/22/18 15:22

Batch Notes	
Balance ID	19
Date samples were placed in the oven	12/22/2018
Oven Temp In	108 Degrees C
Time samples were place in the oven	10:07
Date samples were removed from oven	12/22/2018
Oven Temp Out	101 Degrees C
Time Samples were removed from oven	15:22
Oven ID	CU01
Thermometer ID	EXTCLPWB1
Temperature - Start - Uncorrected	108 Degrees C
Temperature - End - Uncorrected	101 Degrees C

Basis	Basis Description
T	Total/NA

The pound sign (#) in the amount added field denotes that the reagent was used undiluted. All calculations are performed using the stated concentration for this reagent.

TESTAMERICA KNOXVILLE SAMPLE RECEIPT/CONDITION UPON RECEIPT ANOMALY CHECKLIST

Log In Number:

Review Items	Yes	No	NA	If No, what was the problem?
1. Are the shipping containers intact?	✓			☐ Containers, Broken
2. Were ambient air containers received intact?			✓	☐ Checked in lab
3. The coolers/containers custody seal if present, is it intact?			✓	☐ Yes ☐ NA
4. Is the cooler temperature within limits? (> freezing temp. of water to 6 °C, VOST: 10°C) Thermometer ID: SC68 Correction factor: 0	✓			☐ Cooler Out of Temp, Client Contacted, Proceed/Cancel ☐ Cooler Out of Temp, Same Day Receipt
5. Were all of the sample containers received intact?	✓			☐ Containers, Broken
6. Were samples received in appropriate containers?	✓			☐ Containers, Improper; Client Contacted; Proceed/Cancel
7. Do sample container labels match COC? (IDs, Dates, Times)	✓			☐ COC & Samples Do Not Match ☐ COC Incorrect/Incomplete ☐ COC Not Received
8. Were all of the samples listed on the COC received?	✓			☐ Sample Received, Not on COC ☐ Sample on COC, Not Received
9. Is the date/time of sample collection noted?	✓			☐ COC; No Date/Time; Client Contacted
10. Was the sampler identified on the COC?	✓			☐ Sampler Not Listed on COC
11. Is the client and project name/# identified?	✓			☐ COC Incorrect/Incomplete
12. Are tests/parameters listed for each sample?	✓			☐ COC No tests on COC
13. Is the matrix of the samples noted?	✓			☐ COC Incorrect/Incomplete
14. Was COC relinquished? (Signed/Dated/Timed)	✓			☐ COC Incorrect/Incomplete
15. Were samples received within holding time?	✓	/		☐ Holding Time - Receipt
16. Were samples received with correct chemical preservative (excluding Encore)?			/	☐ pH Adjusted, pH Included (See box 16A) ☐ Incorrect Preservative
17. Were VOA samples received without headspace?			/	☐ Headspace (VOA only)
18. Did you check for residual chlorine, if necessary? (e.g. 1613B, 1668) Chlorine test strip lot number:			/	☐ Residual Chlorine
19. For 1613B water samples is pH<9?			/	☐ If no, lab will adjust
20. For rad samples was sample activity info. Provided?			/	☐ Project missing info

Note: Since laboratory accreditations are subject to change, TestAmerica Laboratories, Inc. places the ownership of method, analyte & accreditation compliance upon out subcontract laboratories. This sample shipment is forwarded under chain-of-custody. If the laboratory does not currently maintain accreditation in the State of Origin listed above for analysis/tests/matrix being analyzed, the samples must be shipped back to the TestAmerica laboratory or other instructions will be provided. Any changes to accreditation status should be brought to TestAmerica Laboratories, Inc. attention immediately. If all requested accreditations are current to date, return the signed Chain of Custody attesting to said complicance to TestAmerica Laboratories, Inc.

Question	Answer	Comment
Radioactivity wasn't checked or is </= background as measured by a survey meter.	True	Lab does not accept radioactive samples.
The cooler's custody seal, if present, is intact.	True	729015
Sample custody seals, if present, are intact.	True	
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	
Cooler Temperature is recorded.	True	1.3ºC
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	N/A	Received project as a subcontract.
There are no discrepancies between the containers received and the COC.	True	
Samples are received within Holding Time (excluding tests with immediate HTs)	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	N/A	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
Containers requiring zero headspace have no headspace or bubble is <6mm (1/4").	N/A	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A

Definitions/Glossary

Client: Kennedy/Jenks Consultants
Project/Site: Ashland - Kenvil Plant SEP

TestAmerica Job ID: 140-13725-3

Qualifiers

Metals

Qualifier	Qualifier Description
*	LCS or LCSD is outside acceptance limits.
B	Compound was found in the blank and sample.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.
V	Serial Dilution exceeds the control limits

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
PQL	Practical Quantitation Limit
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)

Job Narrative
140-13725-3

Receipt
The samples were received on 12/19/2018 at 10:15am and released from On Hold on 01/29/19. They arrived in good condition, properly preserved and, where required, on ice. The temperature of the cooler at receipt was 0.4º C.

Metals
7 Step Sequential Extraction Procedure

These soil samples were prepared and analyzed using TestAmerica Knoxville standard operating procedure KNOX-MT-0008, "7 Step Sequential Extraction Procedure". SW-846 Method 6010B as incorporated in TestAmerica Knoxville standard operating procedure KNOX-MT-0007 was used to perform the final instrument analyses.

An aliquot of each sample was sequentially extracted using the steps listed below:

· Step 1 - Exchangeable Fraction: A 5 gram aliquot of sample was extracted with 25 mL of 1M magnesium sulfate (MgSO4), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 2 - Carbonate Fraction: The sample residue from step 1 was extracted with 25 mL of 1M sodium acetate/acetic acid (NaOAc/HOAc) at pH 5, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 3 - Non-crystalline Materials Fraction: The sample residue from step 2 was extracted with 25 mL of 0.2M ammonium oxalate (pH 3), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 4 - Metal Hydroxide Fraction: The sample residue from step 3 was extracted with 25 mL of 1M hydroxylamine hydrochloride solution in 25% v/v acetic acid, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 5 - Organic-bound Fraction: The sample residue from step 4 was extracted three times with 25 mL of 5% sodium hypochlorite (NaClO) at pH 9.5, centrifuged and filtered. The resulting leachates were combined and 5 mL were digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 6 - Acid/Sulfide Fraction: The sample residue from step 5 was extracted with 25 mL of a 3:1:2 v/v solution of HCl-HNO3-H2O, centrifuged and filtered. 5 mL of the resulting leachate was diluted to 50 mL with reagent water and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 7 - Residual Fraction: A 1.0 g aliquot of the sample residue from step 6 was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Results are reported in mg/kg on a dry weight basis.

In addition, a 1.0 g aliquot of the original sample was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Total metal results are reported in mg/kg on a dry weight basis.

Results were calculated using the following equation:

Result, µg/g or mg/Kg, dry weight = (C × V × V1 × D) / (W × S × V2)

Where:
C = Concentration from instrument readout, µg/mL
V = Final volume of digestate, mL
D = Instrument dilution factor
V1 = Total volume of leachate, mL
V2 = Volume of leachate digested, mL
W = Wet weight of sample, g
S = Percent solids/100

A method blank, laboratory control sample and laboratory control sample duplicate were prepared and analyzed with each SEP step in order to provide information about both the presence of elements of interest in the extraction solutions, and the recovery of elements of interest from the extraction solutions. Results outside of laboratory QC limits do not reflect out of control performance, but rather the effect of the extraction solution upon the analyte.

A laboratory sample duplicate was prepared and analyzed with each batch of samples in order to provide information regarding the reproducibility of the procedure.

SEP Report Notes:

The final report lists the results for each step, the result for the total digestion of the sample, and a sum of the results of steps 1 through 7 by element.

The digestates for steps 1, 2 and 5 were analyzed at a dilution due to instrument problems caused by the high solids content of the digestates. The reporting limits were adjusted accordingly.

Method(s) 6010B: The serial dilution performed for the following sample associated with batch 140-27848 was outside control limits: (140-13725-A-2-B SD ^10) Sample non-homogeneity suspected.

Method(s) 6010B: The following samples were diluted to bring the concentration of the target analyte, Lead, within the calibration range: SB-AR-03 (00.0-00.5) (140-13725-11) and SB-BR-02-02 (00.0-00.5) (140-13725-14). Elevated reporting limits (RLs) are provided.

Method(s) 6010B SEP: The serial dilution performed for the following sample associated with batch 140-27809 was outside control limits: (140-13725-A-2-X SD ^5) Sample non-homogeneity suspected.

Method(s) 6010B SEP: The following samples were diluted to bring the concentration of the target analyte, Lead, within the calibration range: SB-AR-03 (00.0-00.5) (140-13725-11) and SB-BR-02-02 (00.0-00.5) (140-13725-14). Elevated reporting limits (RLs) are provided.

Method(s) 6010B SEP: Samples were analyzed at 1:1 dilutions due to sample matrix and elemental interferences (Si, Al, Fe). As an additional note, titanium is not an interfering element for the lead line used to report the samples.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

General Chemistry
% Moisture: The samples were analyzed for percent moisture using SOP number KNOX-WC-0012 (based on Modified MCAWW 160.3 and SM2540B and on the percent moisture determinations described in methods 3540C and 3550B).

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

TESTAMERICA KNOXVILLE SAMPLE RECEIPT/CONDITION UPON RECEIPT ANOMALY CHECKLIST

Log In Number:

Review Items	Yes	No	NA	If No, what was the problem?
1. Are the shipping containers intact?	✓			☐ Containers, Broken
2. Were ambient air containers received intact?			✓	☐ Checked in lab
3. The coolers/containers custody seal if present, is it intact?			✓	☐ Yes ☐ NA
4. Is the cooler temperature within limits? (> freezing temp. of water to 6 °C, VOST: 10°C) Thermometer ID: SC68 Correction factor: 0	✓			☐ Cooler Out of Temp, Client Contacted, Proceed/Cancel ☐ Cooler Out of Temp, Same Day Receipt
5. Were all of the sample containers received intact?	✓			☐ Containers, Broken
6. Were samples received in appropriate containers?	✓			☐ Containers, Improper; Client Contacted; Proceed/Cancel
7. Do sample container labels match COC? (IDs, Dates, Times)	✓			☐ COC & Samples Do Not Match ☐ COC Incorrect/Incomplete ☐ COC Not Received
8. Were all of the samples listed on the COC received?	✓			☐ Sample Received, Not on COC ☐ Sample on COC, Not Received
9. Is the date/time of sample collection noted?	✓			☐ COC; No Date/Time; Client Contacted
10. Was the sampler identified on the COC?	✓			☐ Sampler Not Listed on COC
11. Is the client and project name/# identified?	✓			☐ COC Incorrect/Incomplete
12. Are tests/parameters listed for each sample?	✓			☐ COC No tests on COC
13. Is the matrix of the samples noted?	✓			☐ COC Incorrect/Incomplete
14. Was COC relinquished? (Signed/Dated/Timed)	✓			☐ COC Incorrect/Incomplete
15. Were samples received within holding time?	✓	/		☐ Holding Time - Receipt
16. Were samples received with correct chemical preservative (excluding Encore)?			/	☐ pH Adjusted, pH Included (See box 16A) ☐ Incorrect Preservative
17. Were VOA samples received without headspace?			/	☐ Headspace (VOA only)
18. Did you check for residual chlorine, if necessary? (e.g. 1613B, 1668) Chlorine test strip lot number:			/	☐ Residual Chlorine
19. For 1613B water samples is pH<9?			/	☐ If no, lab will adjust
20. For rad samples was sample activity info. Provided?			/	☐ Project missing info
