UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.2 7/28/2025 11:50:41 AM
From File	sediment_misc offsite streams lower
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

Aluminum

General Statistics

Total Number of Observations	4	Number of Distinct Observations	4
		Number of Missing Observations	15
Minimum	4910	Mean	7308
Maximum	9620	Median	7350
SD	2126	Std. Error of Mean	1063
Coefficient of Variation	0.291	Skewness	-0.0763

Note: Sample size is small (e.g., <10), if data are collected using incremental sampling methodology (ISM) approach, refer also to ITRC Tech Reg Guide on ISM (ITRC 2020 and ITRC 2012) for additional guidance, but note that ITRC may recommend the t-UCL or the Chebyshev UCL for small sample sizes (n < 7). The Chebyshev UCL often results in gross overestimates of the mean. Refer to the ProUCL 5.2 Technical Guide for a discussion of the Chebyshev UCL.

Normal GOF Test

Shapiro Wilk Test Statistic	0.96	**Shapiro Wilk GOF Test**	
1% Shapiro Wilk Critical Value	0.687	Data appear Normal at 1% Significance Level	
Lilliefors Test Statistic	0.206	**Lilliefors GOF Test**	
1% Lilliefors Critical Value	0.413	Data appear Normal at 1% Significance Level	

Data appear Normal at 1% Significance Level

Note GOF tests may be unreliable for small sample sizes

Assuming Normal Distribution

95% Normal UCL		**95% UCLs (Adjusted for Skewness)**	
95% Student's-t UCL	9809	95% Adjusted-CLT UCL (Chen-1995)	9013
		95% Modified-t UCL (Johnson-1978)	9803

Gamma GOF Test

A-D Test Statistic	0.266	**Anderson-Darling Gamma GOF Test**	
5% A-D Critical Value	0.657	Detected data appear Gamma Distributed at 5% Significance Level	
K-S Test Statistic	0.248	**Kolmogorov-Smirnov Gamma GOF Test**	
5% K-S Critical Value	0.395	Detected data appear Gamma Distributed at 5% Significance Level	

Detected data appear Gamma Distributed at 5% Significance Level

Note GOF tests may be unreliable for small sample sizes

Gamma Statistics

k hat (MLE)	15.07	k star (bias corrected MLE)	3.935
Theta hat (MLE)	484.8	Theta star (bias corrected MLE)	1857
nu hat (MLE)	120.6	nu star (bias corrected)	31.48
MLE Mean (bias corrected)	7308	MLE Sd (bias corrected)	3684
		Approximate Chi Square Value (0.05)	19.66
Adjusted Level of Significance	N/A	Adjusted Chi Square Value	N/A

Assuming Gamma Distribution

95% Approximate Gamma UCL	11701	95% Adjusted Gamma UCL	N/A

Lognormal GOF Test

Shapiro Wilk Test Statistic	0.956	**Shapiro Wilk Lognormal GOF Test**	
10% Shapiro Wilk Critical Value	0.792	Data appear Lognormal at 10% Significance Level	
Lilliefors Test Statistic	0.224	**Lilliefors Lognormal GOF Test**	
10% Lilliefors Critical Value	0.346	Data appear Lognormal at 10% Significance Level	

Data appear Lognormal at 10% Significance Level

Note GOF tests may be unreliable for small sample sizes

Lognormal Statistics

68				Minimum of Logged Data	8.499					Mean of logged Data	8.863	
69				Maximum of Logged Data	9.172					SD of logged Data	0.303	
70												
71				**Assuming Lognormal Distribution**								
72				95% H-UCL	12051					90% Chebyshev (MVUE) UCL	10614	
73				95% Chebyshev (MVUE) UCL	12110					97.5% Chebyshev (MVUE) UCL	14185	
74				99% Chebyshev (MVUE) UCL	18263							
75												
76				**Nonparametric Distribution Free UCL Statistics**								
77				**Data appear to follow a Discernible Distribution**								
78												
79				**Nonparametric Distribution Free UCLs**								
80				95% CLT UCL	9056					95% BCA Bootstrap UCL	N/A	
81				95% Standard Bootstrap UCL	N/A					95% Bootstrap-t UCL	N/A	
82				95% Hall's Bootstrap UCL	N/A					95% Percentile Bootstrap UCL	N/A	
83				90% Chebyshev(Mean, Sd) UCL	10497					95% Chebyshev(Mean, Sd) UCL	11942	
84				97.5% Chebyshev(Mean, Sd) UCL	13947					99% Chebyshev(Mean, Sd) UCL	17886	
85												
86				**Suggested UCL to Use**								
87				95% Student's-t UCL	9809							
88				**Recommended UCL exceeds the maximum observation**								
89												
90				Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.								
91				Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.								
92				However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.								
93												
94				**Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be**								
95				**reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.**

Mean (detects)	0.107		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.
For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

1173												
1174	Warning: Data set has only 3 Detected Values.											
1175	This is not enough to compute meaningful or reliable statistics and estimates.											
1176												
1177												
1178	Note: Sample size is small (e.g., <10), if data are collected using incremental sampling methodology (ISM) approach,											
1179	refer also to ITRC Tech Reg Guide on ISM (ITRC 2020 and ITRC 2012) for additional guidance,											
1180	but note that ITRC may recommend the t-UCL or the Chebyshev UCL for small sample sizes (n < 7).											
1181	The Chebyshev UCL often results in gross overestimates of the mean.											
1182	Refer to the ProUCL 5.2 Technical Guide for a discussion of the Chebyshev UCL.											
1183

Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Silver

General Statistics

Total Number of Observations	15	Number of Distinct Observations	14
		Number of Missing Observations	5
Number of Detects	1	Number of Non-Detects	14
Number of Distinct Detects	1	Number of Distinct Non-Detects	13

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!
It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Silver was not processed!

606					Maximum of Logged Data	5.468			SD of logged Data	0.36		
607												
608	**Assuming Lognormal Distribution**											
609					95% H-UCL	187.8			90% Chebyshev (MVUE) UCL	199.2		
610					95% Chebyshev (MVUE) UCL	219.1			97.5% Chebyshev (MVUE) UCL	246.8		
611					99% Chebyshev (MVUE) UCL	301.1						
612												
613	**Nonparametric Distribution Free UCL Statistics**											
614	**Data appear to follow a Discernible Distribution**											
615												
616	**Nonparametric Distribution Free UCLs**											
617					95% CLT UCL	175.8			95% BCA Bootstrap UCL	174.2		
618					95% Standard Bootstrap UCL	175.2			95% Bootstrap-t UCL	177.7		
619					95% Hall's Bootstrap UCL	176.3			95% Percentile Bootstrap UCL	175		
620					90% Chebyshev(Mean, Sd) UCL	193.3			95% Chebyshev(Mean, Sd) UCL	210.8		
621					97.5% Chebyshev(Mean, Sd) UCL	235.1			99% Chebyshev(Mean, Sd) UCL	283		
622												
623	**Suggested UCL to Use**											
624					95% Student's-t UCL	177.3						
625												
626	Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.											
627	Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.											
628	However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.											
629												
630	**Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be**											
631	**reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.**											
632												
633	**Benzo[a]anthracene**											
634												
635	**General Statistics**											
636					Total Number of Observations	3			Number of Distinct Observations	3		
637									Number of Missing Observations	4		
638					Number of Detects	1			Number of Non-Detects	2		
639					Number of Distinct Detects	1			Number of Distinct Non-Detects	2		
640												
641	**Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!**											
642	**It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).**											
643												
644	**The data set for variable Benzo[a]anthracene was not processed!**											
645												
646												
647	**Pyrene**											
648												
649	**General Statistics**											
650					Total Number of Observations	3			Number of Distinct Observations	3		
651									Number of Missing Observations	4		
652					Number of Detects	2			Number of Non-Detects	1		
653					Number of Distinct Detects	2			Number of Distinct Non-Detects	1		
654					Minimum Detect	74			Minimum Non-Detect	21		
655					Maximum Detect	240			Maximum Non-Detect	21		
656					Variance Detects	13778			Percent Non-Detects	33.33%		
657					Mean Detects	157			SD Detects	117.4

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.2 7/28/2025 11:55:56 AM
From File	sediment_maintenance ng area
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

RDX (Cyclonite)

General Statistics

Total Number of Observations	22	Number of Distinct Observations	19
		Number of Missing Observations	19
Number of Detects	0	Number of Non-Detects	22
Number of Distinct Detects	0	Number of Distinct Non-Detects	19

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!
Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!
The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable RDX (Cyclonite) was not processed!

Aluminum

General Statistics

Total Number of Observations	2	Number of Distinct Observations	2
		Number of Missing Observations	12
Minimum	5250	Mean	11625
Maximum	18000	Median	11625

Warning: This data set only has 2 observations!
Data set is too small to compute reliable and meaningful statistics and estimates!
The data set for variable Aluminum was not processed!

It is suggested to collect at least 8 to 10 observations before using these statistical methods!
If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Antimony

General Statistics

Total Number of Observations	3	Number of Distinct Observations	3
		Number of Missing Observations	11
Number of Detects	0	Number of Non-Detects	3
Number of Distinct Detects	0	Number of Distinct Non-Detects	3

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!
Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!
The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Antimony was not processed!

Arsenic

General Statistics

Total Number of Observations	22	Number of Distinct Observations	22
		Number of Missing Observations	19
Number of Detects	21	Number of Non-Detects	1
Number of Distinct Detects	21	Number of Distinct Non-Detects	1
Minimum Detect	2.05	Minimum Non-Detect	45.65
Maximum Detect	61.3	Maximum Non-Detect	45.65
Variance Detects	290.6	Percent Non-Detects	4.545%
Mean Detects	14.52	SD Detects	17.05

281	**Gamma ROS Statistics using Imputed Non-Detects**											
282	GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs											
283	GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)											
284	For such situations, GROS method may yield incorrect values of UCLs and BTVs											
285	This is especially true when the sample size is small.											
286	For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

2627					Detected Data appear Normal Distributed at 1% Significance Level							
2628												
2629					Suggested UCL to Use							
2630				95% KM (t) UCL	109.6							
2631												
2632					The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.							
2633					Please verify the data were collected from random locations.							
2634					If the data were collected using judgmental or other non-random methods,							
2635					then contact a statistician to correctly calculate UCLs.							
2636												
2637					Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.							
2638					Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.							
2639					However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.							
2640

Gamma GOF Tests on Detected Observations Only

A-D Test Statistic	0.394	**Anderson-Darling GOF Test**
5% A-D Critical Value	0.635	Detected data appear Gamma Distributed at 5% Significance Level
K-S Test Statistic	0.342	**Kolmogorov-Smirnov GOF**
5% K-S Critical Value	0.431	Detected data appear Gamma Distributed at 5% Significance Level

Detected Data Not Gamma Distributed at 5% Significance Level

Gamma Statistics on Detected Data Only

k hat (MLE)	20.28	k star (bias corrected MLE)	N/A
Theta hat (MLE)	52.26	Theta star (bias corrected MLE)	N/A
nu hat (MLE)	121.7	nu star (bias corrected)	N/A
Mean (detects)	1060		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	174.3

	A	B	C	D	E	F	G	H	I	J	K	L
403	GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs											
404	GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)											
405	For such situations, GROS method may yield incorrect values of UCLs and BTVs											
406	This is especially true when the sample size is small.											
407	For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Theta hat (MLE)	162.8	Theta star (bias corrected MLE)	190.9
nu hat (MLE)	10.64	nu star (bias corrected)	9.072
Mean (detects)	78.74		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free UCL Statistics		
Detected Data appear Gamma Distributed at 5% Significance Level		
Suggested UCL to Use		
95% KM Adjusted Gamma UCL	88.33	
The calculated UCLs are based on assumptions that the data were collected in a random and unbiased manner.		
Please verify the data were collected from random locations.		
If the data were collected using judgmental or other non-random methods,		
then contact a statistician to correctly calculate UCLs.		
Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.		
Recommendations are based upon data size, data distribution, and skewness using results from simulation studies.		
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Theta hat (MLE)	389.3	Theta star (bias corrected MLE)	410.9
nu hat (MLE)	18.37	nu star (bias corrected)	17.41
Mean (detects)	149		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	89.41

Gamma GOF Tests on Detected Observations Only

A-D Test Statistic	0.557	**Anderson-Darling GOF Test**
5% A-D Critical Value	0.766	Detected data appear Gamma Distributed at 5% Significance Level
K-S Test Statistic	0.292	**Kolmogorov-Smirnov GOF**
5% K-S Critical Value	0.331	Detected data appear Gamma Distributed at 5% Significance Level

Detected data appear Gamma Distributed at 5% Significance Level

Note GOF tests may be unreliable for small sample sizes

Gamma Statistics on Detected Data Only

k hat (MLE)	0.414	k star (bias corrected MLE)	0.332
Theta hat (MLE)	535.8	Theta star (bias corrected MLE)	668.5
nu hat (MLE)	5.795	nu star (bias corrected)	4.645
Mean (detects)	221.8		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	141.1
Maximum	1030	Median	13.5

A-D Test Statistic	0.453	**Anderson-Darling GOF Test**
5% A-D Critical Value	0.773	Detected data appear Gamma Distributed at 5% Significance Level
K-S Test Statistic	0.135	**Kolmogorov-Smirnov GOF**
5% K-S Critical Value	0.17	Detected data appear Gamma Distributed at 5% Significance Level

Detected data appear Gamma Distributed at 5% Significance Level

Gamma Statistics on Detected Data Only

k hat (MLE)	1.05	k star (bias corrected MLE)	0.961
Theta hat (MLE)	34.42	Theta star (bias corrected MLE)	37.6
nu hat (MLE)	58.81	nu star (bias corrected)	53.84
Mean (detects)	36.15		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	24.69
Maximum	215	Median	11.3
SD	39.67	CV	1.607
k hat (MLE)	0.271	k star (bias corrected MLE)	0.267

Skewness Detects	2.081	Kurtosis Detects	4.38
Mean of Logged Detects	2.632	SD of Logged Detects	1.553

Note: Sample size is small (e.g., <10), if data are collected using incremental sampling methodology (ISM) approach,
refer also to ITRC Tech Reg Guide on ISM (ITRC 2020 and ITRC 2012) for additional guidance,
but note that ITRC may recommend the t-UCL or the Chebyshev UCL for small sample sizes (n < 7).
The Chebyshev UCL often results in gross overestimates of the mean.
Refer to the ProUCL 5.2 Technical Guide for a discussion of the Chebyshev UCL.

Normal GOF Test on Detects Only

UCL Statistics for Data Sets with Non-Detects

User Selected Options	
Date/Time of Computation	ProUCL 5.2 8/7/2025 1:16:43 PM
From File	SW Unnamed Ponds
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

Aluminum

General Statistics

Total Number of Observations	7	Number of Distinct Observations	7
		Number of Missing Observations	13
Minimum	168	Mean	2234
Maximum	12300	Median	605
SD	4451	Std. Error of Mean	1682
Coefficient of Variation	1.992	Skewness	2.616

Note: Sample size is small (e.g., <10), if data are collected using incremental sampling methodology (ISM) approach, refer also to ITRC Tech Reg Guide on ISM (ITRC 2020 and ITRC 2012) for additional guidance, but note that ITRC may recommend the t-UCL or the Chebyshev UCL for small sample sizes (n < 7). The Chebyshev UCL often results in gross overestimates of the mean. Refer to the ProUCL 5.2 Technical Guide for a discussion of the Chebyshev UCL.

Normal GOF Test

Shapiro Wilk Test Statistic	0.523	**Shapiro Wilk GOF Test**
1% Shapiro Wilk Critical Value	0.73	Data Not Normal at 1% Significance Level
Lilliefors Test Statistic	0.464	**Lilliefors GOF Test**
1% Lilliefors Critical Value	0.35	Data Not Normal at 1% Significance Level

Data Not Normal at 1% Significance Level

Assuming Normal Distribution

95% Normal UCL		**95% UCLs (Adjusted for Skewness)**	
95% Student's-t UCL	5503	95% Adjusted-CLT UCL (Chen-1995)	6778
		95% Modified-t UCL (Johnson-1978)	5780

Gamma GOF Test

300					General Statistics						
301				Total Number of Observations	7					Number of Distinct Observations	7
302										Number of Missing Observations	13
303				Minimum	87.7					Mean	384.2
304				Maximum	1320					Median	275
305				SD	424.5					Std. Error of Mean	160.5
306				Coefficient of Variation	1.105					Skewness	2.345
307											
308				Note: Sample size is small (e.g., <10), if data are collected using incremental sampling methodology (ISM) approach,							
309				refer also to ITRC Tech Reg Guide on ISM (ITRC 2020 and ITRC 2012) for additional guidance,							
310				but note that ITRC may recommend the t-UCL or the Chebyshev UCL for small sample sizes (n < 7).							
311				The Chebyshev UCL often results in gross overestimates of the mean.							
312				Refer to the ProUCL 5.2 Technical Guide for a discussion of the Chebyshev UCL.

5% K-S Critical Value	0.302	Detected Data Not Gamma Distributed at 5% Significance Level

Detected Data Not Gamma Distributed at 5% Significance Level

Gamma Statistics on Detected Data Only

k hat (MLE)	0.975	k star (bias corrected MLE)	0.693
Theta hat (MLE)	1309	Theta star (bias corrected MLE)	1843
nu hat (MLE)	15.61	nu star (bias corrected)	11.09
Mean (detects)	1277		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	928.6
Maximum	3120	Median	357
SD	1251	CV	1.347

Spatial Analysis of Lead and Copper – Back Calculated EPCs

Appendix G
Spatial Analysis of Lead and Copper - Back-Calculated EPCs
Hercules LLC Kenvil Works Facility
Kenvil, NJ

Chemical	Body Weight (kg)	Dietary Composition		BAF_{invert}	BAF_{plant}	C_{invert} (mg/kg)	C_{plant} (mg/kg)	Daily Ingestion Rate (kg/day)	Soil Ingestion Rate (kg/day)	AUF	Daily Dietary Dose (mg/kg/d)	Soil Bioaccessible Fraction	Worm Bioccessible Fraction	TRV (mg/kg-d)	EPC (mg/kg)	HQ
		Inverts	Plants											LOAEL		LOAEL
Copper	0.081	37.5%	62.5%	0.515*(Cinvert)	e^(0.394*LN(Cplant)+0.668)	160.70	18.74	0.016	0.003	0.67	11.3	0.53	0.73	11.3	**312**	1
Lead	0.081	37.5%	62.5%	e^(0.807 * LN(Cinvert) - 0.218)	e^(0.561 * LN(Cplant) - 1.328)	118.73	8.54	0.016	0.003	0.67	11.3	0.53	0.73	11.3	**488**	1

Notes:
Based on the American Robin model
Equation:

$$EPC = \frac{HQ_{LOAEL} \times TRV \times BW}{AUF \times \left(IRsed + \left[IRfood \times \left[\left(BAF_{invert} \times \%diet\right) + \left(BAF_{plant} \times \%\, diet\right)\right]\right]\right)}$$

EPC = exposure point concentration
TRV = toxicity reference value
BW = body weight (kg)
AUF = area use factor
IRsed = Sediment Ingestion Rate (kg/day)
IRfood = Daily Ingestion Rate (kg/day)
BAF = Bioaccumulation Factor
%diet = Dietary Composition

Executive Summary

Hercules Incorporated (Hercules) prepared this Ecological Evaluation/Ecological Risk Assessment (EE/ERA) as a component of the Remedial Investigation Report for the former Hercules Kenvil Works Facility, located on Hercules Road in Kenvil, Morris County, New Jersey (the Facility). The remedial program at the Facility is coordinated through a licensed site remediation professional and conducted in accordance with the New Jersey Department of Environmental Protection's (NJDEP's) Technical Requirements for Site Remediation, New Jersey Administrative Code (N.J.A.C.) 7:26E. This ERA was prepared in accordance with N.J.A.C. 7:26E-4.8 Remedial Investigation of Ecological Receptors, as well as the Ecological Evaluation Technical Guidance (NJDEP 2015).

Consistent with NJDEP (2015), ecological investigation and assessment activities were conducted in accordance with United States Environmental Protection Agency (USEPA) and other federal guidance, including Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments (USEPA 1997). As specified in NJDEP and USEPA guidance, this ERA uses conservative assumptions related to potential exposures and receptors, and leverages Facility knowledge and associated remedial decision making processes to build upon the results of the site investigation (SI)/remedial investigation (RI).

The Facility occupies approximately 1,059 acres along Howard Boulevard, about 0.5 mile northwest of the center of Kenvil, in Morris County, New Jersey. The Facility began operation in 1871 and initially manufactured dynamite to support iron ore mining operations in the surrounding area. Through the early and middle parts of the 20th century, Hercules expanded its manufacturing operations to meet the growing economic need for explosives and propellants. In the final years of operation, smokeless powder was the primary product and was produced by Alliant under a lease agreement from 1995 to 1996. The facility ceased operation in 1996. Hercules, a wholly owned subsidiary of Ashland, Inc. and the current property owner, remains responsible for the remediation and closure of the Facility.

Data generated during the SI supported the establishment of the Remedial Area to focus RI activities within and immediately adjacent to the former manufacturing areas, and concluded that additional investigation of the outlying undeveloped portions of the Facility (those areas beyond the former manufacturing areas [beyond the Remedial Area]) was not warranted. This EE/ERA builds upon the information collected during characterization in the SI/RI phases and evaluates the potential for ecological risk

within the Remedial Area. A review of SI/RI data and findings identified areas where historical operations (e.g., emplacement of historic fill, point source releases, process upsets, etc.) influenced environmental media within the Remedial Area. In these ways, the SI/RI informs and focuses this EE/ERA. This EE/ERA separates the Facility into three general categories:

- Areas where ecological risk is negligible.
- Areas where ecological risk is uncertain and assessment is needed.
- Areas where constituent concentrations and/or physical characteristics merit remediation (e.g., ecological risk likely), regardless of the outcome of the ecological risk assessment process (Areas of Presumed Remedial Action).

This approach focuses the EE/ERA on areas where risks may be present and does not confound the process by evaluating areas where risks are unlikely (undeveloped areas beyond the Remedial Area) or very likely (certain Areas of Presumed Remedial Action), or where proposed remedial actions will address any potential exposure risks (certain Areas of Presumed Remedial Action). Using this approach, the EE/ERA aims to identify areas of the Facility that may present unacceptable ecological risk and to provide a foundation on which to base additional focused ecological evaluation (if warranted).

Ecological exposures could potentially occur across a range of areas and habitats found at the Facility, including:

- Former operational areas consisting of grassland, shrub, and young forest habitat in various states of succession and interspersed with remnants of operational structures (e.g., concrete pads, buildings, rubble piles).
- Mature forest occurring along the periphery of the Facility along steep ridgelines and ridgetops.
- Aquatic habitat including unnamed tributaries, Shooting Pond, Duck Pond, and several isolated vernal pools. Tributaries consist of altered (e.g., channelized, bermed) natural features and man-made drainage ditches that, along with Shooting Pond and Duck Pond, managed stormwater during Facility operations.

- The majority of the former operational areas, which drain to a forested wetland complex at the southern end of the Facility (southern wetland complex) via a series of tributaries.

These habitats support the identification of exposure areas and associated terrestrial and aquatic receptor species. Specifically, exposure areas used in this EE/ERA include site-wide soil (terrestrial) and two aquatic exposure areas (Northern Drainage Area and Southern Drainage Area) aligned with surface water drainages at the Facility. Areas beyond the Remedial Area and Areas of Presumed Remedial Action are not considered in this EE/ERA.

Potential exposures were evaluated using a series of assessment endpoints (AEs) and measurement endpoints (MEs). MEs include direct comparison of constituent concentrations in environmental media to ecological screening benchmarks (ESBs) protective of lower-trophic-level receptors (e.g., invertebrates and plants), as well as dietary dose modeling of constituents into upper-trophic-level receptors. Using generic screening levels and assumptions on the bioavailability of constituents adds conservative uncertainty to the assessment. These evaluations generated hazard quotients (HQs), which are ratios based on exposure concentrations relative to toxicity reference values from the scientific literature. Lowest observed adverse effects level-(LOAEL-) and no observed adverse effects level-based HQs provide a bounded range of risk estimates for consideration. Acknowledging the conservative assumptions on which this ERA is based, consideration of the LOAEL-based HQ (HQ_{LOAEL}) is appropriate.

An interpretation of HQ values relative to each AE and ME follows:

- AE 1. Could direct contact with COPECs in Facility soil affect the structure, function, and/or survival of the terrestrial plant community?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to terrestrial plant communities by exposure to COPECs at the Facility are possible.

  – This conclusion is supported by the following ME:

    ✓ HQs resulting from a comparison of soil COPEC concentrations to ESBs protective of terrestrial plants were greater than 1 for 10 COPECs; HQs

ranged from 2 to 46, with the greatest potential for risk from the metals mercury (46)[1], chromium (23), and vanadium (19).

- *AE 2*. Could direct contact with COPECs in Facility soil affect the structure, function, and/or survival of the terrestrial invertebrate community?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to terrestrial invertebrate communities by exposure to COPECs at the Facility are unlikely.

  – This conclusion is supported by the following ME:

    ✓ HQs resulting from a comparison of soil COPEC concentrations to ESBs protective of terrestrial invertebrates are less than 1 for COPECs, with the exception of copper (3) manganese (6), vanadium (2), and zinc (2).

- *AE 3*. Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of herbivorous avian and mammal populations?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to herbivorous avian and mammal populations by exposure to COPECs at the Facility are unlikely.

  – This conclusion is supported by the following MEs:

    ✓ HQ_{LOAELs} for the northern bobwhite, an herbivorous bird, are less than 1.

    ✓ HQ_{LOAELs} for the white-tailed deer, an herbivorous mammal, are less than 1.

[1] Calculated HQs are presented in parentheses next to each COPEC to show magnitude of potential to cause adverse effects; in other words, the larger the number, the greater the likelihood that adverse effects are possible.

- *AE 4*. Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of insectivorous avian and mammal populations?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to insectivorous avian populations by exposure to COPECs at the Facility are possible, but adverse effects to mammal populations by exposure to COPECs at the Facility are unlikely.

  – This conclusion is supported by the following MEs:

    ✓ HQ_{LOAELs} for American robin, an insectivorous bird, are less than 1, with the exception of total polychlorinated biphenyls (PCBs; 3), copper (3), and lead (25).

    ✓ HQ_{LOAELs} for short-tailed shrew, an insectivorous mammal, are less than 1, with the exception of lead (3).

- *AE 5*. Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of carnivorous avian and mammal populations?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to carnivorous avian and mammal populations by exposure to COPECs at the Facility are unlikely.

  – This conclusion is supported by the following MEs:

    ✓ HQ_{LOAELs} for red-tailed hawk, a carnivorous bird, are less than or equal to 1.

    ✓ HQ_{LOAELs} for red fox, a carnivorous mammal, are less than 1.

- *AE 6*. Could direct contact with COPECs in sediment in each area affect the structure, function, and/or survival of the benthic invertebrate community?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to

benthic invertebrate communities by exposure to COPECs in the Northern Drainage Area and Southern Drainage Area are possible.

  – This conclusion is supported by the following MEs:

    ✓ HQs resulting from a comparison of Northern Drainage Area sediment COPEC concentrations to ESBs protective of benthic invertebrates are greater than 1 for 7 COPECs.

    ✓ HQs resulting from a comparison of Southern Drainage Area sediment COPEC concentrations to ESBs protective of benthic invertebrates are greater than 1 for 21 COPECs.

- AE 7. Could direct contact with COPECs in sediment in each area affect the survival and function of aquatic plant populations?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to aquatic plants in the Northern Drainage Area and Southern Drainage Area are possible but unlikely.

    – This conclusion is supported by the following MEs:

      ✓ HQs resulting from a comparison of Northern Drainage Area sediment COPEC concentrations to ESBs protective of terrestrial plants were greater than 1 for four COPECs; HQs ranged from 2 to 21, with the greatest potential for adverse effects from chromium.

      ✓ HQs resulting from a comparison of Southern Drainage Area sediment COPEC concentrations to ESBs protective of terrestrial plants were greater than 1 for 15 COPECs; HQs ranged from 2 to 38, with the greatest potential for adverse effects from lead.

- *AE 8*. Could direct contact with COPECs in surface water in each area affect the survival and reproduction of fish and aquatic invertebrate populations?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to fish

populations by exposure to COPECs in the Northern Drainage Area and Southern Drainage Area are possible, but unlikely.

– This conclusion is supported by the following MEs:

✓ HQs resulting from a comparison of Northern Drainage Area surface water COPEC concentrations (dissolved phase) to ESBs protective of fish and aquatic invertebrate populations are less than 1 for COPECs, with the exception of copper (3) and lead (4).

✓ HQs resulting from a comparison of Southern Drainage Area surface water COPEC concentrations (dissolved phase) to ESBs protective of fish populations were less than 1 for COPECs, with the exception of lead (3).

- *AE 9*. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of herbivorous avian and mammal populations?

– Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to herbivorous avian and mammal populations by exposure to COPECs in the Northern Drainage Area and Southern Drainage Area are possible, but unlikely.

– This conclusion is supported by the following MEs:

✓ Northern Drainage Area HQ_{LOAELs} for mallard duck, an herbivorous bird, are less than 1.

✓ Northern Drainage Area HQ_{LOAELs} for muskrat, an herbivorous mammal, are less than 1.

✓ Southern Drainage Area HQ_{LOAELs} for mallard duck, an herbivorous bird, are less than 1, with the exception of lead (2).

✓ Southern Drainage Area HQ_{LOAELs} for muskrat, an herbivorous mammal, are less than 1, with the exception of pyrene (2).

- *AE 10*. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of insectivorous avian and mammal populations?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to insectivorous avian and mammal populations by exposure to COPECs in both the Northern and Southern Drainage Areas are possible.

  – This conclusion is supported by the following MEs:

    ✓ Northern Drainage Area HQ_{LOAELs} for tree swallow, an insectivorous bird, are less than 1, with the exception of copper (7) and lead (10).

    ✓ Northern Drainage Area HQ_{LOAELs} for little brown bat, an insectivorous mammal, are less than or equal to 1, with the exception of copper (3).

    ✓ Southern Drainage Area HQ_{LOAELs} for tree swallow, an insectivorous bird, are less than 1, with the exception of fluoranthene (3), copper (4), lead (224), and selenium (2).

    ✓ Southern Drainage Area HQ_{LOAELs} for little brown bat, an insectivorous mammal, are less than or equal to 1, with the exception of fluoranthene (6), pyrene (3), copper (2) lead (26), and selenium (2).

- *AE 11*. Could food-chain transfer of COPECs in sediment in each area adversely affect reproductive success or survival of piscivorous avian and mammal populations?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to:

    ✓ Piscivorous avian and mammal populations by exposure to COPECs in the Northern Drainage Area are unlikely.

    ✓ Piscivorous avian populations by exposure to COPECs in the Southern Drainage Area are possible.

- ✓ Piscivorous mammal populations by exposure to COPECs in the Southern Drainage Area are unlikely.

– This conclusion is supported by the following MEs:

- ✓ Northern Drainage Area HQ_{LOAELs} for great blue heron, a piscivorous bird, are less than or equal to 1.

- ✓ Northern Drainage Area HQ_{LOAELs} for mink, a piscivorous mammal, are less than or equal to 1.

- ✓ Southern Drainage Area HQ_{LOAELs} for great blue heron, a piscivorous bird, are less than 1, with the exception of lead (24).

- ✓ Southern Drainage Area HQ_{LOAELs} for mink, a piscivorous mammal, are less than 1, with the exception of lead (8).

These are reasonable findings based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

Overall, the potential for ecological risks is low. The greatest potential for adverse effects is from lead. Upper-trophic-level receptors in terrestrial (i.e., American robin) and aquatic (i.e., tree swallow, great blue heron, and little brown bat) exposure areas exhibit elevated lead HQs (ranging from 3 [short-tailed shrew] to 227 [tree swallow in Southern Drainage Area]). These results are based on food web modeling that did not incorporate measures of lead bioavailability. Soil and sediment characteristics at the Facility allow for the sequestration and binding of metals, potentially reducing the fraction of lead available for uptake by receptors and reducing the potential for adverse effects. Based on the results presented in this EE/ERA and the uncertainty regarding bioavailability, additional ecological investigation and risk assessment activities at the Facility are warranted. Refinements to the conservative evaluation presented here, as well as recommendations for additional sampling are presented in an Ecological Risk Assessment Work Plan provided as an appendix to this report.

Ecological Evaluation/ Ecological Risk Assessment

Kenvil Works Facility
Kenvil, Morris County, New Jersey

1. Introduction

Hercules Incorporated (Hercules) prepared this draft Ecological Evaluation /Ecological Risk Assessment (EE/ERA) as a component of the Remedial Investigation Report (RIR) for the former Hercules Kenvil Works Facility, located on Hercules Road in Kenvil, Morris County, New Jersey (the Facility; Figure 1-1). The remedial program at the Facility is coordinated through a licensed site remediation professional (LSRP) and conducted in accordance with New Jersey Department of Environmental Protection's (NJDEP's) Technical Requirements for Site Remediation (TRSR), New Jersey Administrative Code (N.J.A.C.) 7:26E.

This EE/ERA was prepared in accordance with N.J.A.C. 7:26E-1.16 – Receptor Evaluation - Ecological and N.J.A.C. 7:26E-4.8 Remedial Investigation of Ecological Receptors, as well as the Ecological Evaluation Technical Guidance (NJDEP 2015); and fulfills the requirements set forth in both N.J.A.C. 7:26E subsections 1.16 and 4.8. Consistent with NJDEP (2015), ecological investigation and assessment activities were conducted in accordance with United States Environmental Protection Agency (USEPA) and other federal guidance, including Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments (USEPA 1997). Acknowledging the breadth and depth of site characterization data available, this document supplements the Ecological Evaluation with a quantitative ERA (including food web modeling) based on conservative assumptions. As such it fulfills both NJDEP and USEPA technical requirements for ecological evaluations and ecological risk assessments.

1.1 Sitewide Remedial Strategy

As part of the Remedial Agreement executed between Hercules and NJDEP in March 1995, a sitewide restoration strategy was developed to guide the investigation, remediation, and closure of the Facility. The strategy employs a phased approach whereby the focus of subsequent phases is tailored based on interpretation of information obtained during previous phase(s). The strategic approach considers both areal extent (i.e., entire Facility, former operational area, Area of Concern [AOC]) and media of interest (i.e., soil, groundwater, surface water, sediment) as appropriate. With the sitewide restoration strategy in place, Hercules initiated a Site Investigation (SI) in 1997.

The SI identified and investigated approximately 1,200 AOCs at the Facility, and created ten AOC groups based on similarities in historical operational function and/or

processes. The results of the SI effectively reduced the number of AOCs requiring additional investigation in the RI and generated data necessary to define the "Remedial Area," which encompasses the former operational areas of the Facility and those areas immediately adjacent to former operational areas influenced by Facility operations (Figure 1-2). This informed reductive approach aligns with the sitewide redevelopment strategy described in Section 3.2.3. Investigation in undeveloped areas (i.e., those areas of the Facility beyond the Remedial Area boundary) also occurred. Additional details regarding the SI can be found in Section 3.2.1.

Building upon SI findings, the RI provides spatial coverage within the Remedial Area and focused sampling within and proximate to potential source areas. The Phase I RIR (Hercules 2007) provided a comprehensive assessment of conditions onsite and culminated in a conceptual site model (CSM) summarizing constituent sources, mechanisms of release and transport, and potential receptors. The Phase I RIR also identified data gaps necessary to affirm the RI conclusions and provide information necessary to support the remedial design process.

NJDEP reviewed the Phase I RIR and issued a November 2010 comment letter to Hercules. As required under NJDEP's new regulatory construct under the Site Remediation Reform Act, an LSRP assumed a regulatory oversight role for the project. The LSRP (Mark Foley, LSRP ID No. 575999) reviewed the administrative record, including the Phase I RIR and associated NJDEP comments, and approved a Phase II RI sampling plan to fill data gaps identified in the Phase I RIR and address NJDEP comments. Phase II RI field sampling occurred in 2013.

This document incorporates the findings of the Phase II RI activities and evaluated the comprehensive site characterization dataset (SI, Phase I RI, and Phase II RI) using the risk assessment framework.

1.2 Purpose and Objectives

This EE/ERA is a standalone volume of the Phase II RIR (Hercules 2016) that updates and supplements the Phase I RIR (Hercules 2007). This EE/ERA builds upon the findings presented in the media-specific RIRs for the Facility (i.e., soil, groundwater, surface water, and sediment), and utilizes nearly 20 years of accumulated knowledge regarding historical site operations and related chemical and physical influences at the Facility.

This EE/ERA develops a technical basis regarding whether exposure to COPECs related to former Facility operations could adversely affect flora or fauna that inhabit the site. It evaluates the potential for ecological risks using the same informed, reductive approach employed in the SI/RI and separates the Facility into three general categories:

- Undeveloped areas beyond the Remedial Area where the potential for ecological risk is assumed unlikely.

- Areas within the Remedial Area where constituent concentrations and/or physical characteristics merit remediation (e.g., the potential for ecological risk is likely), regardless of the outcome of the EE/ERA process (hereafter referred to as Areas of Presumed Remedial Action).

- Areas within the Remedial Area where the potential for ecological risk is uncertain.

The first two categories of areas represent locations where potential ecological risk is either unlikely or highly likely. These areas are discussed and considered separately, and are not included in the quantitative evaluation of ecological risk. This reductive approach focuses the EE/ERA on places where potential ecological risk is uncertain within the Remedial Area, and does not confound the process by evaluating locations where potential ecological risk is unlikely (undeveloped areas) or very likely (Areas of Presumed Remedial Action). Using this approach, this EE/ERA aims to identify areas of the Facility that may present unacceptable ecological risk and to provide a foundation on which to base decisions related to additional focused ecological evaluation and/or environmental remediation (if warranted).

The overall objectives of the EE/ERA are as follows:

- Evaluate and present data and additional information from scientific resources to characterize ecological structure and function at the Facility.

- Describe potential ecological effects that may occur due to receptor exposure to COPECs.

- Estimate the extent of wildlife receptor exposure to COPECs.

- Characterize potential risks to wildlife receptors that may be exposed to COPECs.

- Describe uncertainty associated with the data evaluation, exposure assessment, effects evaluation, and risk characterization.

- Provide multiple lines of evidence to support a scientifically based risk management decision regarding the need for further ecological evaluation at the Facility.

Per NJDEP and USEPA guidance, this EE/ERA uses conservative assumptions related to potential exposures and receptors, and integrates Facility knowledge and associated remedial decision making processes to build upon the results of the SI/RI with a focus on ecological risk. The conclusions and recommendations of this EE/ERA focus additional ecological risk-related activities and/or remedial actions, where applicable.

1.3 Report Organization

The remainder of this EE/ERA is organized as follows:

- Section 2, Facility Overview, summarizes the physical location of the Facility and its ecological setting.

- Section 3, Problem Formulation, describes the environmental history of the Facility, constituent releases, ecological CSM, and selects measurement endpoints (MEs) and assessment endpoints (AEs).

- Section 4, Data Review and COPEC Selection, describes data usability, the dataset used for the EE/ERA, and screens data against ecological benchmarks to identify COPECs.

- Section 5, Exposure Assessment, discusses the selection of representative receptor species and exposure parameters used for food web modeling and presents the methodology of the food web modeling.

- Section 6, Effects Characterization, presents toxicity reference values (TRVs) for each COPEC.

- Section 7, Risk Characterization, presents results of the EE/ERA, including hazard quotients (HQs) resulting from food web models.

- Section 8, Uncertainty Analysis, discusses specific uncertainties and their associated effects on the outcome of the EE/ERA.

- Section 9, Conclusions and Recommendations, summarizes the results of the risk assessment process, including an evaluation of MEs and AEs, and provides multiple lines of evidence to support a scientifically-based risk management decision regarding the need for further ecological evaluation at the Facility.

- Section 10, References, lists the references used to develop this EE/ERA.

Tables, figures, appendices, and attachments support the text and are referenced accordingly.

2. Facility Overview

2.1 Location

The Facility occupies approximately 1,059 acres along Howard Boulevard, about 0.5 mile northwest of the center of Kenvil, Morris County, New Jersey (Figure 1-1). Regionally, the Facility is approximately 40 miles west of New York City and 30 miles east of the Delaware Water Gap. The Facility is bounded by the New Jersey Transit Railway to the north, Berkshire Valley Road to the southeast, Route 46 to the south, and Howard Boulevard to the northwest. Figure 2-1 presents a Site Plan with major topographic features.

2.2 Development and Operations

The Facility began operation in 1871 and initially manufactured dynamite to support iron ore mining operations in the surrounding area. The facility was operated by various companies until 1912, when Hercules became the sole owner. Through the early and middle parts of the 20th century, Hercules expanded its manufacturing operations to meet the growing economic need for explosives and propellants. During this period, multiple operational areas were established, as described in Section 3.2.1.

Propellants and explosive and energetic (E&E) compounds, such as 2,4,6-trinitrotoluene (TNT), nitroglycerin (NG), pentaerythritol tetranitrate (PETN), smokeless powder, and ammonium nitrate fuel oil (ANFO), were produced for both military and commercial applications. Specialty products such as initiating materials, ingredients for medical applications, and materials for actuating devices were also produced. In the final years of operation, smokeless powder was the primary product, and was produced by Alliant under a site lease agreement from 1995 to 1996.

The facility ceased operation in 1996. At this time Alliant Tech Systems operated the Facility, and Hercules entered into a voluntary agreement with the State of New Jersey to investigate the TNT Area. Hercules reacquired control of the Facility on January 1, 1997 and, as the property owner, remained responsible for remediation and closure of the Facility. Hercules, and its related environmental liabilities at the Facility, was acquired by Ashland, Inc. in 1996. Hercules currently operates as a wholly owned subsidiary of Ashland, Inc. and is responsible for remediating the Facility.

2.3 Regional Ecology

The Facility is located in the New Jersey Highlands physiographic province of north-central New Jersey and is characterized by broad, elevated ridges separated by long, narrow valleys. In general, topographic features in this region (e.g., ridges and valleys) tend to be oriented in a southwest to northeast direction.

Preserved land, primarily upland deciduous forest (dry mesic mixed oak forest [Karlin 1989]), is relatively abundant near the Facility. Rock outcrops, forested wetland mosaics, and stream channels intersperse among the expanses of upland forest. Open space includes the Berkshire Valley Wildlife Management Area, Mahlon-Dickerson Reservation, Allamuchy State Park, and other smaller parcels. Dense commercial and residential development and major infrastructure routes (e.g., railroads and highways) fragment other areas of forest habitat into smaller isolated patches.

The area currently known as Morris County was subject to repeated glaciation. Glacial lakes of varying sizes (e.g., Longwood Lake, Lake Hopatcong) occur in areas around the Facility. The glaciers scoured the northern part of the county to bare rock in places, deposited glacially mixed till, transported material over the county, and altered drainage patterns. Included within the formerly glaciated areas are numerous kettles, or basins. These kettles were filled progressively as organic material and mineral sediment accumulated in them. These features occur in the northeastern portion of the Facility (Natural Resources Conservation Service 1976).

Roxbury Township and Morris County support light industrial/commercial development. Originally settled in the early 1700s, Morris County became a national leader in iron ore mining following the Revolutionary War. By the late 1800s, the county produced more than ½ million tons of iron ore and relied on forests to provide wood and the vast network of flowing streams to power the mills and forges. By the early 1900s, the mining industry moved toward the Great Lakes region and the county became a suburban center for New York City (http://www.co.morris.nj.us/history/history.asp). Consequently, this dynamic development history altered the landscape, ecology, and hydrology. Mapping and assessment (at the HUC-14 level) conducted by the New Jersey Highlands Council identifies the effect of these changes on the Facility's subwatershed, and others in the surrounding area, by assigning a low resource value (NJDEP 2005).

2.4 Facility-Specific Ecology

The Facility is situated on a valley floor between two forested ridgelines. The former Facility operational areas remain vacant following decommissioning and demolition activities conducted between 1996 and 2003. These areas are in various states of vegetation succession and currently exist primarily as grass field and shrublands, interspersed with remnant infrastructure and building remains. Beyond these forested ridgelines, the Facility is flanked by transit routes (I-80, New Jersey Transit railroad), state and county roads (Route 46, Berkshire Valley Road, Howard Boulevard), and a mixture of commercial and residential development.

Transit corridors and development adjacent to the Facility create ecological breaks, separating the Facility from other natural areas nearby. Smaller ecological receptor species are unlikely to cross these ecological breaks and thus exist at the Facility in the capacity that the Facility is capable of supporting them. Given the size of the Facility and range of habitat and forage sources it provides, the Facility likely supports populations of smaller receptor species. Larger, upper-trophic-level species are less restricted by these ecological breaks, particularly avian species that cover large areas to forage and/or breed. The Facility security fence may inhibit the movement of terrestrial species between these areas of adjacent habitat and the Facility. However, signs of movement over and through the fence have been observed, indicating that some local migration occurs.

Hydrologic inputs at the Facility consist of precipitation, surface water features, stormwater from adjacent developed areas, and other flow conveyed by natural, altered, and man-made features. Remnants of the stormwater management systems in place during historical Facility operations serve to drain and convey stormwater onsite. The area north of Powder Mill Road near the construction and demolition debris landfill (C&D landfill) serves as a general topographic and flow divide. Water entering the Facility via streams, runoff, and stormwater outfalls south of the C&D landfill is conveyed through a series of culverts and ditches to the wetland complex at the southern end of the Facility. Duck Pond (and vernal pools to a lesser extent) serves as the collection point for sources of hydrology north and east of the divide, including a series of wetlands and tributaries draining directly to Duck Pond.

2.5 Threatened and Endangered Species

A February 2014 search of the New Jersey Natural Heritage Database identified records of the following state or federal threatened and endangered (T&E) species, or their habitat, at the Facility:

- Red-shouldered hawk (*Buteo lineatus* [state endangered])
- Arogos skipper butterfly (*Atrytone arogos arogos* [state endangered])
- Bobcat (*Lynx rufus* [state endangered]).

According to the database, Downy phlox (*Phlox polisa var. pilosa* [state endangered plant]) was identified onsite in 1937. Downy phlox has not been observed during various ecological surveys conducted at the Facility between 2010 and 2014.

In addition to the records onsite, search results identified records of the following T&E species or their habitat within 0.25 mile of the Facility:

- Barred owl (*Strix varia* [state threatened])
- Indiana bat (*Myotis sodalis* [federally threatened, state endangered])
- Bog turtle (*Glyptemys muhlenbergii* [federally threatened, state endangered])
- Wood turtle (*Glyptemys insculpta* [state threatened]).

Attachment 1 provides the New Jersey Natural Heritage Database search results.

Information provided by the New Jersey Natural Heritage Program relies on records of documented occurrences and information contained in the NJDEP Landscape Project mapping. The Landscape Project mapping uses buffers representative of foraging ranges or other species-specific behaviors (e.g., migration) and mapped habitat types to develop areas considered potential habitat for the species in question.

None of the T&E species listed as possibly present on or near the Facility have been identified onsite. Hercules conducted a Phase I bog turtle survey in November 2014 as a component of an NJDEP – Division of Land Use Regulation freshwater wetlands general permit. The survey identified areas of potential bog turtle habitat onsite.

Habitats available onsite may be include in the home ranges of larger, mobile predators like the bobcat and red-shouldered hawk, however, species-specific surveys have not been conducted.

The Arogos skipper butterfly has not been observed onsite, nor has its host plant (little bluestem [*Schizachyrium scoparium*]). Nectar-producing plants associated with the Arogos skipper butterfly (milkweed [*Asclepias* spp.]) occur onsite. Given the historical absence of open grasslands onsite during operational years, and the temporary presence of grasslands onsite more recently as succession to shrublands occurs, the Facility is unlikely to provide critical habitat for this species.

Section 2.6 presents the results of a habitat characterization, including vegetative species composition data and wildlife observations.

2.6 Habitat Characterization

The characterization of onsite and adjacent habitats provides information to identify environmentally sensitive areas, refine potential exposure and migration pathways, and inform the selection of exposure areas and receptor species used in the exposure assessment.

Two general habitat types exist within the Remedial Area at the Facility: developed areas (former operational areas) and undeveloped areas (buffers between former operational areas and neighboring properties). Field surveys conducted on July 28, 29, and 30, 2010 characterized aquatic, terrestrial and wetland habitats and identified wildlife in these areas. In addition, data were collected from May through July 2011 during a Facility-wide wetlands assessment. The following information was collected in each habitat, as appropriate:

- Location and approximate boundaries
- Vegetative community structure and composition
- Hydrologic influences.

Designations were assigned to each identified habitat based on the Checklist for Ecological Assessment/Sampling, which is included in the Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments (USEPA 1997). Ecosystem type designations include the following: terrestrial wooded, terrestrial scrub/shrub, terrestrial open field, terrestrial miscellaneous, aquatic non-flowing, aquatic flowing, and wetlands.

The presence of wildlife was identified via individual sightings, audible calls, or visual observation of wildlife signs (e.g., tracks, nesting structures, scat, and den sites). Rocks, logs, and leaf litter were also temporarily overturned to look for wildlife, such as

amphibians, reptiles, and small mammals. Wildlife survey data (identification to lowest taxon, sighting type, notable observations) were recorded in a field log book and documented with digital photographs when possible.

2.6.1 Terrestrial Habitats

Terrestrial ecosystem type designations (USEPA 1997) identified onsite include terrestrial wooded, terrestrial scrub/shrub, terrestrial open field, and terrestrial miscellaneous habitats. When possible, habitats onsite were placed into more descriptive subgroups within each of the USEPA-designated ecosystem types (USEPA 1997).

Table 2-1 lists plant species identified in each terrestrial habitat, as well as their USFWS hydrophytic classification. Table 2-2 lists wildlife species observed within each habitat area. Figure 2-2 shows the location and approximate boundaries of each terrestrial habitat.

2.6.1.1 Terrestrial Wooded Areas

2.6.1.1.1 Upland Deciduous (Oak/Hickory) Forest

The dominant upland forest community at the Facility (and in northern New Jersey) is oak-hickory, which commonly consists of a variety of oak and hickory species and includes secondary hardwood species. Oak-hickory forest occupies undisturbed (undeveloped) upland areas of the Facility, including the ridges that form the north and south sides of the Facility and the glaciated uplands on the east end of the Facility. Dominant tree species include white oak (*Quercus alba*), red oak (*Quercus rubra*), chestnut oak (*Quercus prinus*), shagbark hickory (*Carya ovata*), and mockernut hickory (*Carya glabra*). Other overstory plant associates include black birch (*Betula lenta*) and American basswood (*Tilia americana*).

The understory consists of sassafras (*Sassafras albidum*) and oak saplings where present, but is primarily dominated by black huckleberry (*Gaylussacia baccata*), Japanese barberry (*Berberis thunbergii*), and hay-scented fern (*Dennstaedtia punctilobula*).

2.6.1.1.2 Mixed Hardwood Forests

Mixed hardwood forests are second growth plant communities that re-invade disturbed areas. This common plant community onsite occurs along the fringes of wetlands, in portions of the interior of the Facility where demolition occurred, at the base of the two

ridges along the fringe of the oak-hickory forests, and in the uplands near Berkshire Valley Road. Dominant overstory species include black cherry (*Prunus serotina*), black walnut (*Juglans nigra*), American elm (*Ulmus americana*), red maple (*Acer rubrum*), red oak, sassafras, and hackberry (*Celtis occidenfalis*). These areas experience over-browsing by deer and commonly have a sparse understory.

2.6.1.1.3 Red Pine Stands

Historically, red or Norway pine (*Pinus resinosa*) was planted as a shock- and sound-absorbing buffer between the operational areas at the Facility. These trees grow in dense stands within these buffer areas. Japanese barberry (*Berberis thunbergii*) and hay-scented fern (*Dennstaedtia punctilobula*) dominate the understory.

2.6.1.2 Terrestrial Scrub/Shrub and Terrestrial Open Field Areas

2.6.1.2.1 Disturbed Shrubland

Disturbed shrubland patches border coniferous habitats in the southwestern offsite areas, and intersperse within the NG and Dynamite Areas, offsite areas east of the AN Area, and along the central eastern and northeastern borders of the B-Line Area. Disturbed shrublands included sparse tree canopies proximate to the upland red pine forests and deciduous oak/hickory forests. The shrub-dominated habitat includes Japanese barberry (*Berberis thunbergii*), autumn olive (*Elaeagnus umbellate*), black huckleberry (*Gaylussacia baccata*), multiflora rose (*Rosa multiflora*), horse nettle (*Solanum carolinense*), common reed (*Phragmites australis*), and deer-tongue panicum (*Panicum clandestinum*).

2.6.1.2.2 Disturbed Grassland/Forb Complex

Open field species are adapted to invading disturbed areas that are left to revert to a natural condition. Disturbed grassland/forb complexes occur throughout the formerly developed areas of the Facility. Dominant species include orchard grass (*Dactylis glomerata*), switchgrass (*Panicum virgatum*), red top (*Agrostis alba*), big bluestem (*Andropogon gerardii*), fescue species (*Festuca* spp.), deer-tongue panicum, bluegrass species (*Poa* spp.), multiflora rose (*Rosa multiflora*), common dewberry (*Rubus flagellaris*), yarrow (*Achillea millefolium*), spotted knapweed (*Centaurea stoebe*), Queen Anne's lace (*Daucus carota*), daisy fleabane (*Erigoron annus*), butter-and-eggs (*Linaria vulgaris*), birds foot treefoil (*Lotus cornifulatus*), black medick (*Medicago lupulina*), plantain species (*Plantago* spp.), Partridge pea (*Chamaecrista fasciculata*),and American vetch (*Vicia americana*).

Common reed monocultures occur in a few disturbed upland areas within this complex.

2.6.1.3 Terrestrial Miscellaneous Areas – Landscaped Areas

Formerly developed areas of the Facility retain some of the landscape plantings established during the operational era. These plantings and other volunteer species grow in open soil areas near former buildings and along Facility roads. Typical plantings include Norway maple (*Acer platanoides*) and silver maple (*Acer saccharinum*). Volunteer species include red maple (*Acer rubrum*), black cherry (*Prunus serotina*), and black walnut (*Juglans nigra*).

2.6.2 Aquatic and Wetland Habitats

Aquatic and wetland habitats identified onsite include wetlands and aquatic flowing and nonflowing ecosystem type designations, as provided in the Checklist for Ecological Assessment/Sampling (USEPA 1997). Table 2-1 lists plant species found within wetland habitats, as well as their USFWS hydrophytic classification. It also lists wildlife species observed within aquatic and wetland habitats. Figure 2-2 shows the approximate boundaries of wetland and aquatic habitats onsite. Aquatic and wetland habitats are described below.

2.6.2.1 Wetlands

2.6.2.1.1 Forested Wetland

Patches of forested wetlands occur in the Dynamite Area, south of the Dynamite Area within the miscellaneous/offsite areas, and the northeastern-most part of the Facility. Forest wetland patches also occur within the B-Line Area southeast of Duck Pond, Development Area northwest of Duck Pond, and Northeast and Northwest Storage Areas.

This wetland type is dominated by broad-leaved deciduous tree species. Red maple (*Acer rubrum*) mixed hardwood wetlands occur along stream corridors and in broad depressions. Other tree species include blackgum (*Nyssa sylvatica*), pin oak (*Quercus palustris*), and swamp white oak (*Quercus bicolor*). Understory consists primarily of sweet pepperbush (*Clethra alnifolia*), spicebush (*Lindera benzion*), highbush blueberry (*Vaccinium corymbosum*), and arrowwood (*Viburnum denfatum*). Disturbed understory areas are dominated by dense stands of Japanese barberry (*Berberis thunbergii*).

Cinnamon fern (*Osmunda cinnamomea*), sensitive fern (*Onoclea sensibilis*), and tussock sedge (*Carex stricta*) occupy sunny openings in these plant communities.

Other areas are dominated by cattail (*Typha latifolia*) and/or soft stem bulrush (*Scirpus validus*).

2.6.2.1.2 Emergent Wetland

Emergent wetlands occur in areas of the Facility, including the Southern Maintenance Area, along the border of the NG and Dynamite Areas, sunny open areas of the Facility, some depressional areas formed during remedial activities, and open water fringe areas. Dominant emergent wetland species onsite include tussock sedge as well as a diversity of other sedge species (*Carex* spp.), cattails, several types of rushes (*Juncus* spp.), and flatsedges (*Cyperus* spp.).

Other emergent plant communities occur in the large open field areas of the Facility that have been disturbed by grading and filling for historical development. On the west side of the Facility, a network of drainage ditches connects to the stream corridor. Emergent plant communities have developed in these ditches and depressional areas. Typical species include various species of spirea (*Spirea* spp.), rush species (*Juncus* spp.), sedge species (*Carex* spp.), white snakeroot (*Eupatorium rugosum*, FACU-), cattail, reed canary grass (*Phalaris canariensis*), poison ivy (*Toxicodendron radicans*), and Japanese barberry (*Berberis thunbergii*). Some of these areas were also dominated by common reed.

2.6.2.2 Aquatic Flowing Areas

Aquatic flowing areas present onsite include:

- Unnamed tributary flowing through the Northwestern Development Area.
- Unnamed tributary system flowing from the Southern Maintenance Area south through the Dynamite Area and miscellaneous/offsite areas.

Figure 2-2 shows the location of aquatic flowing habitats. These areas are principally characterized as red maple- (*Acer rubrum*-) dominated forested wetland that transition to either mixed-hardwood or oak-hickory upland forest communities. In-stream habitats are described in Section 2.6.2.1.2.

2.6.2.3 Aquatic Non-flowing Areas

Duck Pond represents the largest aquatic feature onsite, and drains many of the wetlands and tributaries on the northern portion of the Facility. Duck Pond was created

as a farm pond during the Facility's pre-1870 agricultural period. Throughout the Facility's history as a manufacturing facility, Duck Pond has been bermed, diked, and otherwise altered. The northern and southern edges of the pond are moderately sloped, while the western edge rises gently to a depressional area historically used for the thermal destruction of off-spec and residual materials.

A smaller, man-made pond (Shooting Pond) occurs north of Duck Pond and serves as an intermediate drainage feature for some of the same tributaries that ultimately drain to Duck Pond. Shooting Pond is a 35-foot-deep, rectangular pond that was historically used to perform submerged detonation testing.

Emergent and submerged aquatic species observed along the fringes of these open water bodies include spatterdock, fragrant lily (*Nymphaea odorata*), waterweed (*Elodea* spp.), spikerush (*Eleocharis* spp.), and watershield (*Brasenia schreberi*). River birch (*Betula nigra*), black willow (*Salix nigra*), and eastern cottonwood (*Populus deltoides*) are also located along the pond edges.

2.6.3 Habitat Characterization Summary

In summary:

- Former operational areas of the Facility consist of grassland, shrub, and young forest habitat in various states of secondary succession, interspersed with remnants of operational structures (e.g., concrete pads, buildings, rubble piles).

- Mature forest occurs along the periphery of the Facility along steep ridgelines and ridgetops.

- Aquatic habitat includes unnamed tributaries, Shooting Pond, Duck Pond, and several isolated vernal pools. The tributaries consist of altered (e.g., channelized, bermed) natural features and man-made drainage ditches that, along with Shooting Pond and Duck Pond, managed stormwater during Facility operations.

- The majority of the former operational areas of the Facility drain to a forested wetland complex at the southern end of the Facility via a series of tributaries.

These habitat characterization findings, as well as general observations during time spent onsite, support the development of exposure areas and associated terrestrial and aquatic receptor species.

3. Problem Formulation

Problem formulation, the first step in the EE/ERA, presents the environmental history of the Facility, develops the ecological CSM, and identifies assessment and measurement endpoints to focus the quantitative evaluation. The ecological CSM is built upon the Facility's environmental history and identifies environmental media containing Facility-related constituents, describes potential exposure pathways, and identifies potential ecological receptors.

3.1 Environmental History

Historically, the valley currently occupied by the Facility drained the neighboring ridgelines via a network of wetlands and streams. Development and expansion occurred periodically throughout the Facility history and made use of historic fill materials (e.g., fly ash, bottom ash, and slag derived from the combustion of coal), obtained primarily from offsite sources. Fill was used to raise ground surface elevations, provide a stable substrate for transportation and operational infrastructure (i.e., narrow gauge rail, roadways, buildings) and otherwise manage or direct surface water (i.e., stormwater runoff, historical drainage features).

Multiple production/operational areas supported former operations at the Facility (Figure 1-2). Initial operations involved the manufacture of dynamite (NG encased with absorptive filler material in a waxed paper shell) to support local iron ore mining. The original dynamite production area was located within a small section of the later developed NG, TNT, and Dynamite Areas identified on Figure 1-2. Portions of the later developed A-Line and Maintenance Areas were also used for finished product storage (A-Line) and maintenance activities (Maintenance Area).

Demand for E&E products increased during war time (beginning with World War I and continuing through the Vietnam War). In response, manufacturing operations expanded to encompass approximately 800 acres, including the PETN, A-Line, B-Line, ammonium nitrate (AN), Finishing, Storage, Development, and Diazo (diazodinitrophenol) Areas. Support areas were also developed, including office space, plant laboratories, maintenance areas, power houses, mixed acid areas, drum storage areas, the water supply system, a wastewater treatment plant, warehouses, and miscellaneous production and support buildings.

Figure 1-2 provides approximate boundaries for former operational areas of the Facility.

3.1.1 Environmental Releases

Environmental releases occurred during the operational history and during historic demolition practices (e.g. burning structures in place). Releases included accidents and/or incidents during production and transport of materials throughout the Facility as well as influences from historical practices onsite. Release mechanisms (e.g., fires, explosions, spills) and notable events are described below.

3.1.1.1 Fires

Historically, fires occurred as accidents and a means of intentionally decontaminating structures contaminated with E&E constituents or destroying off-specification E&E products. Uncontrolled fires resulting from accidents and production upsets were most frequent from 1871 until the 1950s when more advanced manufacturing process controls were incorporated. Though less common, fires have been documented as recently as 1989. Fires were of critical concern for the Facility as the nature of the E&E constituents manufactured released tremendous energy that could result in multiple operations becoming involved prior to the fire becoming controlled and eliminated.

Fires resulting from both accidents and intentional thermal decontamination efforts required the use of significant quantities of water. Accidental fires were contained and extinguished as soon as possible with as much water as could be directed toward the fire. Intentional thermal decontamination efforts required the use of significant quantities of water to ensure the fire did not spread beyond the intended structure. The water used had the potential to redistribute constituents either not consumed or affected by the fire creating localized heterogeneity of constituent distribution.

The use of fire as a means of thermally decontaminating structures with E&E constituents has long been an industry standard, and though minimized, continues to be used today. Typically, scrap wood or similar combustible material was placed into the structure in a manner so that all surfaces of the structure would be exposed to either direct flame or temperatures in excess of the thermal decomposition temperature of the E&E constituents manufactured. The fires would be allowed to burn until all combustible materials were consumed. It would be assumed that non-combustible materials (e.g. masonry and steel) were subjected to sufficient heat that thermal decomposition of E&E constituents was complete.

Thermal decontamination of structures containing residual E&E constituents is known to have been performed at the Facility in the past. However, following the 1996 closure

of the Facility approximately 300 structures that formerly supported E&E manufacturing were carefully demolished by personnel highly trained in E&E safety without using thermal decontamination.

Nearly all large E&E manufacturing facilities used open burning as a safe means of destroying off-specification E&E constituents. Due to the tremendous energy stored within the E&E constituents it has long been an industry standard dating back to at least the 1700s that intentional land disposal is not appropriate. Storing large quantities of off-specification E&E constituents also can be hazardous and was limited as much as possible. The use of open burning, though highly regulated, continues to this day in the industry. Typically, burning grounds were located a safe distance from manufacturing operations and in close proximity to a supply of water (i.e. ponds or fire hydrants).

In some instances it is possible that not all combustible constituents, including E&E, are consumed by fire. Small-scale detonations can occur if E&E constituents detonate at their thermal decomposition temperature of if they are confined with sufficient pressure. These small-scale detonations can cause the material to be thrown away from the fire and not be consumed. Additionally, constituents similar to TNT and DNT have high melting and decomposition temperatures and have the potential to migrate away from the fire in the molten state and recrystallize when temperatures drop below their melting point.

3.1.1.2 Explosions

Historically explosions at the Facility were not uncommon occurrences. In particular, during the World War I (WW I) era as many as 6,000 marginally trained and educated employees were imported from around the country to meet the rapidly increasing need for E&E constituents required to supply the United States (US) and its allies (Great Britain, France, and Russia). Other peak war time production eras (WW II, Korea, and Vietnam) also incorporated large untrained work forces into an ever increasing production demand. Correspondingly, an increase in explosions occurred.

In most cases explosions were limited to single operational units (e.g., C13 – 666 Refined TNT Graining House), and while very destructive were limited in their effect. The primary exception occurred in 1940 when approximately 300,000 pounds of smokeless gunpowder exploded at a single unit. This explosion led to secondary explosions in other operational areas caused by the shock wave and hot debris thrown by the force of the detonation. Ultimately, the 1940 explosion encompassed nearly the

entire manufacturing area of the Facility causing 51 deaths and more than 200 injuries. This was reportedly the worse explosive manufacturing facility disaster in U.S. history and caused the Facility to cease operations until it could be reconstructed.

Explosions resulted in disturbed ground surface, shattered structures, and scattered debris. Along with these direct effects, explosions also represent a potential means of constituent release and distribution. Other historic explosions while not as widespread nonetheless produce similar destruction on a lesser scale and permit constituents to enter the environment in an unregulated and heterogeneous manner.

Explosions have the ability to scatter debris and constituents associated with manufacturing operations over an often unpredictable area. In many cases the blast from an explosion is directionally biased due to engineering controls (i.e. earthen barricades) placed around the structures in an attempt to direct shock waves and hot debris away from other manufacturing structures containing E&E constituents in various stages of manufacture susceptible to possible ignition and/or detonation. Depending on the force of the explosion the engineering controls were variably effective, and in the case of the 1940 explosion ineffectual.

Due to limited historical information concerning the placement of engineering controls at previously existing structures and their effectiveness in the event of an explosion significant heterogeneity exists concerning the localized effects of constituent release. Additionally, it is possible that not all combustible constituents, including E&E, are consumed by explosions due to the force of the shock wave, as evidenced by the TNT still present at C13-666 (Refined TNT Graining House) that exploded during WW I. However, the localized heterogeneity of constituent distribution is not widespread and when evaluated from a Facility-wide perspective constituent distribution is well defined.

3.1.1.3 Spills

Throughout the than 125 years of manufacturing history at the Facility, general operations had the potential to release constituents to the environment through accidents (other than the more destructive fires and explosions previously discussed) or spillages on relatively small scales. As noted previously, peak war time production required a large, marginally trained workforce to meet the increased demand for E&E compounds; likely increasing the potential for accidents or spillages.

Accidents during transportation of raw and finished products have the greatest potential to release constituents to the environment. Transportation of raw and finished

products was accomplished through a variety of methods that included: mule-drawn buggies, human-drawn buggies (angel buggies), narrow gauge rail, and trucks. A small percentage of the accidents may have involved a release of the transported materials. Spillage of materials can occur for a variety of reasons that are often precipitated by either mechanical failure or inattentiveness. The following is a list of the primary reasons materials may have been spilled at the Facility:

- Transfer of materials
- Operation of machinery (e.g., mixers, packers, cutters, presses)
- Maintenance activities
- Mechanical failure.

It is believed many of the identified reasons associated with the potential to spill materials occurred within the manufacturing structure, significantly reducing the potential for the materials to enter the environment. Further, it was standard industry procedure to thoroughly clean up any spill involving E&E constituents, therefore, it is believed that primarily non-E&E constituents may be released in this manner.

It is possible that to a small degree some of the localized heterogeneity within the former operational areas of the Facility where material handling occurred could be attributed to the release of constituents by accidents and spills.

3.1.1.4 Historic Fill

The Facility began as a small operation in 1871 and solely produced dynamite to support the local iron mining industry. Manufacturing activities were limited to the southwestern area of the Facility in a small section of the current NG, TNT, and Dynamite Areas. Operations are believed to have been limited to the higher topography of the western ridge or immediately adjacent to the ridge where wet areas were not present. Portions of the A-Line and Maintenance Areas were also used in support roles such as finished product storage (A-Line) and maintenance activities (Maintenance Area). These areas were either located on the western ridge, adjacent to the western ridge, or on well drained elevated ground.

In the years leading up to and including World War I (WWI) the need for explosives and propellants increased dramatically and Hercules greatly expanded its manufacturing

operations. Prior to this expansion, it is believed surface elevations in many portions of the Facility were in close proximity to the water table and unsuitable for industrial development. Historic fill (consisting of fly ash, bottom ash, and slag derived from the combustion of coal) largely imported from off-site sources, was used to increase grade, eliminate shallow ponds/wet areas, improve drainage, and increase compatibility of the soils to allow construction of large manufacturing complexes. Historic fill was also used extensively for establishing both narrow gauge and standard gauge rail beds. In addition to rail beds, historic fill was used in some locations as part of the bridging support material used to allow narrow gauge rail lines to cross the numerous shallow streams located in the southwestern portion of the facility. Narrow gauge rail was the primary vehicular conveyance system at the Facility for more than 75 years and is substantially smaller than standard gauge rail. It can be moved or redirected quickly to meet changing operational needs. Due to the unknown historic topography of the Facility (e.g. location of former ponds/wet areas) and the locations of former narrow gauge rails that changed over time, the distribution of the historic fill is widespread and heterogeneously distributed across the Facility.

Hercules imported potentially large quantities of historic fill from local available sources that is believed to have possessed metal and PAH constituents prior to entering the Facility. The former iron foundries located in Dover, New Jersey, approximately four miles east of the Facility, are thought to have been the primary source of historic fill based on their location and extensive use of coal, although documentation of the source is not available.

Due to the very short period (1912 to 1914) of the large scale Facility expansion, other unknown sources of historic fill may have been secured. It is likely that historic fill from on-site Facility boilers[2] were added to the imported historic fill but represented a very small fraction of the total historic fill emplaced.

[2] The Facility is believed to have possessed a total of four powerhouse sites with associated coal-fired boilers that supported previous manufacturing operations. Prior to the large WWI expansion the powerhouses were relatively small (typically two boilers per powerhouse) and provided steam for areas immediately adjacent to the individual powerhouses. The small powerhouses were located in the Dynamite, NG, Storage, and Maintenance former operational areas. The Maintenance Area power house was divided into two structures, each believed to have two boilers. A total of ten small boilers are believed to have been present at the Facility prior to the WWI expansion. The exact dates of construction or operation of the four small power houses are not known but may have extended from the late 1800s through WWI (1919). Following WWI and after the major Facility expansion was complete the four small boilers were dismantled and replaced by a single large central powerhouse in the Maintenance Area that produced both steam and electricity.

3.2 Previous Investigations

Environmental investigations and actions were conducted onsite in response to releases during Facility operation and as part of the Industrial Site Recovery Act (ISRA) process initiated by the property transfer in 1996. The Phase I and Phase II RIRs (Hercules 2007, 2016) provide a comprehensive chronicle of environmental investigations conducted at the Facility. Findings from previous investigations pertinent to this EE/ERA are summarized below.

3.2.1 Site Investigation

In 1997, Hercules initiated an SI in response to the 1996 property transfer to fulfill ISRA requirements. The SI involved a Facility-wide evaluation of environmental media (soil, groundwater, surface water, and sediment) to identify if constituents were present in media onsite, and if present, present at concentrations greater than NJDEP remedial criteria at the time. As part of the process, the SI defined former operational areas of the Facility (Figure 1-2). Collectively, these former operational areas and certain areas immediately adjacent to them influenced by Facility operations form the Remedial Area. The SI also evaluated whether operations influenced undeveloped areas of the Facility (i.e., those areas beyond the Remedial Area). The SI identified negligible influences related to Facility operations in the undeveloped areas, with the exception of a few small, isolated areas that were subsequently included in the Remedial Area and evaluated in the RI. The remaining undeveloped areas of the Facility were not evaluated further during the RI.

The results of the SI focused the scope of the subsequent RI on refining the understanding of magnitude and extent, and delineating constituents in the Remedial Area. The Facility evaluation approach developed during the RI divided the Remedial Area into three distinct areas based on geographic location:

- *Area I – RI*. Areas north and east of Powder Mill Road (B-Line, Finishing, Storage, and Development [eastern portion] Areas, and portions of miscellaneous/offsite former operational areas).

- *Area II – RI*. Areas south and west of Mule Barn Road (NG, PETN, TNT, and Dynamite Areas, and portions of miscellaneous/offsite former operational areas).

- *Area III – RI*. Central portions of the Facility (A-Line, Maintenance, AN, Diazo, and Development [western portion] Areas, and portions of miscellaneous/offsite former operational areas).

Figure 1-2 shows the Facility boundary, Remedial Area, and former operational areas.

Beyond the general residual influences of historical operations identified during the RI, constituents in certain areas can be tied to specific incidents or releases documented in historical Facility records. For example, in 1917, the Refined TNT Graining House (C13-666) in the TNT Area was destroyed in an explosion (Hercules 2007). Sample results identified residual TNT in soil in the footprint of former buildings and in the surrounding area directly affected by the explosion.

As part of the data evaluation conducted for the RI and presented in this EE/ERA, constituent detections and concentrations that spatially correspond to documented incidents associated with the former operation of the Facility were identified. In certain cases, constituents are present at concentrations that merit evaluation in the remedial action selection process. Remedial actions conducted to date and additional actions pending design and implementation are summarized below.

3.2.2 Remedial Actions

Decommissioning and demolition of onsite structures occurred between 1996 and 2003. This activity involved the removal of 325 structures and coincided with the performance of portions of the SI and RI. During decommissioning and demolition activities, residual product and other Facility-related influences encountered within the structures were addressed in compliance with federal, state, and local regulations and in a manner that prohibited the materials from entering the environment (e.g. off-site disposal).

A review and screen of RI data conducted as part of the EE/ERA identified areas that require remediation to address historical Facility-related effects (e.g., disposal areas, source areas). Additional RI or risk assessment in these areas is unlikely to influence the decision to remediate these areas. Pre-design investigations are underway in these areas to support remedy selection and design. These “Areas of Presumed Remedial Action” are further discussed in Section 3.3.4.1.

3.2.3 Facility Redevelopment

The overarching objective of the SI/RI process (including the EE/ERA) is to generate information necessary to identify a remedy protective of human health and the environment while allowing development of the Facility as a source of ratable income for the local community. Future use at the Facility is considered in remedial action objectives and incorporated into the design, ultimately positioning the Facility for reuse. Anticipated future use at this Facility includes a mixture of preserved open space, and light industrial/ commercial development within the former manufacturing areas, with the potential for a commuter town center focused around the adjacent commuter railroad station (NJ Transit Mount Arlington Station). Heavy rail access and the Interstate 80 corridor make this property very desirable for redevelopment.

Hercules, Roxbury Township, the New Jersey Highlands Council, and the New Jersey Office of Smart Growth developed conceptual future use plans for the Facility. Following cessation of operations in 1996 and throughout the decommissioning and environmental investigation process, the future use plans focused redevelopment in the central core of the Facility, in areas corresponding to those previously developed for Facility operations. The wetland complex at the southern end of the Facility, as well as Duck Pond and the forested area to the north, remain undeveloped as natural open space. Similarly, the steep wooded ridgelines that bound the Facility remain primarily undeveloped. With these plans in mind, Hercules anticipates placing a conservation easement on the wooded ridgeline along the eastern boundary of the Facility in partial fulfillment of its natural resource damage claim currently being negotiated with the NJDEP (Attachment 2).

In the years following decommissioning and demolition activities, former operational areas of the Facility have remained vacant, vegetation grows, and community succession continues. During this same time period, the State of New Jersey promulgated the Highlands Act and the NJDEP developed a new means of mapping potential habitat for sensitive species (Landscape Project version 3.0 using species-based patch models) and indirectly influencing future land use. A variety of related initiatives have followed the Highlands Act, such as sewer service area planning and watershed management planning at the county and local levels.

Hercules continues to develop a remedial strategy for the Facility that positions portions of the former operational areas for redevelopment while preserving the Facility's natural resources. This approach aligns with the brownfields redevelopment concept, best management practices (e.g., low-impact development and stormwater

management), NJDEP land use practices, conceptual development plans prepared by Roxbury Township, and infrastructure already in place to support redevelopment (e.g., transit station, heavy rail access, water and wastewater resources). Aligning redevelopment with former operational areas of the Facility investigated in the RI facilitates coupling a presumptive cap/cover remedy with Facility redevelopment.

3.3 Ecological Conceptual Site Model

Facility development, operations, and operational incidents served as historical sources and distributive processes by which constituents entered environmental media (primarily soil) at the Facility. The import of historic fill materials in the early 1900s, as well as precipitation and stormwater runoff draining from adjacent areas to the Facility, provide additional historical and current constituent sources. Time and natural processes (e.g., erosion, sorption, degradation) influence the distribution of constituents within soil, as well as from soil to secondary and tertiary media (e.g., groundwater, surface water, sediment, and biological tissue). As Facility operations changed through time, these distributive processes changed and altered the conditions in which potential exposures could occur.

3.3.1 Potential Ecological Exposure Pathways

Potential ecological receptors onsite and in the surrounding environment can be directly or indirectly exposed to constituents in environmental media if a complete exposure pathway exists. An exposure pathway is considered complete if it contains the following five elements:

- Constituent source
- Release mechanism to the environment
- Transport medium
- Receptor contact at the exposure point
- Exposure route.

Important considerations when evaluating exposure pathway completeness include:

- Constituent concentrations in different media and their respective locations
- Physical and chemical properties of Facility-related constituents
- Locations of environmentally sensitive areas.

Potentially complete exposure pathways for each medium are discussed in the following sections. A graphical ecological CSM showing potential media, pathways, and ecological receptors is provided on Figure 3-1.

3.3.1.1 Surface Soil

Potential exposure routes associated with surface soil[3] include direct contact, ingestion, inhalation, and indirect exposure (i.e., food-web transfer). Constituents in soil possess varying degrees of potential for exposure through each of these exposure routes depending on chemical-specific parameters. The following potentially complete exposure pathways to surface soil were identified:

- Incidental contact with constituents in soil (i.e., dermal exposure) by plants and soil invertebrates is a complete exposure pathway. Plants and soil invertebrates are directly exposed to constituents from the soil. This pathway is quantitatively evaluated in the EE/ERA by comparing soil constituent concentrations to soil ecological screening benchmarks (ESBs) that are protective of plants and soil invertebrates.

- Ingestion of constituents in soil by plants and soil invertebrates is a complete exposure pathway. Plants and soil invertebrates may directly ingest constituents from the soil. This pathway is quantitatively evaluated in the EE/ERA by comparing soil constituent concentrations to soil ESBs.

- Indirect exposure to soil via food-web transfer of bioaccumulative constituents is a complete exposure pathway for upper-trophic level wildlife receptors (i.e., birds and mammals). Bioaccumulative constituents taken up by soil invertebrates and plants may be consumed by mammalian and avian wildlife as part of their diets. This pathway is quantitatively evaluated in the EE/ERA in a food-web model.

- Incidental ingestion of contaminated soil by upper-trophic level wildlife (i.e., birds and mammals) is a complete exposure pathway. Wildlife may indirectly ingest constituents from soil during foraging. This pathway is quantitatively evaluated in the EE/ERA in a food-web model.

[3] This EE/ERA evaluates a surface soil sample as a soil sample with a starting depth from 0 to 1 foot below ground surface (bgs) and an end depth no more than 3 feet bgs. This evaluation accounts for the size and variability of the SI/RI dataset and includes sample intervals spanning the biologically active zone (BAZ).

- Incidental contact with constituents in soil (i.e., dermal exposure) by wildlife is a potentially complete exposure pathway. Wildlife may have direct exposure to soil while burrowing and/or preening; however, because fur or feathers greatly reduce the potential exposure, direct contact with soil is considered a minor, *de minimis* pathway for wildlife and is not evaluated quantitatively (Suter 2007).

- Inhalation of constituents in soil by wildlife, via inhalation of airborne soil particulates or volatilization of constituents from the soil, is a potentially compete exposure pathway. However, inhalation as a route of exposure is likely to be insignificant compared to other routes of exposure for two reasons:

  – Vegetative cover would prevent substantial production of airborne particulates due to wind erosion.

  – Most constituents in soil are unlikely to volatilize from the soil due to their physicochemical properties. Those constituents that may volatilize are unlikely to be present in substantial concentrations following volatilization and subsequent dispersal.

  As a result, the inhalation pathway is considered insignificant (Suter 2007) and is not quantitatively evaluated.

3.3.1.2 Surface Water

Direct contact with surface water represents a potentially complete exposure pathway for both aquatic and terrestrial receptors. Aquatic receptors such as fish and water column invertebrates may be directly exposed to constituents in surface water via ingestion and direct contact/uptake. Exposure to surface water is evaluated by comparing surface water ESBs that are protective of aquatic life to surface water data.

Upper-trophic level aquatic and terrestrial wildlife receptors may ingest surface water; however, surface water ingestion represents a *de minimis* exposure pathway for constituents, when compared to wildlife exposure via ingestion of dietary food items, soil and/or sediment. As such, the surface water ingestion pathway for wildlife receptors is not quantitatively evaluated.

3.3.1.3 Surface Sediment

Surface sediment represents the primary medium for aquatic receptor exposure to constituents. Exposure to sediment occurs in the BAZ, which is identified based on levels of dissolved oxygen, bioturbation, and other biological processes (Interstate Technology & Regulatory Council [ITRC] 2011). Ecological receptors may be exposed to constituents in surface sediment via three potential routes of exposure: direct contact, ingestion, and food-web transfer. The potential completeness of each of these exposure pathways is evaluated below:

- Direct contact with constituents bound to sediment is a potentially complete exposure pathway for aquatic plants and benthic invertebrates. Constituents bound to sediment and those dissolved in the interstitial water (pore water) of the sediment can affect aquatic plants and invertebrates through dermal contact and absorption into tissues. This pathway is quantitatively evaluated in the EE/ERA by comparing sediment constituent concentrations to ESBs protective of plants and benthic invertebrates.

- Ingestion of constituents bound to sediment is a potentially complete exposure pathway for aquatic plants and benthic invertebrates. Constituents bound to ingested sediment and in pore water may partition into invertebrate tissues through the lining of the digestive tract and via root uptake into aquatic plants. This pathway is quantitatively evaluated in the EE/ERA by comparing sediment constituent concentrations to sediment ESBs protective of aquatic plants and benthic invertebrates.

- Food-web transfer of constituents bound to sediment is a complete exposure pathway for upper-trophic level wildlife consumers. Constituents can accumulate in tissues of lower-trophic level aquatic organisms (e.g., benthic organisms, fish, aquatic plants), which are then consumed by avian and mammalian receptors. This pathway is quantitatively evaluated in the EE/ERA through food web modeling.

- Ingestion of sediment containing COPECs is a complete exposure pathway for upper-trophic level wildlife (i.e., birds and mammals). Wildlife may indirectly ingest constituents from sediment during foraging. This pathway is quantitatively evaluated in the EE/ERA in a food-web model.

3.3.2 Potential Ecological Receptors

Ecological receptor groups potentially exposed to constituents in terrestrial areas of the Facility include:

- Terrestrial plants
- Soil-dwelling invertebrates
- Mammals with terrestrial-based diets
- Birds with terrestrial-based diets

Ecological receptors potentially exposed to constituents in aquatic areas of the Facility include:

- Benthic invertebrates
- Aquatic plants
- Water column invertebrates
- Fish
- Mammals with aquatic-based diets
- Birds with aquatic-based diets

Specific receptors are selected to represent the organisms that could be present most frequently or are likely to be sensitive to the effects of constituents in environmental media. Selection considerations include the following factors:

- Occurrence of potentially complete pathways for exposure of ecological receptors to constituents in environmental media

- Resident communities or species exposed to the highest concentrations of constituents in environmental media

- Species or functional groups considered to be essential to, or indicative of, the normal functioning of the affected habitat

- Species of special status or designation (e.g., threatened or endangered) by state or federal entities

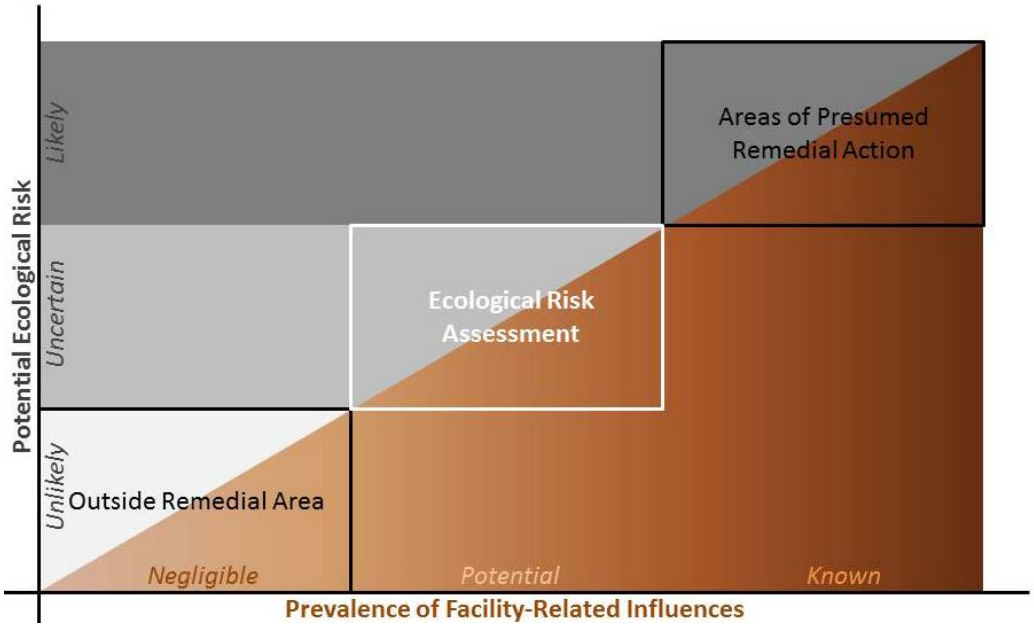
- Feasibility of completing a quantitative assessment for the identified pathways and receptors (e.g., availability of modeling parameters and toxicology values)

Based on the above criteria, the following ecological receptor populations and associated feeding guilds (where applicable) are evaluated in this EE/ERA:

- Terrestrial Area:
  - Terrestrial plant communities
  - Soil invertebrate communities
  - Insectivorous mammals (short-tailed shrew [*Blarina brevicauda*])
  - Insectivorous birds (American robin [*Turdus migratorius*])
  - Herbivorous birds (northern bobwhite [*Colinus virginianus*])
  - Herbivorous mammals (white-tailed deer [*Odocoileus virginianus*])
  - Carnivorous birds (red-tailed hawk [*Buteo jamaicensis*])
  - Carnivorous mammals (red fox [*Vulpes vulpes*])
- Aquatic Area:
  - Benthic invertebrate communities
  - Aquatic plant communities
  - Fish and aquatic invertebrate communities
  - Piscivorous mammals (mink [*Neovison vison*])
  - Piscivorous birds (great blue heron [*Ardea herodias*])
  - Herbivorous birds (mallard duck [*Anas platyrhynchos*])
  - Herbivorous mammals (muskrat [*Ondatra zibethicus*])
  - Insectivorous birds (tree swallow [*Tachycineta bicolor*])
  - Insectivorous mammals (little brown bat [*Myotis lucifugus*])

3.3.3 Exposure Areas

Results of SI/RI data collection as well as the habitat characterization, described in Section 3.2 supported the development of exposure areas. Exposure areas for the EE/ERA were selected based upon the Facility-specific EE/ERA approach, as described in Section 1, and as shown below.



By eliminating areas beyond the influences of historical Facility operations based on previous investigation results (e.g., areas beyond the Remedial Area), and areas where active remediation or removal will occur (Areas of Presumed Remedial Action), the exposure areas selected below represent portions of the Remedial Area of the Facility where the potential for ecological risk remains uncertain.

Terrestrial and aquatic exposure areas are discussed below and presented in Figures 3-2 and 3-3, respectively.

3.3.3.1 Terrestrial Exposure Area

The SI/RI identified a relative absence of Facility-related influences in undeveloped areas of the Facility and excluded these areas from further consideration in the RI. These areas flank the former operational areas of the Facility and provide contiguous corridors of mature forest habitat.

The formerly developed portion of the Facility (the Remedial Area) provides patches of habitat for ecological receptors. Upper-trophic-level ecological receptors using onsite terrestrial habitats are likely to move among the habitat patches that share a common list of Facility-related constituents, as well as similarities in habitat type and composition. As such, this EE/ERA evaluates potential exposure and risks to terrestrial

receptors using one Facility-wide terrestrial soil exposure area within the Remedial Area (Figure 3-2).

3.3.3.2 Aquatic Exposure Areas

Based on the distinct areas of surface water flow and the potential for groundwater to interact with surface water as identified during the RI, two aquatic exposure areas were identified for evaluation in this EE/ERA: Northern Drainage Area and Southern Drainage Area (Figure 3-3). These drainages support similar aquatic or semi-aquatic habitat, but different sources of hydrology influence these features, as discussed below:

- *Southern Drainage Area*. Surface water enters the Facility via a small stream channel along the northwestern Facility boundary, near the intersection of Howard Boulevard and Interstate 80. The stream flows southeast before entering a culvert beneath Powder Mill Road and discharges to the southern wetland complex. Overland flow and surface water runoff generally follow the same pattern, draining to aquatic features and flowing to the southern end of the Facility via a series of ditches and swales. These drainage features and the receiving waters of the southern wetland complex make up the Southern Drainage Area. The Southern Drainage Area captures the water bodies within the Remedial Area as well as the series of ditches that drain the southern wetland complex south of the Remedial Area boundary. These ditches receive surface water and suspended sediment from the southern wetland complex (within the Remedial Area boundary) that drains former operational areas of the Facility. These drainage channels also receive runoff from Howard Boulevard and Route 46. Ultimately the wetland complex drains to a single tributary that flows offsite at the southeastern corner of the Facility. Data from 2013 sampling at and proximate to this outlet indicate that Facility-related influences cease upstream of the outlet, thus the exposure area does not extend offsite.

- *Northern Drainage Area*. This drainage area consists of aquatic features located north and east of the small stream channel referenced above. Duck Pond serves as the primary drainage feature in the Northern Drainage Area, receiving water from surrounding stream channels, wetlands, and Shooting Pond. A series of isolated wetlands and pools also exist in the Northern Drainage Area. The Northern Drainage Area occurs almost entirely within the Remedial Area boundary; samples collected from an isolated pond that borders the Remedial Area were also included in the Northern Drainage Area.

3.3.3.3 Groundwater

Groundwater quality at the Facility is well defined. Given the long industrial history of the Facility, groundwater is largely unaffected by historic site operations (Hercules 2007, 2009, 2016), with the exception of a TNT plume in the southwestern corner of the Facility. TNT is observed in groundwater in proximity to the southern wetland complex, however, the influences of TNT in groundwater are not observed in surface-water and sediment in this area of the Facility.

Regional groundwater issues do have the potential to affect surface water and sediment quality at the Facility. For example, NJDEP, in cooperation with Hercules, evaluated a regional tetrachloroethene (TCE) groundwater plume adjacent to the Facility. They found that while the Facility falls within the footprint of the TCE plume, the Facility was not a contributor to the plume (Hercules 2007). However, the interaction between groundwater underlying the Facility and various surface water features (e.g., wetlands, ponds, ditches) represents a potential migration pathway for constituents unrelated to the Facility.

Ecological receptors are exposed to constituents in groundwater via groundwater discharges to surface-water features. As such, evaluating surface water and sediment characterizes potential ecological risk related to groundwater for aquatic receptors at the Facility.

3.3.4 Excluded Areas

As discussed, areas of the Facility where potential ecological risk is unlikely or likely are not evaluated in this EE/ERA. These excluded areas are summarized below.

3.3.4.1 Areas of Presumed Remedial Action

Based on a review of the CSM, historical Facility information, and SI/RI data, several process/disposal areas within the Remedial Area were identified as areas where remedial action is warranted, irrespective of the outcome of the EE/ERA. The locations, composition, and/or constituents present in these areas align with historical Facility practices and records from the Facility (e.g., disposal areas, explosions).

To guide the feasibility study process, these Areas of Presumed Remedial Action were prioritized using a tiered system. Tier ranking prioritizes remediation in areas of the Facility based (in part) on elements such as complexity of the remedy, severity of the

effects, duration of remedy implementation, and/or alignment with Facility redevelopment planning. The tiered organization includes the following areas:

- Tier I:
  - TNT Area (conglomerate of adjacent areas of concern)
- Tier II:
  - Ammonium Nitrate Area – Former Burning Ground and intervening areas of concern (H12-237, H13-1, H13-7)
  - B-Line Area – Disposal Area (M8-1)
  - Diazo Area – Diazo Ponds (H8-1)
  - B-Line Area - Dinitrotoluene (DNT) Heater House (L11-2091)
  - Development Area – Old Burning Ground and adjacent areas of concern to the southwest (M5-3, L5-2313, L5-10, L5-2275, L5-539)
- Tier III:
  - Storage Area – Disposal Area (N6-1)
  - B-Line Area – South (conglomerate of adjacent areas of concern)
  - A-Line Area – Northwest (conglomerate of adjacent areas of concern)

Acknowledging the pending remedial actions in the Tier I, II, and III areas, data from these areas are not included in this EE/ERA. Table 3-1 provides information regarding the history, constituent fate and transport, and presumptive remedy for each area. Figure 3-2 notes these areas on a site plan.

3.3.4.2 Areas Beyond the Remedial Area Boundary

The SI/RI identified the Remedial Area by comparing sample results from undeveloped areas around the margins of the Facility to criteria protective of human health (i.e., soil remediation goals). Once established, additional site characterization activities focused on the Remedial Area. This EE/ERA relies on the Remedial Area to focus assessment activities. As part of establishing the assessment area, sample results from undeveloped areas around the margins of the Facility (outside the Remedial Area) were evaluated in the context of potential ecological risk.

3.3.5 Summary

This EE/ERA uses data collected as part of site characterization activities. Where potential ecological risk is likely (i.e., in Areas of Presumed Remedial Action), Hercules is committed to active remediation and focusing efforts on remedial planning. Acknowledging undeveloped areas of the Facility beyond the influence of former operations (i.e., beyond the Remedial Area boundary) allows the evaluation to focus on the remaining areas of the Facility where potential ecological risk is uncertain.

3.4 Assessment and Measurement Endpoints

AEs provide explicit expressions of the actual environmental values (i.e., ecological resources) that are to be protected at the Facility (USEPA 1997) and are based on the complete exposure pathways and receptor categories identified in the CSM. Four principal criteria are used to select ecological values that may be appropriate for use as AEs (USEPA 1998):

1. Ecological relevance
2. Susceptibility to known or potential stressors
3. Commercial or social value
4. Relevance to management goals

AEs focus risk assessment to components that could be adversely affected by COPECs at a site. AEs are typically communities or trophic guilds (e.g., insectivorous birds). Trophic guilds may be deemed at risk if statistically significant, population-level effects occur to reproduction or survival of a receptor species representing the subject trophic guild.

Population-level effects of concern include:

- Mortality, growth, or reproductive effects resulting from direct exposure to constituents that may result in population-level effects.

- Mortality, growth, or reproductive effects resulting from exposure to constituents that have bioaccumulated in the food web and may result in effects to trophic-level receptor populations.

- Indirect effects associated with a substantial reduction in abundance of prey populations.

MEs are characteristics, quantifiable through laboratory or field experimentation, that are related to the valued characteristic chosen as the AE (USEPA 1992a, 1998). The ME represents the same exposure pathway and mechanisms of toxicity as the associated AE.

Based on the complete exposure pathways and potential receptor categories identified at the Facility, the following AEs and MEs were identified for each of the selected receptor groups (Table 3-2). The AEs are phrased as risk questions and the MEs were selected to address these questions, as presented below.

Terrestrial Area

AE 1. Could direct contact with COPECs in Facility soil affect the structure, function, and/or survival of the terrestrial plant community?

- ME 1. Compare concentrations of COPEC in soil to ESBs protective of terrestrial plants.

AE 2. Could direct contact with COPECs in Facility soil affect the structure, function, and/or survival of the terrestrial invertebrate community?

- ME 2. Compare concentrations of COPECs in soil to ESBs protective of terrestrial invertebrates.

AE 3. Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of herbivorous avian and mammal populations?

- ME 3. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for herbivorous birds and mammals (represented by northern bobwhite and white-tailed deer).

AE 4. Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of insectivorous avian and mammal populations?

- ME 4. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for insectivorous birds and mammals (represented by American robin and short-tailed shrew).

AE 5. Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of carnivorous avian and mammal populations?

- ME 5. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for carnivorous birds and mammals (represented by red-tailed hawk and red fox).

Aquatic Areas

AE 6. Could direct contact with COPECs in sediment in each area affect the structure, function, and/or survival of the benthic invertebrate community?

- ME 6. Compare COPEC concentrations in sediment in the Northern and Southern Drainage Areas to ESBs protective of benthic invertebrates.

AE 7. Could direct contact with COPECs in sediment in each area affect the survival and function of aquatic plant populations?

- ME 7. Compare COPEC concentrations in sediment in the Northern and Southern Drainage Areas to ESBs protective of terrestrial plants.

AE 8. Could direct contact with COPECs in surface water in each area affect the survival and reproduction of fish and aquatic invertebrate populations?

- ME 8. Compare COPEC concentrations in surface water in the Northern and Southern Drainage Areas to ESBs protective of fish and aquatic invertebrates.

AE 9. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of herbivorous avian and mammal populations?

- ME 9. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for herbivorous birds and mammals (represented by mallard duck and muskrat) in the Northern and Southern Drainage Areas.

AE 10. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of insectivorous avian and mammal populations?

- ME 10. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for insectivorous birds and mammals (represented by tree swallow and little brown bat) in the Northern and Southern Drainage Areas.

AE 11. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of piscivorous avian and mammalian populations?

- ME 11. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for piscivorous birds and mammals (represented by great blue heron and mink) in the Northern and Southern Drainage Areas.

4. Data Review and COPEC Selection

Information in the following sections describes the data available from previous investigations described in Section 3.2 and data consolidation procedures used in the EE/ERA. The data were then screened against literature-based benchmarks to identify COPECs for quantitative evaluation in the EE/ERA.

4.1 Data Usability

The SI/RI dataset was reviewed for applicability to the EE/ERA. Data collected as part of the SI and Phase I RI were validated by a third-party validator in accordance with USEPA's Region II Standard Operating Procedures (SOPs) for data validation. The quality of the data was assessed according to USEPA's PARCC (precision, accuracy, representativeness, comparability and completeness) parameters. These criteria were used to identify unacceptable or biased data that could result in corrective actions being implemented, or otherwise require qualification of the data. Reporting limits provided by the laboratory were elevated if the sample was analyzed at a dilution; however, data were not qualified based on elevated reporting limits. The evaluation of the data against PARCC criteria provided information on the data quality and reliability. Phase II RI data were validated in accordance with NJDEP guidance on data usability. As a result of these evaluations, data are considered to be of known and acceptable quality, and are considered valid and usable for decision-making purposes (Hercules 2007). Available site characterization data used in the EE/ERA are described below.

4.1.1 Ecological Risk Assessment Dataset Selection

Data selected for the EE/ERA include surface soil and sediment samples from the 0- to 12-inch interval below soil/sediment surface (bss; representative of the BAZ) and surface water sample results. Where historical information contained in the database was ambiguous (e.g., sample interval recorded as 12 inches without listing both a start and ending depth bss), samples that included any portion of the 0- to 12-inch bss

interval, including those listed as being collected from 12 inches bss, were included in the EE/ERA dataset. A soil sample with a starting depth of 0- to 1- foot bss and an end depth no more than 3 feet bss was also included. This definition accounts for the size and variability of the SI/RI dataset and includes sample intervals spanning the BAZ. Table 4-1 summarizes samples available for the EE/ERA dataset. Consistent with the approach outlined in Section 1.2, the dataset was separated into the following exposure areas:

- Within the Remedial Area, outside Areas of Presumed Remedial Action
- Within Areas of Presumed Remedial Action
- Outside the Remedial Area

As previously discussed, this EE/ERA focuses on data from sample locations within the Remedial Area, and excludes data from the Areas of Presumed Remedial Action (hereafter referred to as the ERA dataset [Appendix A]). Appendix B presents data for each Area of Presumed Remedial Action. Appendix C presents data from the undeveloped areas beyond the Remedial Area boundary.

The EE/ERA dataset was also separated by medium: soil (2000+ samples), sediment (500+ samples), and surface water (300+ samples). Figures 4-1 through 4-15 illustrate the spatial coverage of sample locations by constituent class. As discussed in Section 3.3.3, the soil dataset was evaluated as a whole based on the similarity in constituent composition and habitat suitability across former manufacturing areas of the Facility, while the sediment and surface water datasets were divided into two exposure areas (Northern and Southern Drainage Areas). The figures demonstrate the spatial coverage of samples included in the EE/ERA for terrestrial and aquatic exposure areas. The Phase II RIR (Hercules 2016) presents sample locations, sample IDs, and results on a sample-by-sample basis. RI conclusions indicate that constituents occur primarily within the former operational areas and acknowledge that the horizontal extent of constituents is well defined.

4.1.2 Data Management

Specific data handling was required to achieve spatial representativeness for the EE/ERA. Duplicate analyses at one sample location (e.g., field duplicates), or constituents analyzed by more than one method, create spatial disparity among the dataset during statistical evaluation. Additional data reduction and handling was

conducted to minimize these influences. The following subsections present methods and rationale for additional database management to facilitate the COPEC screen.

4.1.2.1 PCDDs and PCDFs

The PCDD/F soil sample dataset is relatively small (n=20) compared to the Facility-wide soil characterization dataset. The spatial coverage of the datasets differ considerably, as sampling for polychlorinated dibenzo-*p*-dioxins (PCDDs) and polychlorinated dibenzo-*p*-furans (PCDFs) focused on four former burning grounds at the Facility at the request of NJDEP. Given these differences, PCDD/F is evaluated separately (Appendix D). Results of the evaluation are discussed in sections of this EE/ERA where applicable. The soil volume of the Phase II RIR (Hercules 2016) provides additional information regarding the genesis of PCDD/F soil sampling at the Facility.

4.1.2.2 Duplicate Samples

Field duplicate samples are presented in tables in brackets next to their parent sample (i.e., XX [YY]). One numerical representation of parent/duplicate data was derived for use in risk calculations to avoid spatial weighting bias associated with two results at the same sample location. When the parent/duplicate data were either both detects or both non-detects, sample results were averaged. Because field duplicates are co-located, sample variation caused by potential heterogeneity is also included in the measurement (USEPA 1991). The average concentration provides for the best representation of concentration at that location. In situations where one-half of a parent/duplicate pair was detected and the other half was not detected, the detected concentration was used, which provides for a conservative measurement.

4.1.2.3 Redundant Analytes – SW846 Methods 8270 and 8330

Eight constituents occur on the analyte lists for both the SW846 8270 semivolatile organic compound (SVOC) and SW846 8330 E&E methods. As such, the SI/RI database contains two results for each constituent at each sample location where both methods were used.

For this EE/ERA, NJDEP's acceptance of data based on laboratory certification (which is based on the analytical methods meeting precision and accuracy targets) was used. Method SW846 8270 is a gas chromatography/mass spectrometry (GC/MS) method and SW846 8330 uses high-performance liquid chromatography (HPLC); each method

offers distinct advantages and disadvantages depending on the target analyte. The table below summarizes the eight analytes and associated NJDEP-approved analytical methods, and notes the data selected for use in this EE/ERA.

Analyte	NJDEP Laboratory Certification[1]		Data used in EE/ERA
	SW846 8270	SW846 8330	
2,4-DNT	X	X	SW846 8270
2,6-DNT	X	X	SW846 8270
2-nitrotoluene		X	SW846 8330
3-nitrotoluene		X	SW846 8330
4-nitrotoluene		X	SW846 8330
Nitrobenzene	X	X	SW846 8330
1,3,5-trinitrobenzene	X	X	SW846 8330
2,4-dinitrophenol	X		SW846 8270

Note:

[1]Application for Certification of Environmental Measurements, Part III – Analytical Testing Parameters (NJDEP 2014).

For analytes with one NJDEP-approved laboratory analytical method, data from the approved method was selected for use in the EE/ERA. Where the NJDEP approves both analytical methods, additional information related to precision and accuracy of the methods as they relate to analytes (or analyte families) was evaluated. For nitrotoluene compounds, the GC/MS method (8270) generates chromatographs enabling the analytical laboratory to more precisely identify individual compound peaks and accurately quantify associated concentrations. Conversely, the HPLC (8330) methods provide superior performance for the analysis of nitrobenzene compounds. This rationale is consistent with that provided in the Phase I RIR (Hercules 2007).

4.1.2.4 Redundant Analytes – SW846 Methods 8260 and 8270

Six constituents occur on the analyte lists for both the SW846 8270 SVOC and SW846 8260 volatile organic compound (VOC) methods. As such, the SI/RI database contains two results for each constituent at each sample location where both methods were used.

The NJDEP approves both analytical methods for six constituents (1,2,4-trichlorobenzene, 1,2-dichlorobenzene, 1,3-dichlorobenzene, 1,4-dichlorobenzene, hexachloro-1,3-butadiene, and naphthalene). With the exception of naphthalene, these

constituents were not retained as COPECs during the initial data screen (see Section 4.2.2).

Naphthalene was retained as a COPEC based on maximum detected concentrations for both the VOC and SVOC data. The SVOC analysis of naphthalene featured a larger number of data points and a higher 95% upper confidence limit (95UCL) compared to the dataset for naphthalene as a VOC. Naphthalene also represents one of the 17 constituents that make up the PAH subset of SVOCs. As such, this EE/ERA evaluates naphthalene as an SVOC.

4.2 Identification of Constituents of Potential Ecological Concern

COPECs are identified via a comparison of generic ESBs to maximum detected constituent concentrations in environmental media. Generic ESBs represent a threshold concentration that a majority of target organisms (e.g., plants, invertebrates) can tolerate and a concentration that may cause adverse effects in specific organism communities. Generally, ESBs were developed from various datasets that relate constituent concentrations in an environmental medium with occurrence of effects in sensitive species. Generic ESBs do not consider site-specific factors that may affect constituent bioavailability and toxicity (e.g., pH, organic carbon content). Ecological screening benchmarks utilized in this EE/ERA are summarized below.

4.2.1 Ecological Screening Benchmarks

Ecological screening benchmarks were selected from NJDEP's Ecological Screening Criteria (ESC) table (NJDEP 2009) and supplemented with ESBs from the following additional sources:

- Resource Conservation and Recovery Act (RCRA) Region 5 Ecological Screening Levels (ESLs; USEPA 2003a)
- Ecological Soil Screening Levels (EcoSSLs) (USEPA 2007a)
- Ecotoxicology of Explosives (Sunahara et al. 2009)
- Nitroaromatic Munition Compounds: Environmental Effects and Screening Values (Talmage et al. 1999)

- Region 3 Biological Technical Assistance Group - Freshwater Sediment and Freshwater Screening Benchmarks (USEPA 2006)

- Munition constituents: Preliminary sediment screening criteria for the protection of marine benthic invertebrates (Pascoe et al. 2010)

- Ecotoxicological Serious Risk Concentrations for soil, sediment, and (ground)water (Verbruggen et al. 2001)

- USEPA's Ecotox Database (available at http://cfpub.epa.gov/ecotox/)

- Acute Oral Toxicity and Repellency of 933 Chemicals to House and Deer Mice (Schafer et al. 1985)

- Comparison of Lethality, Reproduction, and Behavior as Toxicological Endpoints in the Nematode *Caenorhabditis elegans* (Dhawan et al. 1999)

- Toxicity of Trihalomethanes to Common Carp Embryos (Mattice et al. 1981).

Table 4-2 summarizes ESBs used in this EE/ERA. For constituents lacking ESB, surrogate values from constituents with similar properties (e.g., chemical class, molecular structure) were selected. Surrogate values and their sources are footnoted in Table 4-2.

Surface water ESBs for certain metals (i.e., cadmium, chromium, copper, nickel, silver, and zinc) presented in the NJDEP ESC table are hardness-dependent. Representative hardness values were calculated for both the Northern and Southern Drainage Areas using available surface water data. An average hardness value and a 95UCL were calculated for each area. The table below summarizes hardness values, presented as milligrams per liter (mg/L) calcium carbonate.

Representative Hardness Values (mg/L)		
	Northern Drainage Area	**Southern Drainage Area**
Average	57	120
95UCL	84	155

In both the Northern and Southern Drainage Areas, the average hardness value was lower than the 95UCL value. As such, the calculated screening values were lower using the average hardness, which represents the more conservative approach for screening surface water data. Screening values were calculated for both total and dissolved metals per the NJDEP ESC table (2009) equations using a conversion factor. Table 4-2 presents hardness-dependent ESB.

Where appropriate, organic carbon-normalized sediment ESBs were calculated using drainage area-specific total organic carbon (TOC) data. Average drainage area-specific TOC content in sediment is 6 percent in the Northern Drainage Area and 13 percent in the Southern Drainage Area. Table 4-2 presents drainage area-specific TOC-normalized sediment ESBs.

4.2.2 COPEC Screen

The maximum concentration of each detected constituent was compared to its ESB to calculate a hazard quotient (HQ). Constituents with HQs greater than 1 or those lacking an ESB were retained as COPECs. Constituents were not retained as COPECs if they were not detected (i.e., 0 detections), had a low frequency of detection (i.e., less than 5 detections irrespective of the number of samples analyzed), or if the HQ was less than 1. Tables 4-3 through 4-7 present the COPEC screen and associated summary statistics by sample media and exposure area.

The following sections summarize selected COPECs by media, exposure area, and constituent class. Table 4-8 summarizes COPECs identified onsite.

4.2.2.1 Facility-Wide Soil

A total of 42 COPECs were identified in Facility-wide soil (Tables 4-3 and 4-8). The following table summarizes COPECs by constituent class.

COPEC Summary – Facility-Wide Soil				
VOCs	**SVOCs**	**Metals**	**E&E**	**PCBs**
Benzene	2,4-DNT	Antimony	1,3,5-Trinitrobenzene	Aroclor 1254
Bromomethane	2,6-DNT	Arsenic	TNT	Aroclor 1260
---	Benzo(a)anthracene	Cadmium	2-Amino-4,6-DNT	Total PCBs
---	Benzo(a)pyrene	Chromium	4-Amino-2,6-DNT	---
---	Benzo(g,h,i)fluoranthene	Cobalt	HMX	---
---	Benzyl butyl phthalate	Copper	Nitrocellulose	---
---	Bis(2-ethylhexyl)phthalate	Lead	Nitroglycerin	---
---	Chrysene	Manganese	PETN	---
---	Di-n-butyl phthalate	Mercury	RDX	---
---	Naphthalene	Nickel	---	---
---	N-nitrosodi-n-propylamine	Selenium	---	---
---	N-nitrosodiphenylamine	Silver	---	---
---	Phenanthrene	Thallium	---	---
---	---	Vanadium	---	---
---	---	Zinc		---

Notes:
RDX = Royal Demolition Explosive (hexahydro-1,3,5-trinitro-1,3,5-triazine)
HMX = High Melting Explosive (octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine)

Metals commonly considered essential nutrients (i.e., calcium, iron, magnesium, potassium, and sodium) were not retained as COPECs. The soluble fraction of aluminum in soil can pose a potential risk to ecological receptors; however, it is understood that solubility, and therefore bioavailability, is based on the measured pH of onsite soil. Potential ecological risks associated with aluminum are only expected to occur when soil pH is less than 5.5 (USEPA 2003b). The 95UCL for soil pH was calculated from both field (pH = 5.8) and laboratory samples (pH = 6.1). As such, aluminum was not retained as a COPEC.

4.2.2.2 Northern Drainage Area

The Northern Drainage Area encompasses aquatic areas located north and east of the surface water divide described in Section 3.3.3.2). Aquatic features include Duck Pond, Shooting Pond, and associated tributaries, as well as smaller isolated ponds (miscellaneous ponds). Figure 3-3 shows the Northern Drainage Area.

4.2.2.2.1 Northern Drainage Area Surface Water

Four COPECs were identified in Northern Drainage Area surface water (Table 4-4) and below.

COPEC Summary – Northern Drainage Area Surface Water
Metals
Copper
Lead
Nickel
Zinc

Metals were retained as COPECs based on a conservative comparison of total metals data to ESBs. COPEC screening using dissolved metals data, which better approximates the fraction of the metal that is available for uptake by aquatic organisms (i.e., bioavailable, not bound to suspended particulates) (International Council on Mining and Metals [ICMM] 2007; Meyer et al. 2007; USEPA 1993a), would retain only copper, lead, and zinc as COPECs with HQs reduced by at least one order of magnitude (Table 4-4).

Table 4-4 presents the results of the COPEC screen and provides summary statistics for COPECs identified in surface water in the Northern Drainage Area.

4.2.2.2.2 Northern Drainage Area Sediment

Twenty-one COPECs were identified in Northern Drainage Area sediment (Table 4-5). The following table summarizes Northern Drainage Area sediment COPECs by constituent class.

COPEC Summary – Northern Drainage Area Sediment		
SVOCs	**Metals**	**E&E**
Benzo(a)anthracene	Arsenic	Nitrocellulose
Benzo(a)pyrene	Beryllium	Nitroglycerin
Benzo(g,h,i)perylene	Cadmium	---
Benzo(k)fluoranthene	Chromium	---
Chrysene	Copper	---
Dibenzo(a,h)anthracene	Lead	---
Fluoranthene	Mercury	---
Phenanthrene	Nickel	---
Pyrene	Silver	---
---	Zinc	---

4.2.2.3 Southern Drainage Area

The Southern Drainage Area encompasses aquatic areas south and west of the surface water divide described in Section 3.3.3.2. Aquatic features include intermittent

and perennial ditches draining to, and including, the southern wetland complex. Figure 3-3 shows the Southern Drainage Area.

4.2.2.3.1 Southern Drainage Area Surface Water

Eleven COPECs were identified in Southern Drainage Area surface water (Table 4-6). The following table summarizes COPECs by constituent class.

COPEC Summary – Southern Drainage Area Surface Water	
SVOCs	**Metals**
Chrysene	Aluminum
---	Arsenic
---	Cadmium
---	Copper
---	Lead
---	Manganese
---	Mercury
---	Selenium
---	Silver
---	Zinc

Metals were retained as COPECs based on a conservative comparison of total metals data to ESBs. COPEC screening using dissolved metals data, which better approximates the fraction of the metal that is available for uptake by aquatic organisms (i.e., bioavailable, not bound to suspended particulates) (ICMM 2007, Meyer et al. 2007; USEPA 1993a), would retain no metals as COPECs. Chrysene, a constituent insoluble in water, detected in surface water is likely attributable to chrysene bound to sediment or organic matter suspended in the sample matrix.

4.2.2.3.2 Southern Drainage Area Sediment

Thirty-six COPECs were identified in Southern Drainage Area sediment (Table 4-7). The following table summarizes Southern Drainage Area sediment COPECs by constituent class.

COPEC Summary – Southern Drainage Area Sediment			
VOCs	**SVOCs**	**Metals**	**E&E**
Tetrachloroethene	2,4-DNT	Antimony	2,4,6-TNT
---	Acenaphthene	Arsenic	Nitrobenzene
---	Acenaphthylene	Beryllium	Nitrocellulose
---	Anthracene	Cadmium	---
---	Benzo(a)anthracene	Chromium	---
---	Benzo(a)pyrene	Copper	---
---	Benzo(g,h,i)perylene	Lead	---
---	Benzo(k)fluoranthene	Manganese	---
---	Bis(2-Ethylhexyl)phthalate	Mercury	---
---	Chrysene	Nickel	---
---	Dibenzo(a,h)anthracene	Selenium	---
---	Fluoranthene	Silver	---
---	Fluorene	Thallium	---
---	Indeno(1,2,3-cd)pyrene	Zinc	---
	N-nitrosodiphenylamine	---	
---	Naphthalene	---	---
---	Phenanthrene	---	---
---	Pyrene	---	---

5. Ecological Exposure Assessment

The exposure assessment estimates a dose for each COPEC to which a receptor could be exposed. Exposure to plants and soil invertebrates (i.e., earthworms) is estimated solely by the Facility-specific soil concentration. Exposure to fish is estimated by the Facility-specific surface water concentration. Exposure to benthic invertebrates is estimated by the Facility-specific sediment concentration. Exposure to upper-trophic-level wildlife (birds and mammals) is estimated using an average daily dietary dose calculated via a food web model that incorporates estimated concentrations of COPEC in the diet (Section 5.2).

5.1 Exposure Point Concentrations

The exposure point concentration (EPC) is a conservative estimate of the average chemical concentration in an environmental medium. An individual receptor is assumed to be equally exposed to media within all portions of the exposure unit over the time frame of the risk assessment (USEPA 2002). USEPA recommends using the average concentration to represent "a reasonable estimate of the concentration likely to be contacted over time" (USEPA 1989). In addition USEPA (1992b) notes that “because of the uncertainty associated with estimating the true average concentration at a site, the 95 percent upper confidence limit (95UCL) of the arithmetic mean should be used for this variable.” In cases where the maximum detected concentration exceeds the 95UCL, the maximum detected concentration becomes the EPC. EPCs were calculated for COPECs identified at the Facility in soil, sediment and surface water, as indicated in Table 4-8.

To evaluate potential effects to lower-trophic-level organisms (i.e., soil invertebrates, plants, and benthic invertebrates), both the maximum detected concentration and the 95UCL are used as EPCs. Using both values for the EPC ensures that potential ecological threats are not overlooked and considers the concentration of a COPEC to which receptors are likely to be exposed. To evaluate potential effects to wildlife, the 95UCL is used as the EPC because upper-trophic level organisms (i.e., birds and mammals) are mobile and are expected to move throughout an exposure area, rather than remaining sessile and limiting exposure to one location with a maximum concentration.

Although PCB Aroclors 1254 and 1260 were selected as COPECs during the initial data screen, only the concentration of total PCBs (sum of detected Aroclors) was carried forward for use in food web modeling. This value provides a more

conservative estimate of the concentration of PCBs in Facility media. Aroclors are mixtures of individual PCB congeners, and the value for total PCBs incorporates the congeners that make up Aroclors 1254 and 1260.

5.1.1 Site Media

95UCLs were calculated for soil, surface water, and sediment using ProUCL Version 4.1.00. Per USEPA (2010) guidance, 95UCL calculation requires a dataset with at least eight samples and five detects. For datasets that do not meet this requirement, the maximum concentration was used as the EPC. Due to the size of the datasets and number of samples collected for each COPEC, non-detects in the database were excluded from 95UCL calculations. Due to the large number of samples available for each media from across the Facility, excluding these data does not have a meaningful impact on the spatial representativeness of the dataset. Tables 5-1 through 5-5 present EPCs and their basis for terrestrial and aquatic exposure areas. Appendix E presents ProUCL output files.

5.1.2 Estimated Tissue Concentrations

In the absence of Facility-specific tissue concentrations, soil bioaccumulation factors (BAFs) and biota-sediment accumulation factors (BSAFs) were used to estimate COPEC concentrations in biological tissue. These factors relate the concentration in environmental medium to which receptors are exposed to a tissue concentration. The bioavailability of each COPEC varies relative to physical and biological Facility-specific conditions; therefore, the use of BSAFs and BAFs introduces considerable uncertainty. BAFs and BSAFs are discussed below and in Section 8. Bioaccumulative compounds were selected from USEPA (2000).

5.1.2.1 Bioaccumulation Factors

BAFs are available for several COPECs to estimate concentrations in terrestrial organisms (i.e., soil invertebrates [earthworms], terrestrial plants, and mammals). Although bioaccumulation can vary substantially by species and site, these factors provide some bounding estimates of potential bioaccumulation to help assess potential risk and the need for additional Facility-specific bioaccumulation information.

BAFs may either be a simple factor by which the soil EPC is multiplied or based on a linear equation that incorporates the soil EPC.

Sources of BAFs include:

- Screening-Level Ecological Risk Assessment Protocol for Hazardous Waste Combustion Facilities – Appendices C through E (USEPA 1999)
- Guidance for Developing Ecological Soil Screening Levels (Eco-SSLs), including Attachment 4-1 – Exposure Factors and Bioaccumulation Models for Derivation of Wildlife Eco-SSLs (USEPA 2007a)
- Development and Validation of Bioaccumulation Models for Earthworms (Sample et al. 1998a)
- Development and Validation of Bioaccumulation Models for Small Mammals (Sample et al. 1998b)
- Empirical Models for the Uptake of Inorganic Chemicals from Soil by Plants (Bechtel Jacobs 1998)
- Literature-derived Bioaccumulation Models for Energetic Compounds in Plants and Soil Invertebrates (CH2M HILL 2005)
- Ecotoxicology of Explosives (Sunahara et al. 2009).

When multiple BAFs are available, BAFs based on a wide range of studies or a large dataset were preferentially selected over those developed based on more limited information. Terrestrial BAFs are presented in Table 5-6; the resulting estimated tissue concentrations are presented in Table 5-7.

5.1.2.2 Biota-Sediment Accumulation Factors

BSAFs were available for several COPECs to estimate tissue concentrations in aquatic organisms (i.e., fish and benthic invertebrates). While these values vary by species and site, they provide some bounding estimates of potential bioaccumulation to help assess potential risk and the need for additional Facility-specific bioaccumulation information.

Aquatic tissue concentrations estimated with BSAFs incorporate the organic carbon of the sediment and the percent lipid of the organism, according to the following equation:

$$C_{tissue} = \left(\frac{BSAF \times C_{sed} \times f_{lipid}}{f_{oc}}\right)$$

Where:

C_{tissue} = COPEC concentration in tissue (invertebrate or fish) (milligrams per kilogram [mg/kg])

BSAF = Biota-sediment accumulation factor (kilogram organic carbon per kilogram lipid [kg_{oc}/kg_l])

C_{sed} = COPEC concentration in sediment (mg/kg)

f_{lipid} = Fraction of lipid in tissue (kg_{oc}/kg_l)

f_{oc} = Fraction of organic carbon in sediment (kg_{oc}/kg_l)

Sources of BSAFs include:

- USEPA's Mid-Atlantic Ecology Division BSAF database (http://www.epa.gov/med/Prods_Pubs/bsaf.htm) (USEPA 2009)
- U.S. Army Corps of Engineers (USACE) BSAF database (http://el.erdc.usace.army.mil/bsafnew/) (USACE ERDC EL 2011[4])
- Empirical Models for the Uptake of Inorganic Chemicals from Soil by Plants (Bechtel Jacobs 1998)
- Literature-derived Bioaccumulation Models for Energetic Compounds in Plants and Soil Invertebrates (CH2M HILL 2005)
- Screening-Level Ecological Risk Assessment Protocol for Hazardous Waste Combustion Facilities – Appendices C through E (USEPA 1999).

Average lipid content was assumed to be 5 percent for fish and 3 percent for invertebrates, based on average lipid values from the USACE's BSAF database (USACE ERDC EL 2011). Consistent with the Phase I and Phase II RIRs (Hercules 2007, 2016), average sediment TOC concentrations were calculated for each drainage area using data specific to the drainage area. While the Phase I and Phase II RIRs

[4] This website is down for construction indefinitely.

(Hercules 2007, 2016) evaluated sediment using three areas (RI Areas I, II, and III), this EE/ERA evaluates sediment using the Northern and Southern Drainage Areas. Average TOC content for the Northern and Southern Drainage Areas of 13 and 6 percent, respectively, were used to calculate tissue concentrations.

BSAFs required for fish tissue concentration estimates were unavailable for several COPECs. As a result, BSAFs for invertebrates are used in lieu of BSAFs for fish tissue. Furthermore, BSAFs do not exist for aquatic plants; therefore, terrestrial BAFs were used. In other cases where BSAFs were unavailable, the BAF for soil invertebrates was selected as a conservative factor to estimate aquatic invertebrate and fish tissue concentrations.

The aquatic BSAFs are provided in Table 5-8; resulting tissue concentrations are provided in Table 5-9.

5.2 Upper-Trophic Level Wildlife Exposure

To evaluate potential exposure of a COPEC to upper-trophic-level wildlife (e.g., mammals and birds), a food web model is used to estimate the daily dietary dose to each receptor. This equation estimates the dose of a COPEC through dietary ingestion of soil/sediment and prey tissue items.

Generally, only bioaccumulative COPECs are modeled to upper-trophic-level wildlife, as these constituents accumulate in prey tissue and can be transferred up the food web via ingestion. As a result, chronic effects to survival, growth, and reproduction are the general endpoints of an ERA and are evaluated through the dietary ingestion pathway. Although upper-trophic level wildlife may also be exposed to non-bioaccumulative constituents via other pathways (e.g., inhalation, dermal exposure), these exposure pathways are generally considered *de minimis* and are not quantitatively evaluated in ecological risk assessments (Suter 2007).

For this EE/ERA, E&E constituents (although not considered bioaccumulative) were also run through food web models due to their direct ties to the Facility operational history and sitewide presence.

The food web model to estimate potential exposure to wildlife is as follows:

$$DDD = \frac{\{[(IR_f \times C_f) + (IR_s \times C_s)] \times SUF\}}{BW}$$

Where:

DDD	=	Daily dietary dose of COPEC (mg/kg per day)
C_f	=	Concentration of a COPEC in food (mg/kg)
IR_f	=	Daily ingestion of food (kilograms per day [kg/day])
C_s	=	Concentration of a COPEC in soil/sediment (mg/kg)
IR_s	=	Daily incidental ingestion rate of soil/sediment (kg/day)
SUF	=	Site use factor (unitless)
BW	=	Body weight (kilograms)

5.3 Exposure Parameters

Exposure parameters for upper-trophic-level wildlife receptors include dietary and incidental media (e.g., soil and/or sediment) ingestion rates, body weights, and dietary composition. These values were obtained from a variety of sources, including the USEPA's Exposure Factors Handbook (USEPA 1993b), Sample and Suter (1994), Nagy (2001), USEPA (2007), and Beyer et al. (1994). Exposure parameters were selected from a hierarchy of sources to preferentially select values based on measured data (e.g., Nagy 2001) instead of modeled data, and more recent sources instead of historical information. Table 5-10 presents the selected exposure parameters for the terrestrial and aquatic receptor species.

5.3.1 Dietary Ingestion Rates

Ingestion rates are generally presented on either a dry or fresh (wet) weight basis. Nagy (2001) presents actual dietary ingestion data for both wet and dry weight dietary tissue. Available values from Nagy (2001) were selected instead of values from other sources presenting only wet or dry weights that require conversion factors to obtain the corresponding wet or dry weight value. When values were not available in Nagy (2001), wet weight ingestion rates were selected from USEPA (1993b) and converted to dry weight ingestion rates using the following equation:

$$IR_{dw} = IR_{ww} \times (1 - Percent\ moisture)$$

Where:

IR_{dw}	=	Ingestion rate (dry weight)
IR_{ww}	=	Ingestion rate (wet weight)

Percent moisture	=	Invertebrates: 84 percent, tissue: 68 percent; plants: 85 percent (USEPA 2007a)

5.3.2 Soil/Sediment Ingestion Rates

Soil/sediment ingestion rates were preferentially selected from Beyer et al. (1994) for muskrat, American robin, northern bobwhite, red fox, and white-tailed deer. Soil ingestion rates for red-tailed hawk and short-tailed shrew are from USEPA (2007). If literature values less than 2 percent soil ingestion (by weight) were noted, or if no soil/sediment ingestion rate could be found for a particular species, a conservative value of 2 percent was used. The percent of soil/sediment ingested was multiplied by the dry weight ingestion rate to obtain the rate in kg/day.

5.3.3 Body Weights

Body weights were selected from Nagy (2001) when available. If unavailable, body weights were calculated as the mean adult and juvenile body weights provided in USEPA (1993b). Incorporating juvenile body weights is a conservative approach because it is protective of the juvenile portion of the population in addition to the adults.

5.3.4 Additional Exposure Assumptions

Several exposure parameters were assigned values based on conservative assumptions and best professional judgment per USEPA (1997) guidance. For example, the site use factor (SUF) is an input parameter representing the fraction of time that a wildlife receptor spends on site (based on factors such as proportion of a receptor's foraging range that is encompassed by the site or migratory patterns). This value was conservatively set to 1, implying that receptors spend 100 percent of their time in the exposure area.

Similarly, prey items with a potential to bioaccumulate COPECs were selected to represent the entirety of a receptor's diet. For instance, American robins do not solely ingest earthworms; however, their diet was conservatively assumed to consist only of earthworms (i.e., 100 percent). Use of these conservative assumptions is consistent with NJDEP (2015) and USEPA (1997) guidance and likely overestimates potential risk.

Table 5-10 summarizes the exposure parameters used to calculate the daily dietary dose for each receptor species.

6. Ecological Effects Assessment

The ecological effects assessment describes the potential effects associated with the exposure of identified COPECs to ecological receptors, and reflects the type of AEs selected. The potential for effects is estimated by comparing COPEC concentrations in receptor species (daily dietary doses) known effects concentrations from the literature. These benchmark values are concentrations of COPECs that are not expected to cause adverse effects to ecological receptors. ESBs were selected for evaluation of direct contact to lower-trophic-level organisms (i.e., invertebrates, fish, and plants) and wildlife toxicity reference values (TRVs) were selected to evaluate exposure to upper-trophic-level organisms (i.e., birds and mammals).

6.1 Toxicological Properties of COPECs

Brief toxicological profiles for major categories of COPECs (PAHs, metals, PCBs, E&E) are presented below.

6.1.1 Polycyclic Aromatic Hydrocarbons

PAHs are composed of two or more aromatic or benzene rings. There is a large number (>10,000) of possible PAH structures that occur in the environment as complex mixtures (USEPA 2003c). The ecological impact of PAHs is uncertain (Eisler 1987a). PAHs show little tendency for bioconcentration despite their high lipid solubility (Pucknat 1981), likely because most PAHs are rapidly metabolized. PAHs evaluated at the Facility include the common 16 priority pollutant PAHs identified by USEPA.

6.1.1.1 Invertebrates

PAHs deposited in sediments can affect benthic invertebrates differently, depending on the individual PAH and species of organisms. For instance, in sediment toxicity tests with the tubificid, *Limnodrilus hoffmeisteri*, Lotufo and Fleeger (1996) observed a median lethal phenanthrene concentration of 298 mg/kg. In the same study, pyrene concentrations up to 841 mg/kg were not acutely toxic. Decreases in tubificid reproduction were observed at lower levels. Bivalve molluscs tend to accumulate high PAH levels due to their inability to metabolize and excrete them (Eisler 1987a).

6.1.1.2 Fish

Most PAHs in aquatic environments are associated with particulate materials; only about 33% are present in dissolved form (Eisler 1987a). Fish have been shown to be capable of metabolizing PAHs better than other aquatic organisms (e.g., invertebrates) (Meador et al. 1995). Varanasi et al. (1985) as cited by the Agency for Toxic Substances and Disease Registry (ATSDR [1995]) ranked the extent of benzo(a)pyrene (BaP) metabolism by aquatic organisms as follows: fish > shrimp > amphipod > crustaceans > mussels. In addition, some fish species have been shown to avoid areas with high PAH concentrations (Rice 1973 in Pastorok et al. 1994).

6.1.1.3 Wildlife

In general, PAHs show little tendency to biomagnify in food webs, despite their high lipid solubility, likely because most PAHs are rapidly metabolized. PAH exposure to mammalian and avian laboratory species is reported for both low- and high-molecular-weight PAHs (USEPA 2007b). Juvenile mice orally ingesting 2-methylnaphthalene at a dose of 110 mg/kg-body weight/day for 81 weeks exhibited reduced growth (Murata et al. 1997 in USEPA 2007b). Mice orally exposed to BaP for 65 weeks (3.07 mg/kg-body weight/day) were found to have lower survival (Culp et al. 1998 in USEPA 2007b).

Sparse data are available on the effects of PAH ingestion to avian species. Patton and Dieter (1980) reported effects on liver function of mallards fed low-molecular-weight PAHs at the dose of 440 mg/kg-body weight/day for 7 months. European starlings (*Sturnus vulgaris*) gavaged with dimethylbenz(a)anthracene at a dose of 20 mg/kg-body weight/day for 5 days experienced reduced growth (Trust et al. 1994 in USEPA 2007b).

6.1.2 Metals

Metals enter the environment from natural processes and through anthropogenic sources. Chemical, physical, and biological factors influence the potential toxicity of metals. Generally, the bioavailable fraction of total metals concentrations can affect ecological receptors. Metals exhibit a range of binding affinities with both organic (e.g., carbon) and inorganic (e.g., other metals) substances, so the concentration of bioavailable fractions of metals varies. The total concentration of metals is generally not predictive of their bioavailability. Key factors that affect the partitioning and speciation, and thus the bioavailability, of metals include redox conditions, pH,

hardness, organic carbon content, sulfide availability, and percent fines. These factors influence the sequestration, oxidation state, and species of dissolved ions present.

Mercury and lead are two metals that are neither essential nor beneficial to living organisms and can be especially toxic. All measured effects to ecological receptors - including those on survival, growth, reproduction, development, behavior, learning, and metabolism – are adverse, as discussed in more detail below.

6.1.2.1 Mercury

According to Eisler (1987b), most authorities agree on the following six points regarding mercury in the environment (1) mercury and its compounds have no known biological function, and the presence of the metal in the cells of living organisms is undesirable and potentially hazardous; (2) forms of mercury with relatively low toxicity (e.g., inorganic compounds) can be transformed into forms of mercury with high toxicity (i.e. organomercury compounds, such as methylmercury) through biological and other processes; (3) mercury can be bioconcentrated in organisms and biomagnified through food chains; (4) mercury is a mutagen, teratogen, and carcinogen; (5) some species of fish and wildlife contain high concentrations of mercury that are not attributable to human activities; (6) the difference between tolerable natural background levels of mercury and harmful effects in the environment is small.

6.1.2.1.1 Invertebrates

Mercury at comparatively low concentrations adversely affects the reproduction, growth, behavior, metabolism, blood chemistry, osmoregulation, and oxygen exchange of marine and freshwater organisms. In general, the accumulation of mercury by aquatic biota is rapid, and depuration is slow. It is emphasized that organomercury compounds, especially methylmercury, were significantly more effective than inorganic mercury compounds in producing adverse effects and accumulations.

For sensitive marine invertebrates such as hydroids, protozoans, and mysid shrimp, reproduction was inhibited at concentrations between 1.1 and 2.5 ug Hg2+/l; this range was 5 to 71 ug/l for more resistant species of marine invertebrates (Eisler 1987b).

6.1.2.1.2 Fish

In general, the accumulation of mercury in fish is enhanced at elevated water temperatures, reduced water salinity or hardness, reduced water pH, increased age of the fish, and reduced organic matter content of the medium; in the presence of zinc, cadmium, or selenium in solution; after increased duration of exposure; and in the

presence of increased nominal concentrations of protein-bound mercury. Uptake patterns were significantly modified by sex, sexual condition, prior history of exposure to mercury salts, the presence of complexing and chelating agents in solution, dietary composition, feeding niche, tissue specificity, and metabolism; however, trends were not consistent between species and it is difficult to generalize (Eisler 1987b).

6.1.2.1.3 Wildlife

For the protection of sensitive species of birds that regularly consume fish and other aquatic organisms, total mercury concentrations in the prey items should not exceed 100 ug/kg fresh weight. For some birds, adverse effects, predominantly on reproduction, have been associated with total mercury concentrations of (in fresh weight) of 5,000 ug/kg in feather, 900 ug/kg in egg; and with daily intakes of 640 ug/kg body weight (Eisler 1987b).

The significance of elevated mercury levels in tissues of fish and wildlife is not fully understood; some species of marine pinnipeds, for example, normally contain high concentrations of mercury in various tissues without apparent adverse effects. Mercury concentrations in sensitive mammals in excess of 1,100 ug/kg fresh weight of tissue (liver, kidney, blood, brain, hair) or when daily intakes reach 250 ug/kg body weight can cause adverse effects (Eisler 1987b).

6.1.2.2 Lead

Lead adversely affects survival, growth, reproduction, development, and metabolism of most species under controlled conditions, but its effects are substantially modified by numerous physical, chemical, and biological variables. In general, organic lead compounds are more toxic than inorganic lead compounds, food web biomagnification of lead is negligible, and younger, immature organisms are most susceptible to its adverse effects. Uptake of lead by terrestrial plants is limited by the low bioavailability of lead from soils; adverse effects occur only at total concentrations of several hundred parts per million of lead in soil. Lead concentrations in aquatic and terrestrial vertebrates tend to increase with increasing age of the organism, and to localize in hard tissues such as bone and teeth (Eisler 1988).

6.1.2.2.1 Invertebrates

In general, the responses of aquatic invertebrate species to lead differ. In sensitive species the following conclusions can be made: dissolved waterborne lead is more toxic than total lead; organic lead compounds are more toxic than inorganic forms; and lead causes adverse effects on daphnid reproduction (Eisler 1988).

6.1.2.2.2 Fish

Although lead is concentrated by biota from water, no significant biomagnification of lead occurs in aquatic food chains. Increasing waterborne concentrations of lead over 10 ug/l may cause increasingly severe long-term effects on fish and fisheries (Eisler 1988). Lethal solutions of lead can cause a variety of adverse effects to fish including increased mucous formation, anemia, spinal curvature, degeneration of the caudal fin, muscular atrophy, and growth inhibition (Eisler 1988).

6.1.2.2.3 Wildlife

In wildlife, lead can modify the function and structure of kidney, bone, the central nervous system, and the hematopoietic system. It can also produce adverse biochemical, histopathological, neuropsychological, fetotoxic, teratogenic, and reproductive effects.

Remedial goals at five Superfund Sites across the country range from 380 mg/kg to 605 mg/kg of lead in soil, based on robins, ground-feeding insectivores, or earthworm-feeding wildlife (Beyer et al. 2013). Field (bioavailability) data suggest that the remedial goals could be set even higher. For instance, Beyer et al. (2013) concluded a lack of effects to songbirds with lead soil concentrations less than 1,000 mg/kg in the southeast Missouri Lead Mining District. Hansen et al. (2011) showed no effects to robins with lead soil concentrations of up to 1300 ppm of Pb in Idaho's Coeur d'Alene River Basin. In addition, data from the Dutchman Riparian Lands at the Anaconda Superfund Site indicate no adverse effects to robins with lead in soils below 2,000 mg/kg (Texas Tech 2002).

6.1.3 Polychlorinated Biphenyls

PCBs are synthetic organic chemical compounds consisting of chlorine atoms attached to biphenyl. There are 209 configurations of organochlorides with 1 to 10 chlorine atoms. Of the different PCB arrangements and orientations 130 are used commercially. The toxicity of PCBs depends on the structure and number of chlorine atoms.

6.1.3.1 Invertebrates

Aquatic invertebrates assume an important role in the cycling of PCBs within and between ecosystems. Mysid crustaceans from Lake Michigan have a low assimilation efficiency for PCBs and a high efficiency for fecal excretion of ingested PCBs. By vertically migrating to the surface at night, mysids may transport PCBs into the upper regions; the PCBs will continue to recycle through the Lake Michigan ecosystem if the

PCBs are excreted, egested, lost with molts, or if the mysid is consumed by fish (Eisler 1986).

PCB concentrations in freshwater oligochaete worms from the Niagara River in New York State were positively correlated with sediment PCB levels. Uptake of PCBs from the sediment by chironomid (*Chironomus plumosus*) larvae was also directly related to the concentration of PCBs in the sediment. When larvae metamorphosed to adults, PCB compounds were concentrated and transferred from the aquatic to the terrestrial environment. Terrestrial predators that feed on emerging aquatic insects whose larval stage inhabits PCB-contaminated sediments may be exposed to PCBs (Eisler 1986).

In general, aquatic toxicity increases with increasing exposure, crustaceans and younger developmental stages are the most sensitive groups, and lower chlorinated PCBs were more toxic than higher chlorinated PCBs. Bioconcentration factors are generally higher with increasing exposure period, increasing PCB concentration, and with increasing chlorination of PCB congeners (Eisler 1986).

6.1.3.2 Fish

Since PCBs are highly lipophilic, highest concentrations occur in fatty tissues. Other factors known to modify PCB accumulations in aquatic biota include: temperature magnitude and variation; time of incubation and age of larvae; presence of mineral oils on PCB-contaminated substrates; and diet. Of these, diet contributes most of the total PCB body burdens of upper level carnivores.

Considerable interspecies differences exist in the responses of aquatic organisms to PCB loadings, but the following adverse effects are known occur: decreased growth, reproductive toxicity, carcinogenesis, and mutagenesis (Eisler 1986).

6.1.3.3 Wildlife

PCBs have been shown to cause reproductive failure, birth defects, skin lesions, tumors, liver disorders, and death in wildlife. The high lipid solubility of PCBs enables them to bioaccumulate and biomagnify up the food web. Fish are a source of PCBs to wildlife such as mink, which have been found to be very sensitive to PCBs. Similarly, among sensitive avian species, PCBs disrupt normal patterns of growth, reproduction, metabolism, and behavior. Waterfowl have also been shown to be affected by PCBs following dietary exposure (Eisler 1986).

6.1.4 Explosives and Energetics

Limited ecotoxicological information is available for compounds such as tetryl, NG, nitrocellulose, PETN, or other E&E compounds. Toxicity data are available for nitroaromatics: TNT and its metabolites (e.g., 2,4-DNT and 2,6-DNT) as well as the nitramines RDX and HMX, as discussed below.

6.1.4.1 Invertebrates

TNT metabolites can accumulate in the tissues of earthworms and root portions of plants. In terrestrial systems, evidence suggests that nitroaromatics do not bioaccumulate in the above-ground portion of plants or in the body burdens of terrestrial wildlife species.

6.1.4.2 Fish

Available data indicate that E&E compounds have a low potential to bioconcentrate in aquatic organisms given their weak hydrophobicity. However, metabolically formed transformation products (e.g., 2,4-DNT, 2-6-DNT, 4-amino-2,6-DNT) appear to be eliminated at slower rates than their parent compound (TNT).

6.1.4.3 Wildlife

Due to the rapid transformation, excretion, and lack of potential for high, continuous exposure, it is unlikely that nitroaromatic compounds can be transferred between prey and predator species. Few data indicate that environmental exposures of E&E compounds to wildlife are problematic (Sunahara et al. 2009).

6.2 Potential Direct Effects

Direct exposure risks to lower-trophic-level receptors (i.e., plants, terrestrial and aquatic invertebrates, and fish) are evaluated via a comparison of soil, sediment, or surface water EPCs to available ESBs used to represent threshold values below which adverse effects are unlikely. ESB sources include:

- Plants and terrestrial invertebrates:
  - NJDEP ESC table (NJDEP 2009)

  - USEPA (2007) EcoSSLs
  - USEPA's Ecotox Database
  - Oak Ridge National Laboratory (e.g., Efroymson et al.1997a, 1997b)
  - Published peer-reviewed journal articles (e.g., Sverdrup et al. 2003; Talmage et al. 1999)

- Benthic invertebrates:
  - NJDEP ESC table (NJDEP 2009)
  - Mid-Atlantic (Region 3 Biological Technical Assistance Group [BTAG]) Freshwater Sediment Screening Values (USEPA 2006)
  - Published peer-reviewed journal articles (e.g., Persaud et al. 1993)
  - USEPA (2003a) Region 5 ESLs

- Fish:
  - NJDEP ESC table (NJDEP 2009)
  - Mid-Atlantic (Region 3 BTAG) Freshwater Screening Values (USEPA 2006)
  - National Recommended Water Quality Criteria (USEPA 2009)

Section 7 compares soil, sediment, and surface water EPCs to ESBs to characterize potential risk from direct contact exposures.

6.3 Potential Wildlife Effects

USEPA (2007) defines a TRV as a dose (based on laboratory toxicological investigations) above which a particular ecologically relevant effect may be expected to occur in an organism following chronic dietary exposure, and below which it is reasonably expected that such effects will not occur. Rather than deriving one point estimate associated with specific biological effects, both high and low TRVs are identified for each COPEC to bracket a threshold effect level.

The low TRV is a conservative value consistent with a chronic no observed adverse effects level (NOAEL). It represents a conservative dose level at or below which adverse effects are unlikely to occur. Conversely, the high TRV is a less conservative estimator of potential adverse effects, representing a dose level at which adverse effects may occur, and is consistent with a chronic lowest observed adverse effects level (LOAEL). As recommended by USEPA (1997), in the absence of either an NOAEL or LOAEL, the missing value was obtained by extrapolating from the existing value by a factor of 10.

The following literature sources were reviewed for the selection of TRVs for upper-trophic-level wildlife (i.e., birds and mammals):

- USEPA EcoSSLs (USEPA 2003b, 7a, 7b)
- Toxicological studies cited in Sample et al. (1996)
- California Department of Toxic Substances Control (DTSC) BTAG TRVs for Birds and Mammals (DTSC 2002)
- Wildlife Toxicity Assessment Program at the U.S. Army Center for Health Promotion and Preventative Medicine (USACHPPM: 2001a, 2001b, 2001c, 2007, 2012)

When reviewing the toxicological literature and selecting the most appropriate study for TRV development, several factors were considered:

- Taxonomic relationship between the test animal and the receptor species.
- Use of laboratory animals or domesticated species, with preference for wildlife species.
- Toxicological studies where the chemical was administered through diet are preferred over studies using other dosing methods, such as oral gavage or intraperitoneal injection.
- Ecological relevance of the study endpoints. Studies with toxicity endpoints such as reproduction, growth, behavior, and developmental endpoints were targeted. Sensitive endpoints such as reproductive or developmental toxicity were preferentially selected because they are closely related to the selected AEs.

- Long-term studies representing chronic exposure were preferentially selected over short-term, acute studies.

The selected mammalian and avian TRVs are presented in Table 6-1.

7. Ecological Risk Characterization

Risk characterization evaluates potential ecological risk to receptors. For lower-trophic-level terrestrial and aquatic receptors (i.e., terrestrial plants and invertebrates, aquatic invertebrates and fish) potential risks were characterized by comparing soil, sediment, or surface water EPCs to ESBs, which results in an HQ.

For upper-trophic-level avian and mammalian species, resulting dietary doses from the food web models were compared to TRVs to derive the HQs. NOAEL-based HQs (HQ_{NOAEL}) and LOAEL-based HQs (HQ_{LOAEL}) were calculated for both the low and high TRVs, respectively. In general, HQ_{NOAEL} less than one indicate that there are no potential ecological risks and HQ_{LOAEL} less than one suggest that adverse effects are unlikely. With respect to HQ_{LOAEL} greater than 1, USEPA (1994) recommends that HQs be interpreted relative to the assumptions on which the assessment is based. In other words, more conservative exposure and effects assumptions result in a broader range of tolerable HQs.

Given the conservative nature of the assumptions and exposure parameters used in this EE/ERA, the HQ_{LOAEL} provides a more representative indicator of potential ecological risk to upper-trophic-level receptors than the HQ_{NOAEL}. Furthermore, the SI/RI dataset provides general spatial coverage of the Facility, with more focused sampling in source areas. EPCs used in food web models are statistical representations of the dataset (i.e., 95UCLs) that do not consider the spatial context of the data and, therefore, incorporate a conservative bias to the EPCs. Acknowledging the conservative assumptions on which this EE/ERA is based, consideration of the HQ_{LOAEL} is appropriate.

7.1 Terrestrial Receptors

The following section summarizes HQs for terrestrial receptors at the Facility. Tables 7-1 through 7-8 present the results of the terrestrial receptor evaluation. Table 7-9 summarizes the results presented in Tables 7-1 through 7-8.

7.1.1 Soil Invertebrates

Table 7-1 presents HQs based on maximum detected constituent concentrations and 95UCL EPCs estimating potential risks to soil invertebrates. The following table summarizes COPECs with HQs greater than one (based on the 95UCL).

COPEC	Soil Invertebrate HQ (95UCL)
Copper	3
Manganese	6
Vanadium	2
Zinc	2

7.1.2 Plants

Table 7-2 presents HQs based on maximum detected constituent concentrations and 95UCL EPCs estimating potential risks to terrestrial plants. The following table summarizes COPECs with HQs greater than one (based on the 95UCL).

COPEC	Terrestrial Plant HQ (95UCL)
Antimony	2
Arsenic	2
Chromium	23
Copper	4
Lead	12
Manganese	3
Mercury	46
Selenium	5
Vanadium	19
Zinc	2

7.1.3 Wildlife

Potential ecological risk was evaluated for three avian receptors (Tables 7-3, 7-4, and 7-5) and three mammalian receptors (Tables 7-6, 7-7, and 7-8). Table 7-9 summarizes the terrestrial receptor HQs.

7.1.3.1 Birds

The evaluation of potential ecological risks for American robin, northern bobwhite, and red-tailed hawk indicates the following:

- Three COPEC HQ_{LOAELs} exceed 1 for American robin.
- COPEC HQ_{LOAELs} are less than or equal to 1 for northern bobwhite.
- COPEC HQ_{LOAELs} are less than or equal to 1 for red-tailed hawk.

The following table summarizes COPECs with HQs greater than 1.

COPECs	American Robin	Northern Bobwhite	Red-Tailed Hawk
	HQ_{LOAEL}		
Total PCBs	3	≤1	≤1
Copper	3	≤1	≤1
Lead	25	≤1	≤1

7.1.3.2 Mammals

The evaluation of potential ecological risks for short-tailed shrew, white-tailed deer, and red fox indicates the following:

- One COPEC HQ_{LOAEL} exceeds 1 for short-tailed shrew.
- COPEC HQ_{LOAELs} are less than or equal to 1 for white-tailed deer.
- COPEC HQ_{LOAELs} are less than or equal to 1 for red fox.

The following table summarizes COPECs with HQs greater than 1.

COPECs	Short-Tailed Shrew	White-Tailed Deer	Red Fox
	HQ_{LOAEL}		
Lead	3	≤1	≤1

7.2 Aquatic Receptors

The following section presents HQs for aquatic receptors in the Northern and Southern Drainage Areas. HQs were calculated for benthic invertebrates, aquatic life (fish and aquatic invertebrates), tree swallow, great blue heron, mallard duck, little brown bat, mink, and muskrat. Tables 7-10 through 7-27 present COPEC HQs for each receptor. Table 7-28 summarizes HQs for aquatic wildlife receptors.

7.2.1 Northern Drainage Area

The Northern Drainage Area encompasses several aquatic habitats, including Duck Pond, Shooting Pond, and various tributaries. Results of the evaluation for the Northern Drainage Area are presented in Tables 7-10 through 7-18.

7.2.1.1 Benthic Invertebrates

Table 7-10 presents HQs based on maximum detected constituent concentrations and 95UCL EPCs estimating potential risks to benthic invertebrates in the Northern

Drainage Area. The following table summarizes COPECs with HQs greater than one (based on the 95UCL).

Northern Drainage Area	
COPEC	**Benthic Invertebrate HQ (95UCL)**
Pyrene	2
Arsenic	2
Cadmium	2
Copper	4
Lead	6
Mercury	4
Zinc	3

7.2.1.2 Aquatic Plants

Table 7-11 presents HQs estimating potential risks to aquatic plants in the Northern Drainage Area. Metals are the only risk drivers for aquatic plants (i.e., have HQs greater than 1). The following table summarizes COPECs with HQs greater than one (based on the 95UCL).

Northern Drainage Area	
COPEC	**Aquatic Plant HQ (95UCL)**
Chromium	21
Lead	2
Mercury	3
Zinc	2

7.2.1.3 Fish and Aquatic Invertebrates

Table 7-12 presents HQs estimating potential risks to fish and aquatic invertebrates in the Northern Drainage Area. Northern Drainage Area surface water COPECs are limited to metals. HQ calculations used dissolved metals concentrations to estimate potential risks to fish and aquatic invertebrates. The following table summarizes COPECs with HQs greater than one (based on the 95UCL).

Northern Drainage Area	
COPEC	**Fish and Aquatic Invertebrate HQ (95UCL)**
Copper	3
Lead	4

7.2.1.4 Birds

The evaluation of potential ecological risks for tree swallow, great blue heron, and mallard duck using aquatic habitats in the Northern Drainage Area, as presented in Tables 7-13, 7-14, and 7-15, indicates the following:

- Two COPEC HQ_{LOAELs} exceed 1 for tree swallow.
- COPEC HQ_{LOAELs} are less than or equal to 1 for great blue heron.
- COPEC HQ_{LOAELs} are less than or equal to 1 for mallard duck.

The following table summarizes COPECs with HQs greater than 1.

Northern Drainage Area			
COPECs	**Tree Swallow**	**Great Blue Heron**	**Mallard Duck**
	HQ_{LOAEL}		
Copper	7	≤1	≤1
Lead	10	≤1	≤1

7.2.1.5 Mammals

The evaluation of potential ecological risks for little brown bat, mink, and muskrat using aquatic habitats in the Northern Drainage Area, as presented in Tables 7-16, 7-17, and 7-18, indicates the following:

- One COPEC HQ_{LOAEL} exceeds 1 for little brown bat.
- COPEC HQ_{LOAELs} are less than or equal to 1 for mink.
- COPEC HQ_{LOAELs} are less than or equal to 1 for muskrat.

The following table summarizes COPECs with HQs greater than 1.

Northern Drainage Area			
COPECs	**Little Brown Bat**	**Mink**	**Muskrat**
	HQ_{LOAEL}		
Copper	3	≤1	≤1

7.2.2 Southern Drainage Area

The Southern Drainage Area drains the majority of the former operational area of the Facility. Tables 7-19 through 7-27 present results of the evaluation for the Southern Drainage Area.

7.2.2.1 Benthic Invertebrates

Table 7-19 presents HQs based on maximum detected constituent concentrations and 95UCL EPCs estimating potential risks to benthic invertebrates in the Southern Drainage Area. The following table summarizes COPECs with HQs greater than one (based on the 95UCL).

Southern Drainage Area	
COPEC	**Benthic Invertebrate HQ (95UCL)**
Tetrachloroethene	10
2,4-DNT	7
Acenaphthene	382
Acenaphthylene	872
Anthracene	213
Benzo(a)anthracene	199
Benzo(a)pyrene	104
Benzo(g,h,i)perylene	119
Benzo(k)fluoranthene	103
Chrysene	138
Dibenzo(a,h)anthracene	73
Fluoranthene	198
Fluorene	270
Indeno(1,2,3-cd)pyrene	2
Naphthalene	89
Phenanthrene	542
Pyrene	305
Arsenic	3
Copper	3
Lead	126
Manganese	5
Mercury	8

7.2.2.2 Aquatic Plants

Table 7-20 presents HQs estimating potential risks to aquatic plants in the Southern Drainage Area. Metals and PAHs are the primary risk drivers for aquatic plants (i.e., have HQs greater than 1). The following table summarizes COPECs with HQs greater than one (based on the 95UCL).

Southern Drainage Area	
COPEC	**Aquatic Plant HQ (95UCL)**
Acenaphthylene	2
Anthracene	2
Benzo(a)anthracene	6
Benzo(a)pyrene	4

Southern Drainage Area	
COPEC	**Aquatic Plant HQ (95UCL)**
Benzo(g,h,i)fluoranthene	2
Benzo(k)fluoranthene	2
Chrysene	5
Phenanthrene	7
Pyrene	3
Chromium	26
Lead	38
Manganese	12
Mercury	6
Selenium	3
Thallium	3

7.2.2.3 Fish and Aquatic Invertebrates

Table 7-21 summarizes potential risks to fish and aquatic invertebrates in the Southern Drainage Area. HQs were calculated using dissolved COPEC concentrations when available. In the absence of dissolved COPEC concentrations, total concentrations were used as a conservative measure. The following table summarizes COPECs with HQs greater than one (based on the 95UCL).

Southern Drainage Area	
COPEC	**Fish and Aquatic Invertebrate HQ (95UCL)**
Aluminum[1]	8
Manganese[1]	11
Lead	3

Note:
[1] HQs for aluminum and manganese calculated using total concentration due to a lack of dissolved data.

7.2.2.4 Birds

The evaluation of potential ecological risks for tree swallow, great blue heron, and mallard duck using aquatic habitats in the Southern Drainage Area, as presented in Tables 7-22, 7-23, and 7-24, indicates the following:

- Four COPEC HQ_{LOAELs} exceed 1 for tree swallow.
- One COPEC HQ_{LOAEL} exceeds 1 for great blue heron.
- One COPEC HQ_{LOAEL} exceeds 1 for mallard duck.

The following table summarizes COPECs with HQs greater than 1.

Southern Drainage Area			
COPECs	**Tree Swallow**	**Great Blue Heron**	**Mallard Duck**
	HQ_{LOAEL}		
Fluoranthene	3	≤1	≤1
Copper	4	≤1	≤1
Lead	224	24	2
Selenium	2	≤1	≤1

7.2.2.5 Mammals

The evaluation of potential ecological risks for little brown bat, mink, and muskrat using aquatic habitats in the Southern Drainage Area, as presented in Tables 7-25, 7-26, and 7-27, indicates the following:

- Five COPEC HQ_{LOAELs} exceed 1 for little brown bat.
- One COPEC HQ_{LOAEL} exceeds 1 for mink.
- COPEC HQ_{LOAELs} are less than or equal to 1 for muskrat.

The following table summarizes COPECs with HQs greater than 1.

Southern Drainage Area			
COPECs	**Little Brown Bat**	**Mink**	**Muskrat**
	HQ_{LOAEL}		
Fluoranthene	6	≤1	≤1
Pyrene	3	≤1	2
Copper	2	≤1	≤1
Lead	26	8	≤1
Selenium	2	≤1	≤1

7.3 PCDD/F Risk Characterization

Appendix D presents an ERA specific to PCDD/F in soil in former burning areas of the Facility. General site characterization sampling in the SI/RI did not include analysis for PCDD/F. Focused PCDD/F sampling was conducted in areas of the site that supported historical burning activities and in response to a request by NJDEP. PCDD/F data were evaluated separately given the differences in size and spatial coverage of the datasets (i.e., Facility-wide [more than 1,000 acres] versus four discrete former burning areas totaling less than 10 acres).

Food web modeling was conducted for each of the terrestrial receptors evaluated in this EE/ERA using congener-specific 95UCLs for PCDD/F and a toxicity equivalency quotient (TEQ)-based approach (Van den Berg et al. 1998, 2006). Species-specific exposure factors used in the food web model for PCDD/F remain consistent with those in the overall ERA.

As summarized in the table below, food web models for PCDD/F in soil resulted in HQs less than 1 for all ecological receptors evaluated. These results indicate that potential ecological risk attributable to PCDD/F in soil in former burning areas of the Facility is unlikely.

PCDD/F – Former Burning Area Soil	
Receptors	**HQs**
American robin	≤1
Red-tailed hawk	≤1
Bobwhite quail	≤1
Short-tailed shrew	≤1
Red fox	≤1
White-tailed deer	≤1

7.4 Ecological Risk Characterization Discussion

The risk characterization compares COPEC concentrations in potential receptors to conservative benchmark values identified in Section 6. To characterize potential ecological risk to populations using the exposure areas, consideration of benchmark values below which significant effects are not expected (i.e., LOAEL-based TRVs) to occur is appropriate.

7.4.1 Terrestrial Exposures

Potential risks to terrestrial receptors were evaluated over one Facility-wide soil exposure area. Metals including lead, chromium, vanadium, and copper in soil present the highest potential for risk to terrestrial receptors via both direct exposure and food-web transfer. Metals are commonly associated with historical fill materials (e.g., fly ash, bottom ash, slag), which were byproducts of the local iron mining and processing industry and imported to the Facility as fill to support Facility development in the early 1900s.

Total PCB HQs exceeded 1 in the food web models for American robin (HQ = 3). The appearance of total PCBs to cause potential risk is an artifact of one sample result (150 mg/kg at one location in the Maintenance Area) in a dataset where PCBs were

detected in 141 of 451 samples (a 31 percent frequency of detection). The sum of the detected PCB concentrations across the 141 samples totals 254 mg/kg, indicating that almost 60 percent of the detected mass Facility-wide is attributable to one sample location (150/254 = 0.59). Absent this sample location, total PCB HQs would be less than 1. Considering this spatial bias, potential risk to terrestrial receptors at the Facility from PCBs is unlikely.

Overall, potential risks to terrestrial receptor populations related to COPECs other than lead are low.

7.4.2 Aquatic Exposures

Aquatic exposure pathways were evaluated by drainage area. Beyond the distinct surface water drainages, each exposure area possesses a unique developmental and operational history. For instance, although the Northern Drainage Area consists of altered land and contains some discernable filled areas, the majority of the historical fill imported to the Facility was used to raise the ground surface elevation and support development within the Southern Drainage Area. Due to its earlier development in the Facility's history, the Southern Drainage Area also housed the largest concentration of historical operations and facility support services (e.g., Maintenance Area, powerhouse). These historical differences are evident in aquatic HQs from these exposure areas, as discussed below.

7.4.2.1 Northern Aquatic Drainage Area

Copper and lead emerge as having the highest potential for risk in the Northern Drainage Area. Copper and lead concentrations in sediment and surface water yielded HQs greater than one for direct contact exposure scenarios (i.e., benthic invertebrates, and fish and aquatic invertebrates) as well as food web modeling for an upper-trophic-level aquatic bird (i.e., tree swallow). Lead represents the only COPEC with an HQ greater than 10 in the Northern Drainage Area.

Nickel, zinc, and NG have slightly lower HQs than copper and lead. Metals often exist in sediment in one or more insoluble forms (e.g., metal selenides [including copper sulfide and/or zinc sulfide]), thus limiting bioavailability (ATSDR 2003). The presence of metallic complexes in organic-rich sediment would limit the bioavailability of these constituents. The presence of NG to cause potential risk assumes 100 percent bioavailability. In reality, NG occurs at the Facility as a component of solid smokeless

powder grains, and thus is bound in a solid, insoluble matrix with likely limited bioavailability.

7.4.2.2 Southern Aquatic Drainage Area

A similar group of metals emerge as having the greatest potential for ecological risk in the Southern Drainage Area, as well as PAHs. Lead HQs are at least one order of magnitude greater than other metals for both direct contact and food web transfer exposure scenarios. Potential direct contact risks are limited to sediment exposure by benthic invertebrates, with PAHs and lead presenting the greatest potential for risk. Copper, selenium, fluoranthene, and pyrene also pose potential risk to upper-trophic level aquatic wildlife.

7.4.3 COPECs with the Greatest Potential for Risk

The emergence of lead to present potential risk in multiple media and exposure scenarios is not unexpected given the presence of lead in commerce, historical fill, and use of lead in historical Facility operations. Lead possesses non-conductive/non-sparking properties and several buildings were partially lined with lead, as were material conveyances (i.e., pipes, culverts, vessels). Lead used onsite existed primarily in the inorganic form, which is not readily bioavailable and not expected to bioaccumulate (Eisler 1988).

Vegetated wetland features make up the majority of aquatic habitat in the Southern Drainage Area, with intermittent ditches and other drainage features draining wetlands to the large southern wetland complex. Sediment in these wetland habitats is rich in organics (Southern Drainage Area total organic carbon average of 5.8 percent, with a maximum value of 43 percent and many values between 10 and 30 percent in the southern wetland complex). The breakdown of these organics consumes oxygen and results in anoxic sediment conditions.

Together, anoxic (reducing) conditions and available organic carbon yield an environment favorable for binding of metals, rendering them unavailable for uptake by organisms (ITRC 2011). Lead (as well as other divalent metals: copper, cadmium, nickel, zinc, and silver) is subject to binding/ sequestration in the presence of acid volatile sulfide (AVS), often found in anoxic wetland sediment. While food web modeling results identify potential risks related to lead in soil and sediment, the conservative assumptions on which the HQs are based, particularly those related to bioavailability, likely overestimate potential risks. The inorganic forms of lead used

onsite during historical operations, and reducing onsite aquatic habitat conditions likely constrain lead bioavailability, as do other habitat conditions that facilitate metals sequestration (e.g., high organic carbon content).

Historical fill is known to contain PAHs and metals (N.J.A.C. 7:26E – NJDEP TRSR). Historical fill materials were used during early development of the Facility to raise ground surface elevations. The Southern Drainage Area, where both PAHs and metals appear more prevalent in sediment, drains much of the former operational area of the Facility where large amounts of historical fill have been mapped (Hercules 2007, 2016). Surface water drains through shallow ditches cut into the filled valley floor. PAHs and metals in Southern Drainage Area sediments may be influenced by non-Facility-related sources as well. The RI has documented these constituents in stormwater runoff from adjacent roadways (i.e., Route 46 and Howard Boulevard) that directly discharge to a series of ditches in the Southern Drainage Area (Hercules 2007). Physical and chemical conditions onsite, like those outlined above for lead, likely limit bioavailability of these potential secondary risk drivers.

The Facility history, previous reports (Hercules 2007), and CSM (Section 3.1) establish links between the terrestrial and aquatic exposure areas used in this EE/ERA. The RIRs (Hercules 2007) identified lead as a “frequent exceedance” constituent in soil, sediment, and surface water. Thus, the appearance of similar constituents (lead in particular) as potential risk drivers confirms historical findings and further informs an understanding of COPEC fate, transport, and exposure pathways.

8. Uncertainty Analysis

This EE/ERA presents an initial, conservative evaluation of potential risks to ecological receptors by incorporating upper-bound estimates of potential effects and exposure. Therefore, HQs greater than 1 are not considered to be an indication of actual risk, but only that the potential for adverse effects cannot be ruled out. In a risk assessment, a substantial level of uncertainty exists. Sources of uncertainty include:

- Natural variability of ecological systems
- Incomplete knowledge of site-specific fate and transport mechanisms and biological processes
- Use of organism-specific TRVs to evaluate potential population level effects
- Use of generic bioaccumulation factors and models to estimate uptake of COPECs at the Facility

Uncertainties potentially influencing results of the EE/ERA are briefly described below.

8.1 Complexity of Natural Systems

Natural systems are complex and involve the interaction of several physical, chemical, and biological elements. The EE/ERA uses simplifying assumptions to attempt to model these interactions. Direct measurements of COPEC concentrations are used along with information from scientific literature to model the interactions that may be occurring in natural systems. The assumptions made and models used, and how well or poorly these assumptions and models reproduce the interactions taking place in the natural system, introduce uncertainty in the EE/ERA. An effort has been made to use conservative assumptions to bias potential risk to ecological receptors toward overestimation.

8.2 Data Uncertainty

The ERA makes use of the SI/RI dataset collected between 1999 and 2013. These data were collected in support of general site characterization activities; not specifically to assess ecological risk. As such, certain limitations are inherent in the existing dataset that contribute uncertainty to the results of the EE/ERA.

The overall approach of the EE/ERA focuses the assessment on areas of the Facility where potential ecological risk is uncertain. To achieve this focus, data representative of undeveloped areas outside the Remedial Area boundary and data from areas where Hercules is committed to active remediation (Areas of Presumed Remedial Action) to address Facility-related influences were removed from the ERA dataset. The evaluation of potential ecological risk at the Facility using the parsed dataset introduces uncertainty to the process. However, the commitment to implement a remedy protective of human health and the environment in Areas of Presumed Remedial Action addresses ecological risk with a greater degree of certainty than estimating risks via the methods outlined in this EE/ERA. The undeveloped areas beyond the Remedial Area boundary were defined using the SI/RI dataset and a comparison to remediation standards protective of human health. Appendix C quantitatively evaluates these data in the context of potential ecological risk. Addressing these areas via remediation and quantitative assessment reduces potential uncertainties.

Data collected during the SI/RI were analyzed using the standard/commonly accepted analytical method and associated method detection limits. In many cases, the non-detect reporting limits are greater than the ESBs used in this EE/ERA. As such, the presence (and concentration) of those constituents at or below the ESB is unknown, as is the associated contribution to total potential risk. However, given the large datasets that consist of hundreds of samples collected over multiple sampling timeframes, the exclusion of data qualified as non-detect does not impede the spatial evaluation of potential risk across the facility.

Samples collected early in the SI/RI process were analyzed for a full constituent list per regulatory requirements. As the investigation progressed, the analyte list was reduced based on previous findings to focus on Facility-related constituents. Presumably, if the constituents were not analyzed for, detections were below screening standards at the time those decisions were made. This situation contributes a degree of uncertainty to the EE/ERA.

Analytical data resulting from a preliminary investigation of free or residual product (i.e., motor oil, diesel fuel, No. 6 fuel oil, gasoline, hydrocarbons as mineral spirits, and total petroleum hydrocarbons) were reported for six samples in the database. Results were non-detect for these analytes (except motor oil). Motor oil has not been carried forward as a COPEC because it represents a combination of individual PAH constituents represented elsewhere in the dataset, and toxicology information specific to motor oil is not available to support food web modeling.

Finally, the SI/RI sediment dataset represents the 0- to 1-foot sample interval. The BAZ in sediment is generally considered the 0- to 0.5-foot interval, and occasionally extends to the 1 foot-depth based on geochemical conditions in the sediment (e.g., redox potential). Data from the deeper component of the interval may not represent the most recently deposited sediment and/or the BAZ, and may have been deposited decades ago during the Facility's operational history. In this case, the COPEC concentrations in sediment at the sampled depth may overestimate potential ecological risk and reflect an interval of the substrate uninhabited by infaunal biota. Similarly, anoxic sediment conditions, more likely to occur at depth than at the surface, retard the degradation process of COPECs. Thus, COPEC concentrations in sediment between 0.5 and 1 foot may overestimate COPEC concentrations in surface sediment. The correlation of constituent concentrations in sediment between 0.0 to 0.5 and 0.5 to 1 foot is unknown and contributes a degree of conservatism and uncertainty to the EE/ERA.

8.2.1 COPEC Screening Process

The COPEC screening process involved a sequential analysis of the dataset to retain constituents for consideration in the EE/ERA. Constituents detected in at least five samples and that exceeded their respective benchmark (or lacked a screening benchmark) were retained as COPECs. Constituents that were detected in less than five samples were not retained as COPECs. Table 8-1 summarizes statistical information for the constituents with low detection frequencies in each exposure medium. Although some of these constituents have detection limits that are higher than associated screening values, many of these constituents are volatile, can be associated with laboratory techniques, can be tentatively identified compounds, and/or have limited toxicity. Given the size of the site characterization dataset, elimination of these infrequently detected constituents contributes negligible uncertainty to the assessment.

COPEC screening considered the number of detects and maximum detected concentration. Based on the comprehensive nature of the dataset, non-detect reporting limits were not considered in the COPEC selection process. As such, some constituents that were not retained as COPECs possessed a maximum non-detect reporting limit greater than the associated ESB. Thus, the potential exists for this process to underestimate risk. However, inclusion of these data by relying on assumptions regarding the actual concentration that may be present would also introduce significant uncertainty to the assessment, and the overall size and comprehensive nature of the dataset limit the likelihood of these false negatives.

Potential risk associated with several constituents could not be quantitatively evaluated because screening benchmarks were unavailable. A list of commonly used ESB sources were evaluated, as well as constituent- and class-specific peer-reviewed literature and publically available documents, without identifying an appropriate ESB. Little is known about the environmental fate, transport, and/or toxicity for many of these constituents; or the information available indicates that these constituents are unlikely to pose significant risk to ecological receptors. Limited toxicity and/or scientific information for certain constituents (i.e., beryllium, methanol, thallium, and nitrocellulose in sediment) results in some uncertainty, and the magnitude of any potential for risk is unknown.

Beyond a comparison of constituent concentrations to ESB, constituent-specific information was used to further refine the list of COPECs carried through the EE/ERA, as presented below:

- As described in Section 4.1.2, some constituents appeared on multiple analyte lists, resulting in multiple data points at the same location. A combination of technical and regulatory information was used to select the more representative (e.g., accurate and precise) data for use in the EE/ERA.

- The maximum detected concentration of aluminum exceeded its associated generic ESB. Risk guidance (USEPA 2003b) indicates that soluble aluminum in soil can pose a potential risk to ecological receptors, and that soil pH below 5.5 dictates aluminum solubility and therefore bioavailability. As such, information regarding the pH of Facility soil was evaluated prior to retaining aluminum as a COPEC. The 95UCL calculated for Facility soil from field (pH = 5.8) and laboratory samples (pH = 6.1) was greater than 5.5; therefore, aluminum was not retained as a COPEC.

8.2.2 Exposure Point Concentrations

The COPEC screen identified COPECs based on the maximum detected constituent concentration. EPCs used in the food web models were calculated using the 95UCL (or maximum detected concentration in the absence of sufficient data for statistical analysis). The size of the available datasets introduces uncertainty to the development of one point concentration representative of exposures across the entire exposure area. For many COPECs, orders of magnitude differences occur when calculating HQs using the maximum concentration and the 95UCL (Tables 6-1, 6-2, 6-10, and 6-18). While the direction and magnitude of this uncertainty are not completely measurable

across receptor groups, the use of the maximum concentration or the 95UCL may overestimate risk.

8.2.3 Exposure Areas

Field conditions and observations were used to select aquatic exposure areas. Historical drawings provided information on the location of Facility drainage features. Some historical drainage patterns onsite were altered during decommissioning and demolition activities. Intermittent ditches and swales drained stormwater runoff from former process areas. The altered topography following demolition and the increase in the rate of evaporation and transpiration due to the successional vegetation currently occupying these areas, and the potential inability for them to support a benthic invertebrate community, contributes some uncertainty to the evaluation of sediment samples collected in ditches and swales. For the EE/ERA, samples collected from ditches and swales were retained as sediment samples. This represents a conservative approach because sediment screening benchmarks protective of benthic invertebrate communities are generally much lower than those of soil. The uncertainty associated with this decision may result in an overestimation of risk.

The habitat quality within each exposure area varies. In general, natural areas and those forested areas that served as buffers between historical operational areas provide higher quality habitat, while the former operational areas consist of disturbed lands with early successional vegetation and provide habitat of lesser quality. The quality of the habitat is often consistent with the quality of the environmental media within. That is, areas of poorer quality habitat often coincide with areas of former Facility operations and influences, resulting in higher COPEC concentrations and a greater characterization sample density. Conversely, COPEC concentrations and sampling density in buffer areas that often provide higher quality habitat are generally lower. Food web models assume that wildlife receptors spend equal amounts of time in all areas of the Facility. In reality, wildlife receptors may prefer the higher quality habitat for cover, forage resources, and other ecological advantages that it affords. This assumption inherent to the food web models may overestimate risk.

8.2.4 Exposure Parameters

Risk assessment requires assumptions regarding the extent to which organisms are exposed to constituents at the Facility. The exposure parameters used to conduct food web modeling for birds and mammals were selected to represent conservative feeding strategies for each of the selected receptors. These exposure parameters are not

Facility-specific, although an attempt was made to reflect actual Facility conditions to the extent possible. For example, relevant information about regional diet was considered. Site-specific habitat characteristics (e.g., availability, distribution, and quality of food) influence feeding strategies and, therefore, exposure parameters, resulting in uncertainty attributable to the use of generic exposure parameters.

Site use factors were conservatively set at one, indicating that receptor species spent their time foraging exclusively at the Facility. The approach fails to acknowledge receptor-specific behaviors such as seasonal migration and large foraging ranges, and thus may overestimate potential risks.

In addition, receptor species' dietary composition was conservatively assumed to consist of one prey item representing a particular feeding guild. Therefore, herbivorous species were assumed to eat 100 percent plants, insectivorous species 100 percent insects, and carnivorous species 100 percent animal tissue. Further, representative prey item selection was conservative, selecting those prey items more prone to accumulation of COPECs. In particular, the American robin was assumed to eat only invertebrates, with earthworms representing the invertebrate prey items because worms represent the portion of the robin's diet that is most likely to be associated with bioaccumulative compounds. In reality, invertebrates comprise only a fraction of the robin's diet, with worms making up a percentage of that fraction. As a result, the species-specific exposure parameters, and ultimately the dose estimates, presented in this EE/ERA may overestimate actual exposures. More realistic dietary percentages for tree swallow and American robin are provided below:

Receptor	Invertebrates (%)	Vegetation (%)	Reference
Tree swallow	80	20	Beal 1918
American robin	37.5	62.5	USEPA 1993b

8.2.5 Uptake Factors

The EE/ERA used literature-derived BAFs and BSAFs to estimate tissue concentrations for soil/sediment invertebrates, plants, small mammals, and fish tissue. For soil, literature-based BAF models from USEPA (1999 and 2007) were used. For sediment, BSAF data were obtained from the USACE BSAF database (USACE ERDC EL 2011).

Non-site-specific and modeled accumulation factors introduce a high degree of uncertainty. Furthermore, BSAFs are highly variable and dependent upon the species

tested, lipid content of the organism, and organic carbon content of the sediment. Values selected from the USACE BSAF database are based on data collected at different sites and across ranges of species that likely do not reflect uptake under the conditions at the Facility. To date, only non-polar organic compounds have been shown to uphold the relationship between sediment organic content and tissue lipids, and even these constituents show a wide variation in BSAF values (USACE ERDC EL 2011). The direction and magnitude of this uncertainty are not measurable.

8.3 Effects Uncertainty

8.3.1 Bioavailability

Per regulatory guidance (USEPA 1997, NJDEP 2015), this EE/ERA conservatively assumes that COPECs are 100 percent bioavailable to receptors, which is generally not realistic for most constituents, particularly in soil and sediment. The bioavailability of constituents depends on the form originally released, as well as various physical and chemical characteristics of the medium (e.g., soil or sediment). Potential interactions among metals may also influence their bioavailability and uptake to terrestrial organisms.

For example, when absorbed by invertebrates, metals such as lead have been shown to form detoxification products by binding special proteins called metallothioneins (MTs) or by forming salt particulate bodies with sulfur or calcium, sometimes termed metal-rich granules (MRGs). When associated with MTs or MRGs, metals would not cause adverse effects to the organism. There is some evidence indicating that metals within MRGs are not available for trophic transfer to other organisms (USACE ERDC EL 2011; Adams et al. 2010).

Concentrations of certain metals in sediment pore water have been correlated with biological effects (DiToro et al. 1991). For several divalent metals, a key partitioning phase controlling cationic metal activity and toxicity in sediments appears to be AVS (DiToro et al. 1990, 1991; Ankley et al. 1996). Simultaneously extracted metal (SEM) and AVS measurements can be made to assess the potential bioavailability of SEM (including cadmium, copper, lead, nickel, and zinc). In general, the bioavailability of metals decreases as conditions become more reducing and pH, hardness, organic carbon, percent fines, and AVS increase. As discussed in Section 7.4, sediment conditions in aquatic habitats onsite are favorable for metals sequestration.

8.3.2 Explosive and Energetic Compounds

Despite more than 100 years of E&E material production onsite, potential ecological risks related to E&E compounds are generally low. There are several reasons that this could be possible:

- TNT, the most prominent E&E constituent identified in the SI/RI, occurs in one of the Areas of Presumed Remedial Action that will undergo remediation. As such, the TNT data representing the most substantially influenced areas of the Facility were not considered in the EE/ERA. The chemical and biological breakdown of TNT is a source of the DNT and amino-DNT constituents onsite. Thus, these constituents are frequently co-located and, by excluding areas of highest TNT concentrations, the highest concentrations of DNTs and amino-DNTs were removed as well.

- Most E&E compounds will degrade via natural weathering and through time. The Facility was decommissioned between 1996 and 2003; therefore, natural recovery has been occurring at the Facility. In addition, E&E compounds are capable of being metabolized by biological processes and in ecological tissues.

- Many E&E compounds that were detected at the Facility were screened out of media during the COPEC screen. This indicates that E&E compounds have relatively low toxicity to organisms, resulting in higher ESBs.

- Several E&E compounds were carried through the COPEC screen and into the food web models because they lacked ESB. They were then modeled to upper-trophic-level receptors but, because they lack bioaccumulative properties, could not be assessed further.

As a result of the low toxicity/low bioavailability and propensity of E&Es to be metabolized or degraded over time, most E&Es released at the Facility are unlikely to pose potential ecological risk. However, there is some uncertainty for E&E constituents with laboratory detection limits greater than ESB, and/or those for which ESB are unavailable. The effect of this uncertainty on the EE/ERA is unknown.

8.3.3 Toxicity Reference Values

This EE/ERA uses toxicological data that were collected on an individual basis, not at the population level. Therefore, the HQs represent potential risks to single species of

organisms, not to a population or community. However, potential risks were extrapolated to include the entire population as a whole. In general, species selected for study are those with a high degree of sensitivity to the chemical exposure being evaluated, resulting in benchmarks that are protective of sensitive species and conservative when used for the general population.

In addition, the majority of the evaluated toxicity data were derived from laboratory studies conducted in settings that do not mimic true field conditions. Laboratory studies typically control various factors in order to isolate one particular parameter. Although such controlled experiments make it simpler to interpret isolated parameters or relationships, uncertainty is associated with assuming that laboratory exposure conditions are equivalent to in-field exposure conditions. TRVs are typically based on laboratory dosing studies in which highly soluble forms of the COPECs were used. As a result, these toxicity estimates can overestimate the bioavailability, uptake, and ultimate toxicity of a particular COPEC. However, for the EE/ERA, it is assumed that the TRVs represent actual exposures to the receptors evaluated. As such, potential risks are likely overestimated.

The TRV available for PCBs is based on an individual Aroclor (Aroclor 1254). Receptor species sensitivity and associated toxicity varies by Aroclor based on the degree and location of chlorination in the molecular structure. The TRV from Sample et al. (1996) selected for use in this EE/ERA is based on studies using Aroclor 1254, which dominated the literature at that time. Aroclor 1254 is the most prevalent Aroclor identified onsite; therefore, using this TRV for total PCBs is appropriate for this dataset.

9. Conclusions and Recommendations

This EE/ERA provides a conservative assessment of potential ecological risk, focusing on former operational influences in historically developed areas of the Facility. The risk characterization for lower-trophic-level receptors compares COPEC concentrations in exposure media to ESBs. For upper-trophic-level wildlife receptors, the estimated exposure (i.e., daily dietary dose) of each COPEC to potential wildlife receptors is compared to literature-based TRVs. In certain areas, additional evaluations of potential risks refine the conservative nature of the assessment and provide context to the results.

9.1 Conclusions

An interpretation of HQ values relative to each AE and ME is presented below.

- AE 1. Could direct contact with COPECs in Facility soil affect the structure, function, and/or survival of the terrestrial plant community?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to terrestrial plant communities by exposure to COPECs at the Facility are possible.

  – This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

  – This conclusion is supported by the following ME:

    ✓ HQs resulting from a comparison of soil COPEC concentrations to ESBs protective of terrestrial plants were greater than 1 for 10 COPECs; HQs

ranged from 2 to 46, with the greatest potential for risk from the metals mercury (46)[5], chromium (23), and vanadium (19).

- AE 2. Could direct contact with COPECs in Facility soil affect the structure, function, and/or survival of the terrestrial invertebrate community?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to terrestrial invertebrate communities by exposure to COPECs at the Facility are unlikely.

  – This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

  – This conclusion is supported by the following ME:

    ✓ HQs resulting from a comparison of soil COPEC concentrations to ESBs protective of terrestrial invertebrates were less than 1 for COPECs, with the exception of copper (3), manganese (6), vanadium (2), and zinc (2).

- AE 3. Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of herbivorous avian and mammal populations?

  – Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to herbivorous avian and mammal populations by exposure to COPECs at the Facility are unlikely.

  – This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective)

[5] Calculated HQs are presented in parentheses next to each COPEC to show magnitude of potential to cause adverse effects; in other words, the larger the number, the greater the likelihood that adverse effects are possible.

assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

- This conclusion is supported by the following MEs:

  - ✓ HQ_{LOAELs} for northern bobwhite, an herbivorous bird, are less than 1.
  - ✓ HQ_{LOAELs} for white-tailed deer, an herbivorous mammal, are less than 1.

- AE 4. Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of insectivorous avian and mammal populations?

  - Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to insectivorous avian populations by exposure to COPECs at the Facility are possible, but adverse effects to mammal populations by exposure to COPECs at the Facility are unlikely.

  - This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

  - This conclusion is supported by the following MEs:

    - ✓ HQ_{LOAELs} for American robin, an insectivorous bird, are less than 1, with the exception of total PCBs (3), copper (3), and lead (25).

    - ✓ HQ_{LOAELs} for short-tailed shrew, an insectivorous mammal, are less than 1, with the exception of lead (3).

- AE 5. Could food-web transfer of COPECs in Facility soil adversely affect reproductive success or survival of carnivorous avian and mammal populations?

  - Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to carnivorous avian and mammal populations by exposure to COPECs at the Facility are unlikely.

- This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

- This conclusion is supported by the following MEs:

  - ✓ HQ_{LOAELs} for red-tailed hawk, a carnivorous bird, are less than or equal to 1.

  - ✓ HQ_{LOAELs} for red fox, a carnivorous mammal, are less than 1.

- AE 6. Could direct contact with COPECs in sediment in each area affect the structure, function, and/or survival of the benthic invertebrate community?

  - Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to benthic invertebrate communities by exposure to COPECs in the Northern Drainage Area and Southern Drainage Area are possible.

  - This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

  - This conclusion is supported by the following MEs:

    - ✓ HQs resulting from a comparison of Northern Drainage Area sediment COPEC concentrations to ESBs protective of benthic invertebrates were greater than 1 for 7 COPECs; HQs range from 2 to 6.

    - ✓ HQs resulting from a comparison of Southern Drainage Area sediment COPEC concentrations to ESBs protective of benthic invertebrates were greater than 1 for 22 COPECs; HQs range from 3 to 872.

- AE 7. Could direct contact with COPECs in sediment in each area affect the survival and function of aquatic plant populations?

- Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to aquatic plants in the Northern Drainage Area and Southern Drainage Area are possible, but unlikely.

- This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk and considering ESBs for aquatic plants are based on toxicity to terrestrial plants.

  - This conclusion is supported by the following MEs:

    - ✓ HQs resulting from a comparison of Northern Drainage Area sediment COPEC concentrations to ESBs protective of terrestrial plants were greater than 1 for four COPECs; HQs ranged from 2 to 21, with the greatest potential for adverse effects from chromium.

    - ✓ HQs resulting from a comparison of Southern Drainage Area sediment COPEC concentrations to ESBs protective of terrestrial plants were greater than 1 for 15 COPECs; HQs range from 2 to 38, with the greatest potential for adverse effects from lead.

- AE 8. Could direct contact with COPECs in surface water in each area affect the survival and reproduction of fish and aquatic invertebrate populations?

  - Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to fish populations by exposure to COPECs in the Northern Drainage Area and Southern Drainage Area are possible, but unlikely.

  - This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

  - This conclusion is supported by the following measurement endpoint:

- ✓ HQs resulting from a comparison of Northern Drainage Area surface water COPEC concentrations (dissolved phase) to ESBs protective of fish populations were less than 1 for all COPECs, with the exception of copper (3) and lead (4).

- ✓ HQs resulting from a comparison of Southern Drainage Area surface water COPEC concentrations (dissolved phase) to ESBs protective of fish populations were less than 1 for all COPECs, with the exception of lead (3).

- AE 9. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of herbivorous avian and mammal populations?

  - Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to herbivorous avian and mammal populations by exposure to COPECs in the Northern Drainage Area and Southern Drainage Area are possible, but unlikely.

  - This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

  - This conclusion is supported by the following MEs:

    - ✓ Northern Drainage Area HQ_{LOAELs} for mallard duck, an herbivorous bird, are less than 1.

    - ✓ Northern Drainage Area HQ_{LOAELs} for muskrat, an herbivorous mammal, are less than 1.

    - ✓ Southern Drainage Area HQ_{LOAELs} for mallard duck, an herbivorous bird, are less than 1, with the exception of lead (2).

    - ✓ Southern Drainage Area HQ_{LOAELs} for muskrat, an herbivorous mammal, are less than 1, with the exception of pyrene (2).

- AE 10. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of insectivorous avian and mammal populations?

  - Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to insectivorous avian and mammal populations by exposure to COPECs in both the Northern and Southern Drainage Areas are possible.

  - This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

  - This conclusion is supported by the following MEs:

    - ✓ Northern Drainage Area HQ_{LOAELs} for tree swallow, an insectivorous bird, are less than 1, with the exception of copper (7) and lead (10).

    - ✓ Northern Drainage Area HQ_{LOAELs} for little brown bat, an insectivorous mammal, are less than or equal to 1, with the exception of copper (3).

    - ✓ Southern Drainage Area HQ_{LOAELs} for tree swallow, an insectivorous bird, are less than 1, with the exception of fluoranthene (3), copper (4), lead (224), and selenium (2).

    - ✓ Southern Drainage Area HQ_{LOAELs} for little brown bat, an insectivorous mammal, are less than or equal to 1, with the exception of fluoranthene (6), pyrene (3), copper (2) lead (26), and selenium (2).

- AE 11. Could food-chain transfer of COPECs in sediment in each area adversely affect reproductive success or survival of piscivorous avian and mammal populations?

  - Results of the exposure assessment, effects characterization, risk characterization, and uncertainty analysis indicate that adverse effects to:

    - ✓ Piscivorous avian and mammal populations by exposure to COPECs in the Northern Drainage Area are unlikely.

- ✓ Piscivorous avian populations by exposure to COPECs in the Southern Drainage Area are possible.

- ✓ Piscivorous mammal populations by exposure to COPECs in the Southern Drainage Area are unlikely.

- This is a reasonable finding based on the uncertainty inherent to the exposure and effects assessment process and the use of conservative (i.e., protective) assumptions that generally bias exposure and effects assessments toward overestimation of potential risk.

- This conclusion is supported by the following MEs:

  - ✓ Northern Drainage Area HQ_{LOAELs} for great blue heron, a piscivorous bird, are less than or equal to 1.

  - ✓ Northern Drainage Area HQ_{LOAELs} for mink, a piscivorous mammal, are less than or equal to 1.

  - ✓ Southern Drainage Area HQ_{LOAELs} for great blue heron, a piscivorous bird, are less than 1, with the exception of lead (24).

  - ✓ Southern Drainage Area HQ_{LOAELs} for mink, a piscivorous mammal, are less than 1, with the exception of lead (8).

Overall, potential ecological risks are low. The greatest potential for adverse effects is from lead. Upper-trophic-level receptors in terrestrial (i.e., American robin) and aquatic (i.e., tree swallow, great blue heron, and little brown bat) exposure areas exhibit elevated lead HQs (ranging from 3 [short-tailed shrew] to 227 [tree swallow in Southern Drainage Area]). These results are based on food web modeling that did not incorporate measures of lead bioavailability. Soil and sediment characteristics at the Facility allow for the sequestration and binding of metals, potentially reducing the fraction of lead available for uptake by receptors and reducing the potential for adverse effects. Based on the results presented in this EE/ERA and the uncertainty regarding bioavailability, additional ecological investigation and risk assessment activities at the Facility are warranted.

9.2 Recommendations

Additional ecological risk assessment activities include refining the conservative assumptions upon which modeled results are based to represent more realistic exposure scenarios. As part of this exercise, spatial analysis to define areas within the broader exposure areas with the greatest potential for risk has been conducted. These activities yielded a more realistic assessment with greater resolution and are used to focus additional data collection. As noted throughout this EE/ERA, the bioavailability of COPECs remains unknown and is conservatively assumed to be 100 percent. Understanding the bioavailability of constituents with the greatest potential for risk will be one element of the field program.

Ultimately, these activities will provide a weight-of-evidence approach to refine risk estimates and inform associated risk-based management decisions related to potential ecological risks at the Facility. The methods and results of the desktop activities, as well as proposed elements of a subsequent field program, are provided in an Ecological Risk Assessment Work Plan, presented in Appendix F. The field program will be implemented during the summer (biological field season) in 2016 such that the results can inform ongoing remedial decisions.

Notes:

[1] Species observations made during July 2010 and July 2011 habitat characterizations.

X* = Dominant species

USFWS = United States Fish and Wildlife Service

The following are the USFWS hydrophytic classifications for the observed species:

OBL = a plant species generally (>99% of the time) only found in wetlands under natural conditions

FACW = a plant species usually (>66% to 99% of the time) found in wetlands, but which may be found occasionally in uplands under natural conditions

Note: a negative sign (-) indicates a species less frequently found in wetlands, a positive sign (+) indicates a species more frequently found in wetlands, and a star sign (*) indicates a tentative status.

FAC = a plant species sometimes (>33% to 66% of the time) found in wetlands, but which may also be found commonly in uplands

FACU = a plant species seldom (<33% of the time) found in wetlands, but which may also be found commonly in uplands

UPL = a plant species generally (>99% of the time) found only in uplands under natural conditions

NL = a plant species that is not listed

NI = insufficient information was available to determine an indicator status

NA = not available

Table 3-1 - Areas of Presumed Remedial Action
Ecological Evaluation / Ecological Risk Assessment
Kenvil Works Facility
Kenvil, New Jersey

	Area of Presumed Remedial Action	History	Fate and Transport	Remedial Objective
Tier I	TNT Area (conglomerate of adjacent areas of concern)	One of the earliest developed portions of the Facility as well as the Facility of one of the most powerful explosions in the history of the Facility. This area of the Facility produced explosives for more than a century; during this period operational procedures and incidental release of materials affected soil and groundwater quality. Areas of stressed vegetation, as well as areas devoid of vegetation (former footprint of Building 666 that exploded in 1917) are visible. Stained soil and discolored water have been observed in a former lagoon area (depression in ground surface) where overburden groundwater interacts with surface soil and discharges becoming surface water.	Constituent distribution in this areas occurred primarily during process upsets (e.g., explosions, spills). Following these incidents, the ground surface was leveled and new structures built, these activities further distributed source material (e.g., crystalline TNT, inorganic lead chunks) into the upper few feet of the soil column. Over time, precipitation mobilized constituents in soil to groundwater. TNT in soil influences groundwater quality in this area of the Facility. Groundwater discharges to the southern wetland complex adjacent to the Dynamite/TNT area. The absence of source area constituents in these wetland features is likely related to strong reducing conditions in sediment and associated biological degradation of dissolved phase constituents as groundwater discharges through the sediment. In the southwestern corner of the Facility, TNT in groundwater migrates offsite, however, the plume is delineated beneath a shopping plaza parking lot and no exposure pathway linking TNT in groundwater to offsite ecological receptors exists.	Hercules is evaluating a combination of source removal, bioremediation, and monitored natural attenuation to address constituent concentrations (primarily TNT and its breakdown products) in this area.
Tier II	Ammonium Nitrate Area – Former Burning Ground and intervening areas of concern (H12-237, H13-1, H13-7)	From the beginning of production onsite through the end of WWI, off-specification product and residual materials were transported via rail car to the WWI Burning Grounds (near the AN Area and wastewater treatment plant). The contents of the rail car were emptied down a slope where the materials were incinerated in place on the ground surface. Currently, the area supports sparse vegetation and the ground surface contains a non-combustible fraction of the waste materials (e.g., ceramic, metal) and related constituents in soil (e.g., metals, PAHs).	Given the surficial nature of the activities conducted in this area, debris and constituents in soil do not extend beyond the surface soil. No interaction with groundwater is evident, and would not be expected based on the topography of the area and associated groundwater table elevations. In the absence of vegetation, erosion of surficial soil is possible and may result in localized transport of constituents at/near the perimeter of the area of concern.	The presumptive remedy for this area involves excavation of soil and comingled debris, backfilling with clean fill and restoration of vegetative cover. Excavated material may be disposed of offsite or consolidated and contained elsewhere onsite. Additional study is needed to guide final disposition of the excavated material.
	B-Line Area – Disposal Area (M8-1)	This area served as a disposal area for solid waste materials during the period of increased production surrounding World War II (WWII). The area currently consists of a low-lying depression with visible surface debris. Vegetation is moderate to sparse and consists of grasses and shrubs. The area occurs between Duck Pond and an emergent/forested wetland complex.	The groundwater table is at or near the ground surface in this areas throughout the year. The material disposed of consists of empty metal containers, concrete debris, and off-spec fiberglass motor housings. This debris, while potentially emplaced below the groundwater table, are not expected to contain constituents that would leach to groundwater. Groundwater monitoring wells in proximity to the disposal area confirm this expectation.	The presumptive remedy will include a combination of removal and offsite disposal, debris consolidation and capping while minimizing disturbance to freshwater wetlands. Pre-design investigation activities will include test pitting to refine the perimeter of the disposal area and further characterize the emplaced material.
	Diazo Pond (H8-1)	The Diazo Pond is a remnant operational feature located in the Diazo Area. Historical diazo production processes generated a spent acid sludge that was neutralized via a sodium hydroxide bath and then disposed of in a shallow man-made lagoon (pond). Over time the production process changed and the sludge was managed to reclaim/reuse certain production materials rather than being disposed of. The pond area was covered with soil. SI test pit investigations identified layers of sludge comingled with soil in the location of the former disposal pond.	Constituents present in the spent acid sludge are generally immobile and bound in the sludge/soil mixture. This area is abutted by other upland areas of the Facility and the depth of the sludge/soil mixture does not extend into the groundwater table. Related constituents have not been identified above applicable standards in downgradient groundwater monitoring wells.	Analytical testing indicates that the sludge contains metals and PAHs at levels consistent with other areas of former operations. However, the sludge creates additional geotechnical stability concerns associated with future reuse of this area of the Facility. Additional investigation of the physical and chemical properties of the soil/sludge mixture are underway. The results of these studies will inform design of an appropriate remedy. Reuse onsite following dewatering/stabilization may represent a viable option, as does excavation and disposal at a licensed offsite facility.

Table 3-1 - Areas of Presumed Remedial Action
Ecological Evaluation / Ecological Risk Assessment
Kenvil Works Facility
Kenvil, New Jersey

	Area of Presumed Remedial Action	History	Fate and Transport	Remedial Objective
Tier II (cont.)	B-Line Area - Dinitrotoluene (DNT) Heater House (L11-2091)	During demolition of Facility structures crystalline DNT was identified within the concrete walls and slab of the DNT Heater House. DNT in the concrete rubble and soil represents a source of DNT to surrounding soil and groundwater.	Crystalline DNT is soluble and migrates readily through the soil column to groundwater via precipitation/infiltration. Soil samples surrounding the former structure confirmed the presence of DNT in soil, DNT is also present in nearby groundwater monitoring wells. There are no surface water bodies in proximity to this area of concern.	The presumptive remedy includes disposal of remaining concrete rubble potentially containing DNT residues, excavation of soil beneath former structure footprint, and monitored natural attenuation for residual influences in groundwater.
	Development Area – Old Burning Ground and adjacent areas of concern to the southwest (M5-3, L5-2313, L5-10, L5-2275, L5-539)	The burning area was used to dispose off-spec and residual energetic materials and was situated in a low-lying area adjacent to Duck Pond. Duck Pond provided a source of water and a buffer from nearby forested areas. Currently, the area supports sparse vegetation and the ground surface contains a non-combustible fraction of the waste materials (e.g., metal, ceramic).	The topography of the old burning grounds slopes down towards the northern end of Duck Pond. The absence of vegetation creates conditions where stormwater runoff and overland flow can erode surface soil and associated constituents (i.e., metals, PAHs, E&E) into the sediment at the northern end of Duck Pond. Duck Pond bathymetry confirms that deposition is greatest along the northern shoreline adjacent to the burning grounds. Infiltration of precipitation and runoff do not appear to influence local groundwater quality based on recent groundwater quality monitoring results.	The presumptive remedy involves a combination of debris/hot spot removal, and isolation and capping of the remaining material. Given the low-lying topography of the area and proximity to Duck Pond, this area may serve as a consolidation site in the event that sediment is removed from Duck Pond or for similar materials generated elsewhere onsite during remedial activities (e.g., Ammonium Nitrate Area – Former Burning Ground soil).
Tier III	Storage Area – Disposal Area (N6-1)	This area served as a disposal area for solid waste materials during the period of increased production associated with WWI and the years that followed. Over time, soil has been placed/accumulated at the ground surface and the area has almost entirely revegetated with grasses and shrubs. Miscellaneous debris is present at ground surface in places. A focused removal of large metal debris occurred concurrent with Facility demolition.	This area lies at a topographic high spot onsite, well above the underlying groundwater table. Similar to the B-Line disposal area, the buried waste consists primary of solid, metal containers and similar scrap material. Constituents in soil do not appear mobile and may be related more to the fill material place atop the debris than the debris itself. The area is heavily vegetated, reducing the liklihood of erosion or wind scour of surface soil. Soil and associated constituents in this area appear stable and generally immobile.	Hercules will address the removal and/or containment of these materials during the feasibility study (FS) process. Additional evaluation and assessment of this area may be required to select an appropriate remedy.
	B Line Area - South (conglomerate of adjacent areas of concern)	Various process buildings and structures (e.g., basins, sheds) existed at the southern end of the B-Line Area near the terminus of Powder Mill Road. During decommissioning and demolition activities, residual product was observed in soil at various locations in this area and interim remedial measures (e.g., excavation) implemented. A review of SI/RI sample results identified an aggregation of locations surrounding former structures that share similar Facility-related influences approximately 11 acres in size.	This area does not occur in proximity to surface water features, and constituents detected in this area (i.e., metals and PAHs) do not appear to be influencing groundwater quality. Localized erosion and transport of surface soil and associated constituents may occur, however, the dense vegetation established in this area likely minimizes those influences. Soil and associated constituents in this area appear stable and generally immobile.	Hercules will address removal and/or containment these materials during the FS process. Additional evaluation and assessment of this area is required to refine the extente of Facility-related influences and select an appropriate remedy (where applicable).
	A Line Area - Northwest (conglomerate of adjacent areas of concern)	Historical records indicate that two buildings in the northwestern corner of the A-Line Area were destroyed during a fire and explosion. The buildings were later rebuilt on the Facility of the incident. During the SI/RI investigation and decommissioning and demolition activities, evidence of explosions (e.g., physical debris and residual source material) were identified in the area surrounding the former building locations. A review of SI/RI sample results identified two areas where these historical influences were evident.	This portion of the former operational area is relatively flat and well vegetated. Historical influences occur primarily in surface soil, and do not appear mobile in groundwater based on recent groundwater quality data. The dense vegetation throughout the area preclude erosion or wind scour of surface soils. Soil and associated constituents in this area appear stable and generally immobile.	Hercules will address the removal and/or containment of these materials during the FS process. Additional evaluation and assessment of this area is required to refine the extente of Facility-related influences and select an appropriate remedy (where applicable).

Table 3-2
Assessment and Measurement Endpoints
Ecological Risk Assessment
Kenvil Works Facility
Kenvil, New Jersey

Exposure Medium	Exposure Areas		Rationale	Receptor Group	Assessment Endpoint	Measurement Endpoint	Target Species
Soil	Terrestrial	Former Operational Areas and Undeveloped Areas	*Former Operational Areas:* Contiguous area of site that has similar historical uses and potential for operational impacts; subject to future redevelopment. *Undeveloped Areas:* Contiguous area of site that remained undeveloped during site's known history; proposed as conservation area during site redevelopment.	Terrestrial Plant Community - Structure, Function, Survival	1. Could direct contact with COPECs in site soil affect the structure, function, and/or survival of the terrestrial plant community?	1. Compare concentrations of COPECs in soil to ESBs protective of plants.	NA
				Terrestrial Invertebrate Community - Survival and Reproduction	2. Could direct contact with COPECs in site soil affect the structure, function, and/or survival of the terrestrial invertebrate community?	2. Compare concentrations of COPECs in soil to ESBs protective of terrestrial invertebrates.	NA
				Herbivorous Avian and Mammal Populations - Survival and Reproduction	3. Could food-web transfer of COPECs in site soil adversely affect reproductive success or survival of herbivorous avian and mammal populations?	3. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for herbivorous birds and mammals.	Northern Bobwhite; White-tailed Deer
				Insectivorous Avian and Mammal Populations - Survival and Reproduction	4. Could food-web transfer of COPECs in site soil adversely affect reproductive success or survival of insectivorous avian and mammal populations?	4. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for insectivorous birds and mammals.	American Robin; Short-tailed Shrew
				Carnivorous Avian and Mammal Populations - Survival and Reproduction	5. Could food-web transfer of COPECs in site soil adversely affect reproductive success or survival of carnivorous avian and mammal populations?	5. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for carnivorous birds and mammals.	Red-Tailed Hawk; Red Fox
Sediment and Surface Water	Aquatic	Northern Drainage Area (Duck Pond, miscellaneous ponds, tributaries) Southern Drainage Area (drainage areas and wetland complex)	*Ponds and Tributaries:* Perennial aquatic habitat features onsite, located amidst historic operational areas; miscellaneous ponds are isolated surface-water features that provide semi-aquatic habitat. *Drainage Areas and Wetland Complex:* Linear intermittent drainage features drain historic operational areas to the undeveloped wetland complex, which consists of perennial aquatic habitat consisting of both flowing and non-flowing water bodies.	Aquatic Plant Populations - Structure, Function, Survival	6. Could direct contact with COPECs in sediment in each area affect the survival and function of aquatic plant populations?	6. Compare concentrations of COPECs in sediment and surface water in the Northern and Southern Drainage Areas to ESBs protective of terrestrial plants.	NA
				Benthic Community - Structure, Function, Survival	7. Could direct contact with COPECs in sediment in each area affect the structure, function, and/or survival of the benthic invertebrate community?	7. Compare concentrations of COPECs in sediment in the Northern and Southern Drainage Areas to ESBs protective of benthic invertebrates.	NA
				Fish and Aquatic Invertebrate Populations - Survival and Reproduction	8. Could direct contact with COPECs in surface water in each area affect the survival and reproduction of fish and aquatic invertebrate populations?	8. Compare concentrations of COPECs in surface water in the Northern and Southern Drainage Areas to ESBs protective of fish and aquatic invertebrates.	NA
				Herbivorous Avian and Mammal Populations - Survival and Reproduction	9. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of herbivorous avian and mammal populations?	9. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for herbivorous birds and mammals in the Northern and Southern Drainage Areas.	Mallard Duck; Muskrat
				Insectivorous Avian and Mammal Populations - Survival and Reproduction	10. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of insectivorous avian and mammal populations?	10. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for insectivorous birds and mammals in the Northern and Southern Drainage Areas.	Tree Swallow; Little Brown Bat
				Piscivorous Avian and Mammal Populations - Survival and Reproduction	11. Could food-web transfer of COPECs in sediment in each area adversely affect reproductive success or survival of piscivorous avian and mammal populations?	11. Compare modeled dietary COPEC exposure to TRVs (calculate HQs) for piscivorous birds and mammals in the Northern and Southern Drainage Areas.	Great Blue Heron; Mink

Notes:
COPEC = constituent of potential ecological concern
ESB = ecological screening benchmark
HQ = hazard quotient
NA = not applicable
TRV = toxicity reference value

Notes:

1. New Jersey Department of Environmental Protection (NJDEP) value from Ecological Screening Criteria (ESC) Table (NJDEP 2009)
2. Resource Conservation and Recovery Act Region 5 Ecological Screening Level (United States Environmental Protection Agency [USEPA
3. Ecological Soil Screening Value (EcoSSL) (USEPA 2007)
4. Kuperman et al. 2009. In Ecotoxicology of Explosives. Sunahara et al. (eds). CRC Press.
6. Talmage et al. 1999
7. NJDEP Lowest Effects Level value
8. NJDEP Severe Effects Level value
9. Region 3 Biological Technical Assistance Group Freshwater Sediment Screening Benchmarks (USEPA 2006)
10. Verbruggen et al. 2001
11. Pascoe et al. 2010
12. Some constituents were analyzed under multiple analytical methods but are presented once in the table.
13. Metals screening values based on average hardness of 57 milligrams per liter (mg/L) calcium carbonate ($CaCO_3$) in Northern Drainage A and 120 mg/L CaCO3 in Southern Drainage Area. Values for the Northern Drainage Area designated with an "n" while values for the Southern Drainage Area are designated with an "s"
14. Value calculated as a function of pH based on NJDEP ESC Table.
15. Analyte detected fewer than five times and screens out based on frequency of detection. Screening value not necessary.
16. Schafer et al. 1985
17. Value for nitrobenzene used as a surrogate.
18. Conservative high molecular weight polycyclic aromatic hydrocarbons from EcoSSL Table.
19. Analyte considered an essential nutrient; therefore, a screening level is not necessary.
20. Value for nitroglycerin used as a surrogate.
21. Chronic value for 2-amino-4,6-dinitrotoluene used as a surrogate.
22. Value for benzo(b)fluoranthene used as a surrogate.
23. Mattice et al. 1981
24. Dhawan et al. 1999
25. Value for 2-methylnaphthalene used as a surrogate.
26. Screening value is organic carbon normalized. Converted to site-specific screening value based on an average organic carbon of 13.3% in the Northern Drainage Area and 5.8% in the Southern Drainage Area.
27. Value for saline water in the NJDEP ESC Table used for lack of a freshwater value.

-- = not applicable
CAS = Chemical Abstract Service
mg/kg = milligram per kilogram
NA = not available
PCB = polychlorinated biphenyl
SVOC = semivolatile organic compound
TPH = total petroleum hydrocarbon
µg/L = microgram per liter
VOC = volatile organic compound

Notes:
1. Aluminum is not considered a COPEC because site soil pH (6.1) is above the level where aluminum toxicity occurs (<5.5) per USEPA 2003b.
COPEC = constituent of potential ecological concern
HQ = hazard quotient
LOW FOD = low frequency of detection
mg/kg = milligrams per kilogram
NA = not available
N = no
Nutrient = screened out to due status as essential nutrient
ug/kg = micrograms per kilogram
Y = yes

Perchlorate									
Perchlorate	--	--	0/2	-	--	5 - 5	ND	N	ND

Notes:
-- = not applicable
< = less than
> = greater than
AQ = aqueous
COPEC = constituent of potential ecological concern
FOD = frequency of detection
HQ = hazard quotient
N = no
NA = not available
ND = not detected
SVOC = semivolatile organic compound
TPH = total petroleum hydrocarbon
µg/L = micrograms per liter
VOC = volatile organic compound
Y = yes

Notes:

-- = not applicable
< = less than
> = greater than
AQ = aqueous
COPEC = constituent of potential ecological concern
FOD = frequency of detection
HQ = hazard quotient
N = no
NA = not available
ND = not detected
SVOC = semivolatile organic compound
TPH = total petroleum hydrocarbon
µg/L = micrograms per liter
VOC = volatile organic compound
Y = yes

Notes:

[1] Distribution assessed by goodness-of-fit tests based on detected values only conducted using ProUCL 4.1.00 at a 95% confidence level (α = 0.05).
Distributions:
Normal: dataset follows a normal distribution, according to the Shapiro-Wilk test.
Gamma: dataset follows a gamma distribution, according to the Kolmogorov-Smirnov test.
Nonparametric: dataset does not follow a normal distribution.

[2] 95UCLs calculated on datasets with sample size greater than or equal to 8 and detects greater than or equal to 5. The average of the detected constituents or the minimum detection limit was selected for duplicate samples.

[3] The exposure point concentration is the 95UCL when available (i.e., sample size greater than or equal to 8 with a minimum of 5 detections).

[4] Considered bioaccumulative according to USEPA 2000 and NJDEP 2015.

[5] Although not considered bioaccumulative, explosive compounds were included in the dose-exposure model based on their direct ties to the site operational history.

% = percent
95UCL = 95% upper confidence limit of the mean
COPEC = constituent of potential ecological concern
FOD = frequency of detection
KM = Kaplan-Meier
mg/kg = milligram per kilogram
n = sample size
NJDEP = New Jersey Department of Environmental Protection
PCB = polychlorinated biphenyl
SVOC = semivolatile organic compound
USEPA = United States Environmental Protection Agency
VOC = volatile organic compound

Zinc (AQ - dissolved)	89	67	3.4-89.6	75	Nonparametric	15	90	15	95% KM (BCA) UCL

Notes:

[1] Distribution assessed by goodness-of-fit tests based on detected values only conducted using ProUCL 4.1.00 at a 95% confidence level (α = 0.05).
Distributions:
Normal: dataset follows a normal distribution, according to the Shapiro-Wilk test.
Gamma: dataset follows a gamma distribution, according to the Kolmogorov-Smirnov test.
Nonparametric: dataset does not follow a normal distribution.

[2] 95UCLs calculated on datasets with sample size greater than or equal to 8 and detects greater than or equal to 5. The average of the detected constituents or the minimum detection limit was selected for duplicate samples.

[3] The exposure point concentration is the 95UCL when available (i.e., sample size greater than or equal to 8 with a minimum of 5 detections). The maximum detected concentration was selected as the exposure point concentration for constituents with less than 5 detections.

[4] No dissolved data for aluminum and manganese. Total metal data used in lieu of dissolved.

-- = not applicable
% = percent
95UCL = 95% upper confidence limit of the mean
AQ = aqueous
COPEC = constituent of potential ecological concern
FOD = frequency of detection
KM = Kaplan-Meier
n = sample size
NA = not available/applicable
NJDEP = New Jersey Department of Environmental Protection
µg/L = microgram per liter
USEPA = United States Environmental Protection Agency

Exposure Point Concentrations for Southern Drainage Area Sediment
Ecological Risk Assessment
Kenvil Works Facility
Kenvil, New Jersey

Notes:

[1] Distribution assessed by goodness-of-fit tests based on detected values only conducted using ProUCL 4.1.00 at a 95% confidence level (α = 0.05).
Distributions:
Normal: dataset follows a normal distribution, according to the Shapiro-Wilk test.
Gamma: dataset follows a gamma distribution, according to the Kolmogorov-Smirnov test.
Nonparametric: dataset does not follow a normal distribution.

[2] 95UCLs calculated on datasets with sample size greater than or equal to 8 and detects greater than or equal to 5. The average of the detected constituents or the minimum detection limit was selected for duplicate samples.

[3] The exposure point concentration is the 95UCL when available (i.e., sample size greater than or equal to 8 with a minimum of 5 detections). The maximum detected concentration was selected as the exposure point concentration for constituents with less than 5 detections.

[4] Considered bioaccumulative according to USEPA 2000 and NJDEP 2015.

[5] Although not considered bioaccumulative, explosive compounds were included in the dose-exposure model based on their direct ties to the site operational history and general ubiquity within certain former operational areas.

% = percent
95UCL = 95% upper confidence limit of the mean
COPEC = constituent of potential ecological concern

Notes:

a. Nagy 2001

b. USEPA 1993

c. Daily ingestion rates converted to dry weight assuming a moisture content of the following (USEPA 2007):
Invertebrates: 84%
Tissue: 68%
Plants: 85%

d. Beyer et al. 1994 (muskrat based on values for woodchuck; robin based on values for woodcock; bobwhite based on values for wild turkey)

e. USEPA 2007

f. Conservative estimates

g. Aerial insectivore; therefore, soil/sediment ingestion assumed to be neglible (Sample and Suter 1994).

h. Calculated by multiplying the soil ingestion rate times the dry weight daily ingestion rate.

i. Calculated using the allometric equation for non-passerines from USEPA 1993.

% = percent

kg = kilogram

kg/day dw = kilogram per day dry weight

kg/day ww = kilogram per day wet weight

USEPA = United States Environmental Protection Agency

Notes:

a. Ecological soil screening levels (EcoSSLs) (2003-2008). EcoSSLs identify the NOAEL; the LOAEL is from either the corresponding study, or is extrapolated from the NOAEL using a multiplying factor of 10. USEPA did not identify a TRV for PAHs for birds; therefore, the lowest reported effect level from the studies assigned an Evaluation Score greater than 10 was used.

Notes:

-- = not applicable
C = concentration
COPEC = constituent of potential ecological concern
EPC = exposure point concentration
HQ = hazard quotient
kg = kilogram
kg/day = kilogram per day
LOAEL = lowest observed adverse effects level
mg/kg = milligram per kilogram
mg/kg/d = milligram per kilogram per day
NA = not available
NOAEL = no observed adverse effects level
PCB = polychlorinated biphenyl
SVOC = semivolatile organic compound
TRV = toxicity reference value

Table 7-9
Summary of Hazard Quotients for Terrestrial Wildlife
Ecological Risk Assessment
Kenvil Works Facility
Kenvil, New Jersey

COPECs	American Robin		Northern Bobwhite		Red-Tailed Hawk		Short-Tailed Shrew		White-Tailed Deer		Red Fox	
	NOAEL	LOAEL	NOAEL	LOAEL	NOAEL	LOAEL	NOAEL	LOAEL	NOAEL	LOAEL	NOAEL	LOAEL
Pesticides/PCBs												
Total PCBs	**42**	**3**	≤1	≤1	≤1	≤1	**4**	≤1	≤1	≤1	≤1	≤1
Metals												
Copper	**8**	**3**	≤1	≤1	≤1	≤1	**2**	≤1	≤1	≤1	≤1	≤1
Lead	**51**	**25**	≤1	≤1	**2**	<1	**5**	**3**	≤1	≤1	≤1	≤1
Mercury	**2**	≤1	≤1	≤1	≤1	≤1	≤1	≤1	≤1	≤1	≤1	≤1
Zinc	**2**	≤1	≤1	≤1	≤1	≤1	≤1	≤1	≤1	≤1	≤1	≤1

Notes:
Bolded values indicate HQ>1.
≤ = less than or equal to
COPEC = constituent of potential ecological concern
LOAEL = lowest observed adverse effects level
NOAEL = no observed adverse effects level
PCB = polychlorinated biphenyl

Table 7-10
Hazard Quotients for Benthic Invertebrates - Northern Drainage Area
Ecological Risk Assessment
Kenvil Works Facility
Kenvil, New Jersey

COPECs	Screening Value (mg/kg)	Exposure Point		Hazard Quotients	
		Maximum Detected (mg/kg)	95UCL (mg/kg)	Maximum Detected	95UCL
SVOCs					
Benzo(a)anthracene	0.32	2.1	0.4	7	1
Benzo(a)pyrene	0.37	1.5	0.3	4	0.9
Benzo(g,h,i)perylene	0.17	1.3	0.3	8	1
Benzo(k)fluoranthene	0.24	1.7	0.3	7	1
Chrysene	0.34	2.9	0.5	9	1
Fluoranthene	0.75	2.2	0.7	3	1.0
Phenanthrene	0.56	1.1	0.2	2	0.4
Pyrene	0.49	4.0	0.9	8	**2**

Explosives and Energetics						
Nitrocellulose	NA	-	6000	305	NA	NA
Nitroglycerin	NA	-	2700	123	NA	NA

Notes:
Bolded values indicate a hazard quotient based on the 95UCL that is greater than 1.
a. Value for chrysene (HMW PAH) used as surrogate.
b. Efroymson et al. 1997b
c. Ecotox database (value is NOAEL for black poplar [*Populus nigra*] from Wittig et al. 2003).
d. Sverdrup et al. 2003
e. Ecological soil screening levels
- = not applicable
95UCL = 95th percentile upper confidence limit of the mean
COPEC = constituent of potential ecological concern
HMW = high molecular weight
mg/kg = milligram per kilogram
NA = not available
SVOC = semivolatile organic compound

Table 7-12
Hazard Quotients for Fish and Aquatic Invertebrates - Northern Drainage Area
Ecological Risk Assessment
Kenvil Works Facility
Kenvil, New Jersey

COPEC	EPC (µg/L)	Screening Value (µg/L)	HQ
Metals - Dissolved			
Copper	17	5.2	3
Lead [a]	20	5.4	4
Nickel	4	27	0.1
Zinc	103	70.4	1

Notes:
Screening values from Table 4-2.

[a] Screening value for total metal used as surrogate in absence of dissolved metal screening value.

95UCL = 95% upper confidence limit of the mean
COPEC = constituent of potential ecological concern
EPC = exposure point concentration, equivalent to the 95UCL
HQ = hazard quotient
µg/L = microgram per liter

Table 7-13
Hazard Quotients for Tree Swallow - Northern Drainage Area
Ecological Risk Assessment
Kenvil Works Facility
Kenvil, New Jersey

Nitrocellulose	NA	-	2200	146.8	NA	NA

Notes:

Bolded values indicate a hazard quotient based on the 95UCL that is greater than 1.

a. Value for chrysene (HMW PAH) used as surrogate.

b. Efroymson et al. 1997b

c. Value for di-n-butylphthalate used as a surrogate.

d. Ecotox database (value is NOAEL for black poplar [*Populus nigra*] from Wittig et al. 2003).

e. Sverdrup et al. 2003

f. Ecological soil screening levels

g. Sunahara et al. 2009 (Table 12.5 for weathered and aged)

h. Value for acenaphthene used as surrogate

i. Value for TNT used as surrogate (Talmage et al. 1999)

-- = not applicable

95UCL = 95th percentile upper confidence limit of the mean

COPEC = constituent of potential ecological concern

HMW = high molecular weight

mg/kg = milligram per kilogram

NA = not available

SVOC = semivolatile organic compound

Table 7-21
Hazard Quotients for Fish and Aquatic Invertebrates - Southern Drainage Area
Ecological Risk Assessment
Kenvil Works Facility
Kenvil, New Jersey

COPEC	EPC (µg/L)	Screening Value (µg/L)	HQ
Metals - Total [a]			
Aluminum	664	87	8
Manganese	1274	120	11
SVOCs			
Chrysene	0.3	0.28	1
Metals - Dissolved			
Cadmium [b]	--	--	--
Arsenic [c]	5.3	150	0.04
Copper	3.4	9.9	0.3
Lead [c]	18	5.4	3
Mercury [c]	0.1	0.77	0.1
Selenium [c]	5.2	5	1
Silver	2.1	4.4	0.5
Zinc	15	133	0.1

Notes:
Screening values from Table 4-2.

[a] Total metal data used due to a lack of dissolved data.

[b] Cadmium screened based on total metal data; however, it was non-detect for all dissolved s and, therefore, it is not ecologically relevant.

[c] Screening value for total metal used for lack of dissolved metal screening value.

-- = not applicable
95UCL = 95% upper confidence limit of the mean
COPEC = constituent of potential ecological concern
EPC = exposure point concentration, equivalent to the 95UCL
HQ = hazard quotient
NA = not available
µg/L = microgram per liter

Notes:

Bolded values indicate a hazard quotient that is greater than 1.

- - = not applicable
C = concentration
COPEC = constituent of potential ecological concern
EPC = exposure point concentration
HQ = hazard quotient
kg = kilogram
kg/day = kilogram per day
LOAEL = lowest observed adverse effects level
mg/kg = milligram per kilogram
mg/kg/d = milligram per kilogram per day
NA = not available
NOAEL = no observed adverse effects level
SVOC = semivolatile organic compound
TRV = toxicity reference value
